CLINICAL DISORDERS

CARDIOVASCULAR DISEASES	SECTION
Acute coronary syndromes	I
Aneurysm, abdominal aorta	I
Angina pectoris	I
Aortic coarctation	I
Aortic dissection	I
Aortic regurgitation	I
Aortic stenosis	I
Arrhythmogenic right ventricular cardiomyopathy	I
Atrial enlargement, left atrium	II
Atrial fibrillation	I
Atrial flutter	I
Atrial myxoma	I
Atrial septal defect	I
Atrium enlargement, right atrium	II
Atrioventricular dissociation	I
Bicuspid aortic valve	I
Branch bundle block	I
Bradycardia	III
Brugada syndrome	I
Calcifications, cardiac on x-ray	II
Calcifications, valvular on x-ray	II
Cardiac death, sudden	II
Cardiac tamponade	I
Cardiac tumors	II
Cardioembolism	II
Cardiomegaly on chest x-ray	III
Cardiomyopathy, chemical-induced	I
Cardiomyopathy, dilated	I
Cardiomyopathy, hypertrophic	I
Cardiomyopathy, ischemic, surgical management	III
Cardiomyopathy, restrictive	I
Cardiorenal syndrome	I
Carotid sinus syndrome	I
Cervical artery dissection	I
Chronic urticaria	I
Cirrhotic cardiomyopathy	I
Congestive heart failure	I
Congestive heart failure and cardiomyopathy	II
Connective tissue disease–associated vasculitis	I
Coronary artery disease	I
Cor pulmonale	I
Cyanosis	II
Early repolarization syndrome	I
Ejection sound or click	II
Giant cell myocarditis	I
Heart block, second-degree	I
Heart failure, acute	I, II
Heart failure, pregnancy	II
HIV-associated cardiomyopathy	I
Hypercholesterolemia	I
Hyperlipoproteinemia, primary	I
Hypertension	I
Hypertension, in children	II
Hypotension	III
Intraventricular conduction defect (IVCD)	I
Junctional rhythm	I
Long QT syndrome	I
Mesenteric arterial embolism, associated factors	II
Mitral regurgitation	I
Mitral stenosis	I
Mitral valve prolapse	I
Multifocal atrial tachycardia	I
Murmur, diastolic	III
Murmur, systolic	III
Myocardial infarction	I
Myocarditis	I
Orthostatic hypotension	I
Palpitations	III
Paroxysmal supraventricular tachycardia	I
Patent ductus arteriosus	I
Pericardial effusion, malignant	III
Pericarditis	I
Pleural effusion, malignant	III
Pleural effusions, malignancy-associated	II
Postural hypotension, nonneurologic causes	II
Premature ventricular contractions and ventricular tachycardia	II
Pulmonary edema	I
Pulmonary edema, non-cardiogenic	II
Pulseless electrical activity	I
Renal artery stenosis	I
Rib notching on x-ray	II
Short QT syndrome	I
Sick sinus syndrome	I
Syncope	I
Tachycardia	III
Tachycardia, narrow complex	III
Tachycardia, wide complex	III
Takayasu's arteritis	I
Takotsubo cardiomyopathy	I
Thrombotic microangiopathies, diagnosis	III
Torsades des pointes	I
Valvular heart disease	II
Venous ulcers	I
Ventricular septal defect	I
Ventricular fibrillation	I, III
Ventricular tachycardia	I
Wolff-Parkinson-White syndrome	I

DERMATOLOGY	
Acne vulgaris	I
Actinic keratosis	I
Alopecia	I
Angioedema	I
Angular cheilitis	I
Atopic dermatitis	I
Balanitis	I
Basal cell carcinoma	I
Bedbug bite	I
Calcifications, cutaneous	II
Candidiasis, cutaneous	I
Contact dermatitis	I
Cutaneous infections, athletes	II
Cutaneous occlusion syndromes	III
Cyanosis, algorithm	III
Dermatitis herpetiformis	I
Discoid lupus	I
Eosinophilic dermatoses	III
Epidermolysis bullosa (EB)	I
Erosions, genitalia	II
Erysipelas	I
Erythema elevatum diutinum	I
Erythema multiforme	I
Erythroderma	II
Eyelid neoplasm	II
Fifth disease (parvovirus infection)	I
Finger lesions, inflammatory	II
Flushing	III
Folliculitis	I
Foot dermatitis	II
Genital lesions or ulcers	III
Granuloma, algorithm	III
Granuloma annulare	I
Granulomatous dermatitides	II
Hand-foot-mouth disease	I
Herpes simplex	I
Herpes zoster	I
Hidradenitis suppurativa	I
Hyperhydrosis	I
Hyperpigmentation	III
IgA vasculitis	I
Impetigo	I
Jaundice, neonatal, algorithm	III
Kaposi sarcoma	I
Leg ulcer	III
Lichen planus	I
Lichen sclerosus	I
Lichen simplex chronicus	I
Malar eruption	III
Mastocytosis	I
Melanoma	I
Melanonychia	II
Molluscum contagiosum	I
Mucormycosis	I
Myositis	III
Nail dystrophy	III
Neurofibromatosis	I
Onycholysis	III
Oral hairy leukoplakia	I
Panniculitis	I
Papulosquamous disorders, pediatric patient	III
Paronychia	I
Pediculosis	I
Pemphigus vulgaris	I
Photosensitivity	III
Pinworms	I
Pityriasis rosea	I
Porphyrias	I
Premature graying, scalp hair	II
Pruritus, generalized, clinical algorithm	III
Pruritus vulvae	II
Psoriasis	I
Purpura, nonpalpable	II
Purpura, non-purpuric disorders simulating purpura	II
Purpura, palpable	II
Purpura, palpable, clinical algorithm	III
Reactive erythema, pediatric patient	III
Rocky Mountain spotted fever	I
Rosacea	I
Roseola	I
Scabies	I
Scarlet fever	I
Scleroderma (systemic sclerosis)	I
Skin blisters	III
Stevens-Johnson syndrome	I
Tinea capitis	I
Tinea corporis	I
Tinea cruris	I
Tinea pedis	I
Tinea versicolor	I
Varicella	I
Venous insufficiency, chronic	I
Venous ulcers	I
Verrucous lesions	II
Vitiligo	I
Warts	I

ENDOCRINOLOGY	
Adrenal incidentaloma	I, III
Adrenal insufficiency	I
Adrenal mass, clinical algorithm	III
Adrenocortical hyperfunction	II
Adrenocortical hypofunction	II
Aldosteronism	I
Androgen excess, reproductive-age woman	II
Anhydrosis	II
Bone density, decreased, generalized	II
Bone density, decreased, localized	II
Bone mass, low	II
Breast, nipple discharge evaluation	III
Calcifications, abdominal, nonvisceral on x-ray	II
Calcifications, adrenal gland on x-ray	II
Calcifications, genital tract, female on x-ray	II
Calcium stones	II
Cushing's disease and syndrome	I
Delayed puberty	I
Diabetes insipidus	I
Diabetes mellitus	I
Diabetic foot	I
Diabetic gastroparesis	I
Diabetic ketoacidosis	I
Diabetic nephropathy	I
Erectile dysfunction	I
Exocrine pancreatic insufficiency (EPI)	I
Flushing	III
Foot lesion, ulcerating	II
Galactorrhea	I
Genitourinary syndrome of menopause (GSM)	I
Goiter evaluation and management	III
Graves disease	I
Gynecomastia	I
Hirsutism	I
Hot flashes	I
Hypercalcemia, clinical algorithm	IV
Hypercalcemia, laboratory differential diagnosis	II
Hypercalcemia, malignancy-induced	II
Hyperlipoproteinemia, primary	I
Hyperosmolar hyperclycemic syndrome	I
Hyperostosis, cortical bone	II
Hyperparathyroidism	I
Hyperthyroidism	I
Hypoaldosteronism	I
Hypocalcemia, laboratory differential diagnosis	II
Hypoglycemia	II
Hypogonadism	I
Hypoparathyroidism	I
Hypopituitarism	I
Hypothyroidism	I
Infertility	I
Menopause	I
Metabolic syndrome	I
Osteoporosis	I
Osteoporosis, secondary causes	II
Paget disease of the bone	I
Pancreatic islet cell tumors	III
Paraneoplastic syndromes	I
Pheochromocytoma	I
Pituitary adenoma	I
Pituitary region tumors	II
Polycystic ovary syndrome	I
Primary ovarian insufficiency	I
Prolactinoma	I
Pseudohermaphroditism	III
Sexual dysfunction	III
Sexual precocity, female breast development	III
Sexual precocity, female pubic hair development	III
Sexual precocity, male	III
Short stature	III
Syndrome of inappropriate antidiuresis	I
Thyroid nodule	I
Thyroid, painful, clinical algorithm	III
Thyroiditis	I
Thyromegaly	II

ENVIRONMENTAL MEDICINE	
Amebiasis	I
Babesiosis	I
Bite wounds	I
Bites and stings, arachnids	I
Bites and stings, insect	I
Bites, snake	I
Botulism	I
Burns	I
Contact dermatitis	I
Diarrhea, acute	III
Drowning	I
Ehrlichiosis	I
Electrical injury	I
Envenomation, marine	III
Food poisoning, bacterial	I
Frostbite	I
Giardiasis	I

Heat exhaustion and heat stroke I
High-altitude sickness I
Hypothermia I
Lyme disease I
Malaria I
Microsporidosis I
Mushroom poisoning I
Radiation exposure I
Rocky Mountain spotted fever I
Salmonellosis I
Shigellosis I
Southern tick-associated rash illness (STARI) I
Tapeworm infestation I
Vaccinations for international travel V
Zika virus I

GASTROENTEROLOGY
Abdominal compartment syndrome I
Abdominal pain, chronic lower II
Abdominal pain, nonsurgical causes II
Achalasia I
Acute colonoic pseudo-obstruction I
Acute liver failure I
Acute lower gastrointestinal bleeding I
Acute mesenteric ischemia I
Alcoholic hepatitis I
Anal abscess and fistula II
Anorectal fistula I
Anorectal stricture I
Anorexia II
Aphthous ulcers I
Appendicitis I
Ascariasis I
Ascites I
Autoimmune hepatitis I
Bacterial overgrowth, small intestine II
Barrett esophagus I
Bile duct, dilated II
Bleeding, gastrointestinal, algorithm III
Bleeding, rectal II
Bleeding, variceal III
Budd-Chiari syndrome I
Calcifications, liver on x-ray II
Calcifications, pancreas on x-ray II
Calcifications, spleen on x-ray II
Celiac disease I
Cholangiocarcinoma I
Cholangitis I
Cholecystitis I
Choledocholithiasis I
Cholelithiasis I
Chronic pancreatitis I
Cirrhosis I
Cirrhosis, primary biliary I
Cirrhotic cardiomyopathy I
Colic, acute abdominal II
Colorectal cancer I
Colostridium difficile infection I
Constipation, adult patient II
Constipation I, III
Crohn disease I
Cryptosporidium infection I
Delayed passage of meconium II
Diarrhea, acute III
Diarrhea, acute watery and bloody II
Diarrhea, chronic III
Diarrhea, chronic, in patients with HIV infection, algorithm III
Diarrhea, infectious II
Diarrhea, non-infectious II
Diarrhea, persistent I
Diverticular disease (diverticulosis, diverticulitis) I
Drug-induced liver injury I
Dyspepsia III
Dyspepsia, nonulcerative I
Dysphagia, oropharyngeal II
Echinococcosis I
Eosinophilic esophagitis I
Epigastric pain II
Esophageal tumors I
Esophageal varices I
Esophagitis II
Familial adenomatous polyps and Gardner syndrome I
Fetal alcohol spectrum disorder I
Food poisoning, bacterial I
Functional gallbladder disorder I
Gallbladder carcinoma I
Gastric cancer I
Gastric dilatation II
Gastric emptying, delayed II
Gastritis I
Gastroenteritis I
Gastroesophageal reflux disease I
Giardiasis I
Gilbert disease I
Glossitis I
Glossodynia II
Helicobacter pylori infection I
Hematemesis II
Hemochromatosis I
Hemoperitoneum II
Hemoptysis I
Hepatic encephalopathy I
Hepatitis A I
Hepatitis, acute II
Hepatitis B I
Hepatitis B prophylaxis V
Hepatitis C I
Hepatitis D I
Hepatitis E I
Hepatitis, viral III
Hepatomegaly, algorithm III
Hepatomegaly, by shape of liver II
Hepatopulmonary syndrome I
Hepatorenal syndrome I
Hookworm I
Hypergastrinemia II
Hypersplenism, associated conditions II
Hypoglycemia II
Incontinence, fecal II
Inguinal hernia I
Irritable bowel syndrome I
Ischemia, colon III
Ischemic colitis I
Ischemic hepatitis I
Jaundice, classification II
Jaundice in the adult patient I
Jaundice, neonatal II
Jaundice, neonatal, algorithm III
Lactose intolerance I
Large bowel obstruction I
Large bowel stricture II
Levator ani syndrome I
Liver abscess I
Liver disease, pregnancy II
Liver lesions, benign II
Liver transplantation I
Lynch syndrome I
Malabsorption II
Malabsorption algorithm III
Mallory-Weiss tear I
Microscopic colitis I
Nonalcoholic fatty liver disease I
Non-celiac disease gluten sensitivity I
Nutrition assessment and intervention in cancer patient III
Odynophagia II
Pancreas transplantation I
Pancreatic calcifications II
Pancreatic cancer (exocrine) I
Pancreatitis, drug-induced II
Peptic ulcer disease I
Perianal pain II
Peritonitis, secondary I
Peutz-Jeghers syndrome and other polyposis syndromes I
Pinworms I
Pneumatosis intestinalis in neonate and older child II
Portal hypertension I
Portal vein thrombosis I
Primary sclerosing cholangitis I
Rectal mass, palpable II
Retropharyngeal abscess I
Shigellosis I
Short bowel syndrome I
Small bowel masses II
Small bowel obstruction I
Small bowel intestinal bacterial overgrowth I
Small intestine ulceration II
Spontaneous bacterial peritonitis I
Subphrenic abscess I
Tapeworm infestation I
Toxic megacolon I
Traveler's diarrhea I
Ulcerative colitis I
Vitamin deficiency (hypovitaminosis) I

GYNECOLOGY AND OBSTETRICS
Abruptio placentae I
Abnormal uterine bleeding I
Acute fatty liver of pregnancy I
Acute pelvic pain in women I
Adnexal masses I
Amniotic fluid alpha-fetoprotein elevation II
Bartholin gland abscess I
Bleeding, early pregnancy III
Bleeding neonate III
Bleeding, vaginal III
Bone mineral density, increased II
Breast cancer I
Breastfeeding difficulties III
Breast, nipple discharge evaluation III
Breast, radiologic evaluation III
Breast, routine screen or palpable mass evaluation III
Cervical cancer I
Cervical dysplasia I
Cervicitis I
Chlamydia genital infections I
Condyloma acuminatum I
Contraception I
Cystitis, acute III
Delayed passage of meconium II
Dysmenorrhea I
Dyspareunia I
Dysuria and/or urethral/vaginal discharge III
Eclampsia I
Ectopic pregnancy I
Endometrial cancer I
Endometriosis I
Endometritis I
Erosions, genitalia II
Fallopian tube cancer I
Fertility preservation in women I
Fibrocystic breast disease I
Genital lesions or ulcers, algorithm III
Genitopelvic pain/penetration syndrome I
Gonococcal urethritis I
Gonorrhea I
Groin masses II
Heart failure, pregnancy II
Heavy menstrual bleeding I
Hereditary breast and ovarian cancer syndrome I
Herpes simplex I
Hot flashes I
Hyperemesis gravidarum I
Hypoactive sexual desire disorder I
Hypogonadism III
Immunizations during pregnancy V
Incontinence (urinary) I
Infertility I
Mastitis I
Mastodynia I
Meigs syndrome I
Menopause I
Molar pregnancy I
Nipple lesions II
Nongonococcal urethritis I
Ovarian cancer I
Ovarian neoplasm, benign I
Paget's disease of the breast I
Pelvic abscess I
Pelvic congestion syndrome I
Pelvic inflammatory disease I
Pelvic mass, algorithm III
Pelvic organ prolapse (uterine prolapse) I
Pelvic pain, causes in women II
Pelvic pain, reproductive-age woman III
Perirectal abscess I
Placenta previa I
Polycystic ovary syndrome I
Postpartum depression I
Postpartum hemorrhage I
Preeclampsia I
Premature rupture of membranes I
Premenstrual syndrome I
Preterm labor I
Primary ovarian insufficiency I
Pruritus, pregnant patient III
Pruritus vulvae I, II
Rh incompatibility I
Sexual assault I
Sexual dysfunction III
Sexual dysfunction in women I, II
Spontaneous abortion I
Syphilis I
Thrombocytopenia, in pregnancy II
Toxic shock syndrome I
Urinary tract infection I
Uterine fibroids I
Uterine malignancy I
Vaginal bleeding during pregnancy I
Vaginal discharge, algorithm III
Vaginal fistulas I
Vaginal cancer I
Vaginal prolapse III
Vaginitis, estrogen-deficient I
Vaginitis, fungal I
Vaginitis, prepubescent I
Vaginitis, *Trichomonas* I
Vaginosis, bacterial I

HEMATOLOGY/ONCOLOGY
Acute lymphoblastic leukemia I
Acute myeloid leukemia I
Anemia, algorithm III
Anemia, aplastic I, II
Anemia, aplastic due to drugs and chemicals II
Anemia, autoimmune hemolytic I
Anemia, hypochromic II
Anemia, inflammatory I
Anemia in newborn III
Anemia, iron deficiency I
Anemia, macrocytic III
Anemia, microcytic III
Anemia, pernicious I

Anemia with reticulocytosis III
Anorexia-cachexia syndrome associated with malignancy I
Antiphospholipid antibody syndrome I
Astrocytoma I
Atypical lymphocytosis, heterophil negative, infectious causes II
Basal cell carcinoma I
Bladder cancer I
Bleeding, congenital disorder III
Bleeding neonate III
Bleeding time (modified Ivy method) IV
Bone marrow failure syndromes, inherited II
Bone tumor, primary malignant I
Brain metastases I
Brain neoplasm I
Brain neoplasm, benign I
Brain neoplasm, glioblastoma I
Breast cancer I
Cancer of unknown primary site I
Cervical cancer I
Chemotherapy-induced nausea and vomiting I
Cholangiocarcinoma I
Chronic lymphocytic leukemia I
Chronic myeloid leukemia I
Chylothorax II
Cobalamin deficiency II
Colorectal cancer I
Conjunctival neoplasm II
Cryoglobulinemia I
Deep vein thrombosis I
Disseminated intravascular coagulation I
Endometrial cancer I
Erythrocytosis II
Erythrocytosis, acquired III
Esophageal tumors I
Eyelid neoplasm II
Fallopian tube cancer I
Fetal alcohol spectrum disorder I
Fever and neutropenia, pediatric patient III
Fever, non-infectious causes II
Folate deficiency II
Gallbladder carcinoma I
Gastric cancer I
Graft-versus-host disease (GVHD) I
Groin masses II
Head and neck squamous cell carcinoma I
Hemolysis, mechanical II
Hemolytic-uremic syndrome I
Hemophilia I
Hemoptysis I
Heparin-induced thrombocytopenia I
Hepatocellular carcinoma I
Hereditary breast and ovarian cancer syndrome I
Hodgkin lymphoma I
Hypercalcemia, malignancy-induced II
Hypercoagulable state I
Hypercoagulable state, associated disorders II
Hypersplenism I
Hypersplenism, associated conditions II
Immune thrombocytopenic purpura I
Intraocular neoplasm II
Iron overload II
Kaposi sarcoma I
Lead poisoning I
Liver lesions, benign II
Lung cancer, occupational causes II
Lung neoplasms, primary I
Lymphadenopathy, generalized, algorithm III
Lymphocytes IV
Lymphocytosis, atypical II
Macrothrombocytopenia, inherited II
Medical marijuana I
Meigs syndrome I
Melanoma I
Meningioma I
Mesothelioma, malignant I
Microangiopathic hemolytic anemia I
Monoclonal gammopathy of renal significance (MGRS) I
Monoclonal gammopathy of undetermined significance I
Monocytosis II
Mononucleosis, monospot negative II
Multiple endocrine neoplasia I
Multiple myeloma I
Myelodysplastic syndrome I
Nasopharyngeal carcinoma I
Neutropenia II
Neutropenia with decreased marrow reserve II
Neutrophilia II
Non-Hodgkin lymphoma I
Nutrition assessment and intervention in cancer patient III
Ovarian cancer I
Ovarian neoplasm, benign I
Paget's disease of the breast I
Pancreatic cancer (exocrine) I
Pancreatic islet cell tumors III
Pancytopenia II
Paraneoplastic neurologic syndromes II
Pericardial effusion, malignant III
Pheochromocytoma I
Pigmenturia II
Pituitary adenoma I
Pituitary region tumors II
Pleural effusion, malignant III
Pleural effusions, malignancy-associated II
Polycythemia II
Polycythemia, algorithm III
Polycythemia, relative versus absolute II
Polycythemia vera I
Postthrombotic syndrome I
Prolactinoma I
Prostate cancer I
Pulmonary infiltrates, immunocompromised host II
Purpura, nonpalpable II
Purpura, non-purpuric disorders simulating purpura II
Purpura, palpable II
Renal cell adenocarcinoma I
Reticulocyte count IV
Retinoblastoma I
Rh incompatibility I
Salivary gland neoplasms I
Sickle cell disease I
Spine tumor III
Splenomegaly, algorithm III
Splenomegaly and hepatomegaly II
Splenomegaly, children II
Squamous cell carcinoma I
Superior vena cava syndrome I
Testicular cancer I
Thalassemias I
Thrombocytopenia, differential diagnosis II
Thrombocytopenia, inherited disorders II
Thrombocytopenia, in pregnancy II
Thrombocytosis I
Thrombosis or thrombotic diathesis II
Thrombotic thrombocytopenic purpura I
Thyroid carcinoma I
Transfusion reaction, hemolytic I
Tumor lysis syndrome I
Tumor markers elevation II
Upper extremity deep vein thrombosis I
Uterine malignancy I
Vaginal cancer I
Von Willebrand disease I
Waldenström macroglobulinemia I

INFECTIOUS DISEASES

Acquired immunodeficiency syndrome I
Acute bronchitis I
Amebiasis I
Anaerobic infections I
Anal abscess and fistula II
Ascariasis I
Aspergillosis I
Aspiration, oral contents III
Aspiration pneumonia I
Atypical lymphocytosis, heterophil negative, infectious causes II
Babesiosis I
Bacterial overgrowth, small intestine II
Bacterial pneumonia I
Balanitis I
Bartholin gland abscess I
Bedbug bite I
Bite wounds I
Botulism I
Brain abscess I
Breast abscess I
Candidiasis, cutaneous I
Candidiasis, invasive I
Cat-scratch disease I
Cavernous sinus thrombosis I
Cellulitis I
Cervicitis I
Childhood and adolescent immunizations V
Chlamydia genital infections I
Cholangitis I
Cholecystitis I
Clostridium difficile infection I
Colorado tick fever I
Condyloma acuminatum I
Conjunctivitis I
Cryptococcosis I
Cryptosporidium infection I
Cysticercosis I
Cytomegalovirus infection I
Diarrhea, infectious II
Ear pain III
Echinococcosis I
Ehrlichiosis I
Empyema I
Encephalitis, acute viral I
Endocarditis, infective I
Endocarditis prophylaxis V
Endometritis I
Epididymitis I
Epidural abscess I
Epiglottitis I
Epstein-Barr virus infection I
Erysipelas I
Esophagitis II
Fever and infection in high-risk patient without obvious source III
Fever and neutropenia, pediatric patient III
Fever in the returning traveler I
Fever of undetermined origin I
Fifth disease (parvovirus infection) I
Folliculitis I
Food poisoning, bacterial I
Foot lesion, ulcerating II
Genital lesions or ulcers III
Giardiasis I
Gonococcal urethritis I
Granulomatous dermatitides II
Groin masses II
Hand-foot-mouth disease I
Helicobacter pylori infection I
Hepatitis A I
Hepatitis, acute II
Hepatitis B I
Hepatitis C I
Hepatitis D I
Hepatitis E I
Hepatitis, viral III
Herpes simplex I
Herpes simplex keratitis I
Herpes zoster I
HIV-associated cardiomyopathy I
Histoplasmosis I
HIV cognitive dysfunction I
HIV: Recommended immunization schedule for HIV-infected children V
Hookworm I
Human immunodeficiency virus I
Impetigo I
Immunization schedule, childhood, accelerated if necessary for travel V
Immunization schedule, childhood and adolescence V
Immunization schedule, contraindications and precautions V
Immunization schedule, HIV-infected children V
Immunizations for adults V
Immunizations during pregnancy V
Immunizations for immunocompromised infants and children V
Immunizing agents and immunization schedules for health-care workers V
Influenza I
Ischemic hepatitis I
Kaposi sarcoma I
Laryngitis I
Laryngotracheobronchitis I
Legionnaires' disease I
Lemierre syndrome I
Listeriosis I
Liver abscess I
Lung abscess I
Lyme disease I
Lymphangitis I
Lymphocytosis, atypical II
Malaria I
Mastoiditis I
Mediastinitis I
Mediastinitis, acute II
Meningitis, bacterial I
Meningitis, viral I
Meningitis, recurrent II
Mesenteric adenitis I
Methicillin resistant *Staphylococcus aureus* (MRSA) I
Microsporidiosis I
Middle East respiratory syndrome I
Molluscum contagiosum I
Mononucleosis I
Mononucleosis, monospot negative II
Mucormycosis I
Multidrug-resistant gram-negative rods (MRD-GNRs) I
Mumps I
Necrotizing fasciitis I
Necrotizing pneumonias II
Nongonococcal urethritis I
Orchitis I
Osteomyelitis I
Otitis externa I
Otitis media I
Paronychia I
Pediculosis I
Pelvic abscess I
Pelvic inflammatory disease I
Perirectal abscess I
Peritonitis, secondary I
Pertussis I

Pharyngitis/tonsillitis I
Pinworms I
Pneumonia, mycoplasma I
Pneumonia, *pnuemocystis jiroveci* I
Pneumonia, viral I
Prostatitis I
Pyelonephritis I
Reactive arthritis I
Renal abscess I
Rocky Mountain spotted fever I
Roseola I
Salmonellosis I
Scabies I
Scarlet fever I
Sepsis I
Septic arthritis I
Shigellosis I
Sialadenitis I
Sinusitis I
Sore throat II
Southern tick-associated rash illness (STARI) I
Spinal epidural abscess I
Spontaneous bacterial peritonitis I
Stomatitis I
Stye (hordeolum) I
Syphilis I
Tapeworm infestation I
Thrombophlebitis, superficial I
Tinea corporis I
Tinea cruris I
Tinea unguium I
Tinea versicolor I
Toxoplasmosis I
Tuberculosis, miliary I
Tuberculosis, pulmonary I
Urinary tract infection I
Urosepsis II
Vaccinations for international travel V
Vaccinations, recommendations for persons with medical conditions V
Vaginitis, fungal I
Vaginitis, *Trichomonas* I
Vancomycin resistant *Enterococcus* (VRE) I
Varicella I
Viral bronchiolitis I
Zika virus I

MISCELLANEOUS

Abdominal wall masses II
Anaphylaxis I
Anorexia II
Cyanosis II
Deep vein thrombosis I
Dehydration correction, pediatric patient III
Delayed passage of meconium II
Drowning I
Familial Mediterranean Fever I
Fever, non-infectious causes II
Food allergies I
Graft-versus-host disease (GVHD) I
Groin lump II
Hallucinogenic overdose I
Iliac fossa pain, left sided II
Iliac fossa pain, right sided II
Lactic acidosis I
Malignant hyperthermia I
Mediastinitis I
Mediastinal compartments, anatomy and pathology II
Medical marijuana I
Methanol and ethylene glycol poisoning I
Opioid overdose I
Opioid use disorder I
Paralytic shellfish poisoning I
Paraneoplastic syndromes I
Pleurisy I
Postthrombotic syndrome I
Sarcoma I
Shift work disorder I
Sore throat II
Statin-induced muscle syndromes I
Substance use disorder I
Synthetic cannabinoids I
Tracheobronchial narrowing on x-ray II
Upper extremity deep vein thrombosis I
Vitamin D deficiency I
Vitamin deficiency (hypovitaminosis) I

NEPHROLOGY

Acid-base homeostasis III
Acidosis, metabolic, algorithm III
Acute glomerulonephritis I
Acute kidney injury I
Acute tubular necrosis I
Acute urinary retention (AUR) I
Alkalosis, metabolic, algorithm III
Autosomal dominant polycystic kidney disease I
AV malformations, cerebral I
Calcium-alkali syndrome I
Calcium stones II
Cardiorenal syndrome I
Chronic kidney disease I
Contrast-associated acute kidney injury I
Dehydration correction, pediatric patient III
Edema, generalized, algorithm III
End-stage kidney disease I
Glomerulonephritis, rapidly progressive II
Glomerulopathies, thrombotic, microangiopathic II
Glomerulosclerosis, focal segmental II
Goodpasture syndrome I
Hematuria, in children II
Hemolytic-uremic syndrome I
Hepatorenal syndrome I
Hydronephrosis I
Hypercalcemia, algorithm IV
Hyperkalemia I
Hypermagnesemia, algorithm IV
Hypernatremia, algorithm IV
Hyperuricemia I
Hypocalcemia, laboratory differential diagnosis II
Hypokalemia, algorithm IV
Hypokalemia, differential diagnosis II
Hypokalemic periodic paralysis I
Hypomagnesemia I
Hypomagnesemia, algorithm IV
Hypomagnesemia, differential diagnosis II
Hyponatremia I, II
Hypoparathyroidism I
Hypophosphatemia, algorithm IV
IgA nephropathy I
Interstitial nephritis I
Kidney enlargement, unilateral II
Microscopic polyangiits I
Monoclonal gammopathy of renal significance (MGRS) I
Nephrocalcinosis II
Nephrotic syndrome I
Oliguria, algorithm III
Pigmenturia II
Pyelonephritis I
Relapsing polychondritis I
Renal abscess I
Renal artery stenosis I
Renal cell adenocarcinoma I
Renal cystic disorders II
Renal disease, ischemic management III
Renal failure, acute, pigment-induced II
Renal mass III
Renal parenchymal disease, chronic II
Renal tubular acidosis I
Renal vein thrombosis I
Rhabdomyolysis I
Scombroid poisoning I
Statin-induced muscle syndromes I
Tension-type headache I
Tumor lysis syndrome I
Uric acid stones II
Urinary retention II
Urine color abnormalities II
Urolithiasis I

NEUROLOGY

Absence seizures I
Acoustic neuroma I
Alzheimer's disease I
Amaurosis fugax I
Amblyopia I
Amyotrophic lateral sclerosis I
Anisocoria III
Anoxic brain injury I
Antibody-mediated autoimmune encephalitis I
Astrocytoma I
Ataxia, acute or recurrent II
Ataxia, cerebellar, adult onset II
Ataxia, cerebellar, children II
Ataxia, chronic or progressive II
Ataxia, progressive III
Autistic spectrum disorders I
AV malformations, cerebral I
Ballism II
Bell palsy I
Benign paroxysmal positional vertigo I
Blindness, monocular, transient II
Brain neoplasm I
Brain neoplasm, benign I
Brain neoplasm, glioblastoma I
Carotid artery stenosis I
Carpal tunnel syndrome I
Cerebral infarction secondary to inherited disorders II
Cerebrospinal fluid (CSF) IV
Charcot-Marie-Tooth disease I
Chronic inflammatory demyelinating polyneuropathy I
Chronic traumatic encephalopathy (CTE) I
Cluster headache I
Complex regional pain syndrome I
Concussion I
Convulsive disorder, pediatric age III
Daytime sleepiness II
Delirium I
Delirium, agitated II
Delirium, dialysis patient II
Dementia, algorithm III
Dementia with Lewy bodies I
Diabetic polyneuropathy I
Dilated pupil III
Diplopia, monocular II
Diplopia, vertical II
Dissociative disorders I
Dizziness II
Dystonia I
Elbow pain II
Encephalomyelitis, nonviral causes II
Encephalopathy I
Epidural abscess I
Epidural hematoma I
Esotropia II
Essential tremor I
Febrile seizures I
Focal seizures I
Footdrop II
Frontotemporal dementia I
Generalized tonic-clonic seizures I
Guillain-Barré syndrome I
Hallucinogenic overdose I
Headache, acute II
Headache, chronic II
Hearing loss, algorithm III
Hereditary neuropathy I
HIV cognitive dysfunction I
Horner syndrome I
Huntington chorea I
Hydrocephalus, normal pressure I
Inclusion body myositis I
Inflammatory myopathies I
Intracerebral hemorrhage, nonhypertensive causes II
Labyrinthitis I
Leg movement when standing, involuntary II
Leptomeningeal lesions II
Memory loss symptoms, elderly patients II
Meniere disease I
Meningioma I
Mental status changes and coma II
Migraine headache I
Mild cognitive impairment I
Mononeuropathies, isolated II
Motion sickness I
Multiple sclerosis I
Muscle disease II
Muscle weakness, algorithm III
Muscular dystrophy I
Myasthenia gravis I
Myelin disorders II
Myoclonus I
Myotonia I
Narcolepsy I
Neurocognitive disorders I
Neuromuscular junction dysfunction II
Neuronopathies, sensory (ganglionopathies) II
Neuropathic bladder II
Neuropathic pain I
Neuropathies, peripheral, asymmetrical proximal/distal II
Neuropathies with facial nerve involvement II
New onset seizures I
Nystagmus, monocular II
Opsoclonus II
Optic atrophy II
Optic neuritis I
Osteosclerosis, diffuse II
Paraneoplastic neurologic syndromes II
Paraparesis, acute or subacute II
Paraparesis, chronic progressive II
Parkinsonism-plus syndromes II
Parkinson disease I
Periodic limb movement disorder I
Polyneuropathies, demyelinating II
Polyneuropathies, distal, sensorimotor II
Postconcussive syndrome I
Postherpetic neuralgia I
Primary angiitis of the central nervous system I
Ramsay Hunt syndrome I
Restless legs syndrome I
Sciatica I
Seizures, mimics II
Shaken baby syndrome I
Smell disturbance II
Spasticity I
Spinal cord compression I
Spinal cord compression, epidural II
Spinal cord dysfunction, non-traumatic II
Spinal cord ischemic syndromes II
Spinal stenosis I
Status epilepticus I
Stroke, acute ischemic I

Associate Professor, Clinician Educator
Department of Psychiatry and Human Behavior
Department of Pediatrics
Warren Alpert Medical School of Brown University
Director, Child and Adolescent Psychiatry
Consultation-Liaison Service
Hasbro Children's Hospital
Providence, Rhode Island

Ali Kazim, MD
Chief of Psychiatry
Phoenix VA Health Care System
Clinical Professor of Psychiatry
University of Arizona Medical College
Phoenix, Arizona

Sudad Kazzaz, MD
Baylor College of Medicine
Houston, Texas

Sachin Kedar, MBBS, MD
Associate Professor
Neurological Sciences, Ophthalmology and Visual Sciences
University of Nebraska Medical School and Truhlsen Eye Institute
Omaha, Nebraska

A. Basit Khan, MD
Resident Physician
Neurosurgery
Baylor College of Medicine
Houston, Texas

Bilal Shahzad Khan, MD
Internal Medicine Fellow
Hypertension and Nephrology
Henry Ford Hospital
Detroit, Michigan

Rizwan Khan, MD
Cardiology Fellow
St. Elizabeth's Medical Center
Boston, Massachusetts

Sarthak Khare, MD
Medicine Resident and Cardiology Fellow
St. Elizabeth's Medical Center
Department of Medicine
Boston, Massachusetts

Hussain R. Khawaja, MD
Assistant Professor of Medicine, Clinician Educator
Warren Alpert Medical School of Brown University
Division of General Internal Medicine
Rhode Island Hospital
Providence, Rhode Island

Byung Kim, MD
Department of Hematology Oncology
Harold Alfond Center for Cancer Care
Augusta, Maine

Robert M. Kirchner, MD
Cardiology Fellow
Warren Alpert Medical School of Brown University
Providence, Rhode Island

Robert Kohn, MD
Department of Psychiatry and Human Behavior
Warren Alpert Medical School of Brown University
Providence, Rhode Island

Erna Milunka Kojic, MD
Professor
Division of Infectious Diseases
Icahn School of Medicine at Mount Sinai
New York, New York

Aravind Rao Kokkirala, MD, FACC
Warren Alpert Medical School of Brown University
Providence, Rhode Island

Yuval Konstantino, MD
Cardiology
Clinical Cardiac Electrophysiology
Soroka University Medical Center
Be'er-Sheva, Israel

Nelson Kopyt, DO
Chief of Nephrology
Lehigh Valley Hospital
Allentown, Pennsylvania
Clinical Professor of Medicine
Morsani College of Medicine
Tampa, Florida

Lindsay R. Kosinski, MD
Resident Physician
Warren Alpert Medical School of Brown University
Rhode Island Hospital
Providence, Rhode Island

Katherine Kostroun, MD
Baylor College of Medicine
Houston, Texas

Ioannis Koulouridis, MD, MS
Cardiology Fellow
St. Elizabeth's Medical Center
Boston, Massachusetts

Timothy R. Kreider, MD, PhD
Assistant Professor
Department of Psychiatry
Donald and Barbara Zucker School of Medicine at Hofstra/Northwell
Hempstead, New York

Prashanth Krishnamohan, MBBS, MD
Neurocritical Care
Stanford University
Palo Alto, California

Mohit Kukreja, MD
Clinical Fellow
Shoulder and Elbow Surgery
Warren Alpert Medical School of Brown University
Providence, Rhode Island

Lalathaksha Kumbar, MD
Senior Staff Physician
Division of Nephrology and Hypertension
Henry Ford Hospital
Detroit, Michigan

David I. Kurss, MD, FACOG, NCMP
Attending Physician, Clinical Assistant Professor
Obstetrics and Gynecology
State University of New York School of Medicine
Buffalo, New York

Sebastian G. Kurz, MD
Associate Professor

Preface

This book is intended to be a clear and concise reference for physicians and allied health professionals. Its user-friendly format is designed to provide a fast and efficient way to identify important clinical information and to offer practical guidance in patient management. The book is divided into five sections and an appendix, each with emphasis on clinical information.

The tremendous success of the previous editions and the enthusiastic comments from numerous colleagues have brought about several positive changes over time. Each section has been significantly expanded from prior editions, bringing the total number of medical topics covered in this book to more than 1200. Hundreds of new illustrations, tables, and boxes have been added to this edition to enhance recollection of clinically important facts. The expedited claims submission and reimbursement ICD-10CM codes are included in all topics.

Section I describes in detail 988 medical disorders and diseases—including 25 new topics this edition—arranged alphabetically and presented in outline format for ease of retrieval. Topics with an accompanying algorithm are identified with an ALG icon. Similarly, those topics with an accompanying online Patient Teaching Guide (PTG) are identified with a PTG symbol. Throughout the text, key quick-access information is consistently highlighted, with clinical photographs to further illustrate selected medical conditions, and relevant ICD-10CM codes listed. Most references focus on current peer-reviewed journal articles rather than outdated textbooks and old review articles.

Topics in **Section I** use the following structured approach:

1. Basic Information (Definition, Synonyms, ICD-10CM Codes, Epidemiology & Demographics, Physical Findings & Clinical Presentation, Etiology)
2. Diagnosis (Differential Diagnosis, Workup, Laboratory Tests, Imaging Studies)
3. Treatment (Nonpharmacologic Therapy, Acute General Rx, Chronic Rx, Disposition, Referral)
4. Pearls & Considerations (Comments, Suggested Readings)

Section II includes the differential diagnosis, etiology, and classification of signs and symptoms. This practical section allows the user investigating a physical complaint or abnormal laboratory value to follow a "workup" leading to a diagnosis. The physician can then easily look up the presumptive diagnosis in Section I for information specific to that illness.

Section III includes more than 150 clinical algorithms to guide and expedite the patient's workup and therapy. For the 2021 edition, we have continued to update algorithms and colorize online versions for improved readability. Physicians describe this section as particularly valuable in today's managed-care environment.

Section IV includes normal laboratory values and interpretation of results of commonly ordered laboratory tests. By providing interpretation of abnormal results, this section facilitates the diagnosis of medical disorders and further adds to the comprehensive "one-stop" nature of our text. New illustrations and tables have been added for this edition.

Section V focuses on preventive medicine. Information here includes screening recommendations for major diseases and disorders, patient counseling, and immunization and chemoprophylaxis recommendations.

The **Appendix** is divided into nine major sections. Appendix I contains extensive information on complementary and alternative medicine (CAM), now expanded to include Common Herbs in Integrated Medicine, as well as Herbal Activities Against Pain and Chronic Diseases. With this material, we aim to lessen the current scarcity of exposure of allopathic and osteopathic physicians to the diversity of CAM therapies. Appendix II focuses on nutrition, with an emphasis on dietary supplements, vitamins, and minerals. Appendix III deals with diagnosis and treatment of acute poisoning. Appendix IV is a guide on impairment and disability evaluation. Appendix V focuses on the protection of travelers. Appendix VI addresses Physician Quality Reporting System (PQRS) measures. Appendix VII—available in the online version of *Ferri's Clinical Advisor*—is a repository of practical patient instruction sheets, organized alphabetically and covers the majority of topics in this book. These guides can be easily customized and printed and serve as valuable tools for improving physician-patient communication, patient satisfaction, and ultimately quality of care. Appendix VIII and IX are both new to this edition and offer guidance related to palliative care and preoperative evaluation, respectively.

I believe that we have produced a state-of-the-art information system with significant differences from existing texts. The information offered in all five sections and patient education guides could be sold separately based on their content, yet are available under a single cover, offering the reader tremendous value. I hope that the *Clinical Advisor*'s user-friendly approach, numerous unique features, and yearly updates will make this book a valuable medical reference, not only to primary care physicians but also to physicians in other specialties, medical students, and allied health professionals.

BASIC INFORMATION

DEFINITION

An abdominal aortic aneurysm (AAA) is a focal full-thickness dilation of the abdominal aortic artery to at least 1.5 times the diameter measured at the level of the renal arteries, or exceeding the normal diameter of the abdominal aorta by 50%. The normal diameter at the renal arteries is 2 cm (range 1.4 to 3.0 cm), and a diameter 3 cm or larger is generally considered aneurysmal.

ICD-10CM CODES

I71.4 Abdominal aortic aneurysm, without rupture
I71.3 Abdominal aortic aneurysm, ruptured

EPIDEMIOLOGY & DEMOGRAPHICS

- Approximately 15,000 deaths/yr in the United States are attributed to AAA.
- AAA is predominantly a disease of older adults, affecting men more than women (4:1).
- The prevalence rate ranges from 4% to 9% in men in developed countries.
- Clinically important AAAs ≥4 cm are present in 1% of men between age 55 and 64; and the prevalence rate increases by 2% to 4% per decade thereafter.
- The peak incidence is among men approximately 70 yr old.
- The frequency is much higher in smokers than in nonsmokers (8:1); and the risk decreases with smoking cessation.
- Risk factors for AAA are similar to those for other atherosclerotic cardiovascular diseases. They include age, Caucasian race, smoking, male gender, family history, hypertension, hyperlipidemia, peripheral vascular disease, and aneurysm of other large vessels.
- AAA is two to four times more common in first-degree male relatives of known AAA patients.
- A decreased risk of AAA is associated with female gender, non-Caucasian race, and diabetes.
- Rupture of the AAA occurs in 1% to 3% of men age 65 or older.
  1. Rupture is the 10th leading cause of death in men older than age 55.
  2. Mortality from rupture is 70% to 95%.
  3. Risk factors for rupture include cardiac or renal transplants, severe obstructive lung disease, uncontrolled blood pressure, female sex, and ongoing tobacco use.
- A recent decline in incidence and prevalence of AAA and related mortality has been attributed to reductions in tobacco use. However, AAA are at least 9× more common than thoracic aortic aneurysms.

ETIOLOGY

- Exact etiology is unknown and is likely multifactorial.
  1. Degenerative:
     a. Alterations in vascular wall biology leading to a loss of vascular structural proteins and wall strength.
     b. The most common association is atherosclerosis. It is uncertain whether atherosclerosis causes or results from AAAs.
     c. Tobacco use: >90% of people who develop an AAA have smoked at some point in their lives.
  2. Inherited: Familial clusters are common. High familial prevalence rate is notable in male individuals. The nature of the genetic disorder is unclear but may be linked to alpha-1-antitrypsin deficiency or X-linked mutation. Connective tissue disorders, such as Marfan syndrome and Ehlers-Danlos syndrome, have also been strongly associated with AAA.
  3. Inflammatory: AAA is a progressive inflammatory disease of the artery walls. Activated B lymphocytes promote AAA by producing immunoglobulins, cytokines, and matrix metalloproteinases (MMPs), resulting in the activation of macrophages, mast cells (MCs), and complement pathways that lead to the degradation of collagen and matrix proteins and to aortic wall remodeling.
  4. Infection, mycotic: Syphilis, *Salmonella.*

NATURAL HISTORY

- AAAs tend to develop in the infrarenal aorta and to expand, on average, at a rate of 0.2 to 0.5 cm per yr.
- The risk of aneurysmal rupture is largely influenced by aneurysm size, rate of expansion, and sex. Other factors associated with increased risk for rupture include continued smoking, uncontrolled hypertension, and increased wall stress.
- Higher tension in the abdominal aorta (together with histopathologic changes such as accumulation of foam cells, cholesterol crystals, and matrix metalloproteinases) renders the abdominal aortic wall more susceptible to dilation and subsequent rupture.
- The 5-yr rupture rate of asymptomatic AAAs is 25% to 40% for aneurysms >5.0 cm in diameter, 1% to 7% for AAAs 4.0 to 5.0 cm, and nearly 0% for AAAs <4.0 cm. The likelihood that an aneurysm will rupture is increased in aneurysms with a diameter >5.5 cm; this size also demonstrates a faster rate of expansion (>0.5 cm over 6 months) and is more likely to be found in those who continue to smoke and in females.
- Mortality rate after rupture can be as high as 90% because most patients do not reach the hospital in time for surgical repair. Of those who reach the hospital, the mortality rate is still 50%, compared with the 1% to 4% mortality rate for elective repair of a nonruptured AAA.

SCREENING AND MONITORING

- The USPSTF recommends one-time screening for AAA by ultrasonography in men ages 65 to 75 who have a history of smoking, and in those 60 yr of age or older with a history of AAA in a parent or sibling. These populations have been shown to have a higher prevalence of AAA, and selectively screening this group has been shown to decrease AAA-specific mortality.
- The USPSTF has found little benefit in repeat screening in men with a negative ultrasound and has determined that men over the age of 75 are unlikely to benefit from screening. It was also concluded that the current evidence is insufficient to assess the balance of the harms and benefits of screening for AAA in women ages 65 to 75 who have ever smoked.
- The Society for Vascular Surgery Guidelines recommend monitoring by ultrasound or CT scan should be performed every 6 months for patients with AAAs measuring 5.0 to 5.4 cm in diameter, every 12 months for AAAs measuring 4.0 to 4.9 cm in diameter, and every 3 yr for AAAs 3.0 to 3.9 cm in diameter.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most aneurysms are asymptomatic and incidentally discovered on imaging studies; however, symptomatic aneurysms are at an increased risk for rupture.
- Physical examination has a sensitivity of 76% for detecting AAAs >5 cm and only 29% for AAAs 3.0 to 3.9 cm. The accuracy of the physical examination is markedly diminished by obese body habitus.
- Symptomatic patients may present with abdominal, back, flank, or groin pain.
- A pulsatile epigastric mass that may or may not be tender may be present
- Abdominal bruits can be present in case of renal or visceral arterial stenosis.
- Common iliac arteries can be aneurysmal and palpable in the lower abdominal quadrants. In addition, prominent femoral and popliteal pulses warrant an abdominal ultrasound and lower extremity ultrasound.
- Early satiety, nausea, and vomiting may be caused by compression of adjacent bowel.
- Venous thrombosis or insufficiency may occur from iliocaval venous compression.
- Thromboembolization can cause lower extremity pain and discoloration.
- Ureteral obstruction and hydronephrosis can cause flank and groin pain and lead to obstructive renal failure.
- Rupture classically presents as a triad of abdominal or back pain, hypotension, and a pulsatile abdominal mass in 50% of patients.
- Acute blood loss may lead to myocardial infarction; arteriovenous fistulas may present as heart failure; aortoenteric fistulas may present as hematemesis or melena associated with abdominal and back pain.

(From Townsend CM et al [eds]: *Sabiston textbook of surgery*, ed 17, Philadelphia, 2004, Saunders.)

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Almost 75% of patients with AAA are asymptomatic, and the condition is discovered on routine examination or serendipitously when ordering studies for other symptoms. Diagnosis of AAA should be considered in the differential of the following symptoms: abdominal pain, back pain, and/or pulsatile abdominal mass. The differential diagnosis includes peptic ulcer disease, mesenteric ischemia, renal calculi, pyelonephritis, and diverticulitis.

LABORATORY TESTS

Not routinely indicated. For suspected infected or inflammatory aneurysms, WBC, ESR/CRP, and blood cultures can be considered. An elevated D-dimer may indicate a thrombus within the aneurysm. Fig. 1 describes an algorithm for the diagnosis and treatment of abdominal aortic aneurysms.

IMAGING STUDIES

- Abdominal ultrasound (Fig. 2) has nearly 100% sensitivity and specificity in identifying an aneurysm and estimating the size to within 0.3 to 0.4 cm. It is not accurate in estimating the extension to the renal arteries or the iliac arteries.
- Computed tomography (CT) (Fig. 3) scan is recommended for preoperative aneurysm imaging and estimates the size of the AAA to within 0.3 mm. There are no false-negative results, and the scan can identify extension to renal vessels with more precision than ultrasound. It is the imaging modality of choice for symptomatic AAA. Intravenous contrast is not required to establish a diagnosis of ruptured AAA. CT can also detect the integrity of the wall (Fig. 4) and exclude rupture.

- Magnetic resonance angiography (MRA) may also be used and is at least as accurate as CT.
- Plain radiographs may show the outline of an aneurysm in calcified aortas. This is an insensitive test for diagnosing AAA.
- Diagnostic aortography has essentially been replaced by other noninvasive imaging modalities such as CT or MR angiography. Intraoperative angiography is still used for determining treatment options and post-procedure efficacy (Fig. 5).
- Endovascular aneurysm repair (EVAR) needs close and lifelong imaging surveillance of the aneurysm site for the timely detection of possible complications, including endoleaks, graft migration, fractures, graft infection, and enlargement of aneurysm sac size with eventual rupture. The rate of complications after EVAR is approximately 30% with 2% to 3% of these requiring reintervention. Contrast-enhanced computed tomography (CTA) is considered the gold standard in EVAR follow-up (Fig. 6), but it is accompanied with radiation burden and renal injury because of the use of contrast media. In the past 2 decades, several studies have shown the role of contrast-enhanced ultrasonography (CEUS) in post-EVAR surveillance, with very good diagnostic performance, absence of renal impairment, and no radiation, accompanied by low costs, in comparison with CTA. In numerous prospective studies and meta-analyses, the detection and characterization of endoleaks with CEUS is comparable to that of CTA imaging.

FIG. 4 Aneurysm of the abdominal aorta. A large aortic aneurysm is evident. The aorta exceeds 5 cm in diameter. A large amount of thrombus *(T)* partially surrounds the contrast-enhanced patent lumen *(L)*. Note the atherosclerotic calcification (*arrowhead*) in the wall of the aneurysm.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Despite lack of data substantiating reduction in expansion rate through treatment of cardiac risk factors, nonpharmacologic treatment continues to focus on risk factor modification (most importantly smoking cessation, diet, and exercise). Of note, moderate exercise does not increase the rate of aneurysm expansion or the risk of rupture.
- Serial studies have shown that expansion rates are faster in current smokers than in former smokers. Patients with known AAA or a family history of aneurysms should be advised to stop smoking and be offered smoking cessation interventions.
- Definitive treatment depends on the size of the aneurysm (see "Chronic Rx").

ACUTE GENERAL Rx

- Acute symptomatic or ruptured AAA can be treated with open surgical repair (OSR) or EVAR. The choice is determined by anatomic considerations, operative risks, and availability of regular patient follow-up for EVAR.

FIG. 6 Completion digital subtraction angiogram following endovascular aneurysm repair. (From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology*, ed 8, Philadelphia, 2017, Elsevier.)

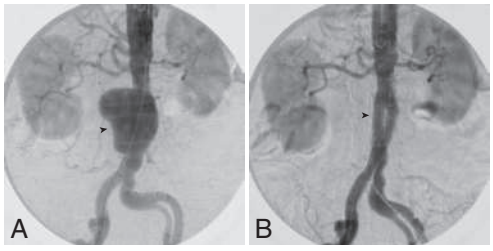

FIG. 5 A, Conventional catheter angiography with bilateral marked catheters in place demonstrates a large, lobulated, infrarenal aortic aneurysm (*arrowhead*) with a 4-cm proximal neck suitable for endovascular repair. **B,** An image after endovascular repair demonstrates complete exclusion of the aneurysm (*arrowhead*) with no endoleak and preservation of the renal and hypogastric arteries. (From Soto JA, Lucey BC: *Emergency radiology: the requisites*, ed 2, Philadelphia, 2017, Elsevier.)

- Emergent open repair has been the traditional method of treatment. However, multiple trials have shown lower mortality and shorter hospital stay with EVAR. More centers are increasingly using endovascular repair for patients who fit certain anatomic and physiologic criteria.
- A recent Cochrane meta-analysis involving pooled data for four trials comparing EVAR versus open repair for ruptured abdominal aortic aneurysm failed to show a difference in 30-day mortality between EVAR versus open repair. There was a higher incidence of reintervention for patients undergoing EVAR, although interventions to deal with procedural complications were generally less invasive and involved catheter-based approaches.
- The major limitations for EVAR include anatomical issues such as tortuosity or small caliber iliac arteries and inability to follow up patients to exclude late failure of stent-grafts and development of endoleaks.

CHRONIC Rx

- Blood pressure and fasting lipids should be monitored and controlled as recommended for patients with atherosclerotic disease. Statins are associated with decreased mortality after successful AAA repair, and are recommended for those with known AAA to reduce the progression of atherosclerosis and overall cardiovascular risk.
- The most commonly used predictor of rupture is the maximum diameter of the AAA.
- Long-term beta-blocker therapy has slowed the rate of aortic dilation and decreased the incidence of aortic complications in patients with Marfan syndrome. Several studies have also suggested that beta-blocker therapy may reduce the rate of expansion and risk of rupture; however, conclusive evidence is lacking.
- A recent multicenter study of 5362 patients with AAA found no significant association between AAA progression and the use of statins, beta-blockers, angiotensin-converting enzyme inhibitors, or angiotensin II receptor blockers.
- Antibiotics such as doxycycline and roxithromycin have been shown to limit the expansion of small AAAs.
- AAA repair to eliminate the risk for rupture should be performed for patients with infrarenal or juxtarenal AAA of approximately 5.5 cm or larger in diameter. Repair in females can be considered at diameters larger than 5 cm. Additionally, AAAs with a rate of enlargement greater than 0.5 cm over 6 months should be considered for repair. All patients who are symptomatic should undergo repair, regardless of size. Timing of repair in symptomatic unruptured AAA is still under debate.
- There is no clear advantage to early repair (open or endovascular) for small asymptomatic AAAs (less than 5.5 cm).
- Percutaneous, endovascular, stent-anchored grafts placed with the patient under local anesthesia have provided an alternative approach for patients with favorable anatomy.

In patients who have undergone EVAR, long-term surveillance is required to assess for an endoleak, stent migration, change in aneurysm size, and need for re-intervention.

- EVAR with proximally fenestrated grafts is an alternative to open repair in the management of juxtarenal aortic aneurysms and short-neck abdominal aortic aneurysms (the "neck" is the distance from the lowest main renal artery to the beginning of the aneurysm). Contemporary literature shows it is a safe and efficacious treatment, particularly for those deemed surgically high risk.
- Randomized trials and meta-analyses comparing EVAR with OSR have shown that EVAR is associated with lower 30-day mortality and MI rates, shorter hospital stays, and better health-related quality of life up to 12 months postoperatively. However, EVAR also has increased rates of graft-related complications and is more costly. Additionally, a recent meta-analysis showed that 5 to 9 yr postoperatively, EVAR is associated with higher all-cause mortality, reintervention, and secondary rupture rates compared with OSR. Over >10 yr, EVAR is associated with higher reintervention and secondary rupture rates.
- Based on current data, less than 2% of endovascular repairs require open conversion, and approximately half of all early endoleaks resolve spontaneously within a period of 30 days.
- Open surgical repair of AAAs is the preferred approach for patients with a long life expectancy.
- Endovascular AAA repair is the preferred approach for most patients with a reasonable life expectancy and suitable anatomy.
- For patients with limited life expectancy, elective AAA repair is not recommended.
- Surveillance for endovascular AAA repair has typically involved use of periodic CT scans, but abdominal ultrasound is gaining widespread adoption for postprocedure monitoring. Surveillance is recommended to occur 1 and 12 months postoperatively and then annually thereafter.
- In high-risk patients undergoing AAA repair, specifically those with coronary artery disease or those with more than one clinical risk factor based on the American Heart Association (AHA) guidelines, preoperative administration of beta-blockers titrated to a goal heart rate of 60 have been shown to decrease incidence of death from cardiac causes or nonfatal myocardial infarctions. Beta-blockers initiated within 24 hours of the procedure have not shown an advantage; however beta-blockers the patient is already taking should be continued.
- Patients with chronic obstructive pulmonary disease (COPD) are at higher risk for major clinical complications, particularly if the COPD is suboptimally managed or if it is present in conjunction with cardiac or renal disease. Smoking cessation for 2 months before surgery has also been shown to decrease pulmonary morbidity.
- Renal dysfunction is a strong predictor of mortality, showing up to as high as 41% mortality in those with impaired renal function compared with 6% in those without renal dysfunction.

REFERRAL

- Vascular surgical referral should be made in asymptomatic patients with AAAs that are approximately 4.5 cm.
- In patients with an expansion rate of 0.5 cm over 6 months, it is reasonable to offer repair, although small studies have shown that using expansion as a criterion for surgical referral is of unclear benefit.
- It is important to optimize any comorbid conditions before surgical referral.

PEARLS & CONSIDERATIONS

- Repairing asymptomatic AAAs smaller than 5.5 cm has not been shown to improve survival because the risk of rupture is lower than the risk of surgery.
- The results from multiple trials to date demonstrate no advantage to immediate repair for small AAA (4.0 to 5.5 cm), regardless of whether open or endovascular repair is used and, at least for open repair, regardless of patient age and AAA diameter. Thus, neither immediate open nor immediate endovascular repair of small AAAs is supported by the currently available evidence.
- Five-yr survival remains poor after elective AAA repair despite advances in short-term outcomes and is associated with AAA diameter and patient age at the time of surgery. Research in this field should attempt to improve the life expectancy of patients with repaired AAA and to optimize patient selection.

COMMENTS

- Most AAAs are infrarenal. This is thought to be due in part to decreased lamellar structural proteins in the vascular wall below the renal arteries leading to decreased vascular wall strength.
- Surgical risk is increased in patients with coexisting coronary artery disease, pulmonary disease, or chronic renal failure. Evaluation for ischemia and aggressive perioperative hemodynamic monitoring help identify high-risk patients and decrease postoperative complications.
- It is estimated that AAAs at <5 cm expand at a rate of 0.2 to 0.3 cm/yr, and AAAs at >5 cm expand at a rate of 0.3 to 0.5 cm/yr.

Abdominal Compartment Syndrome

BASIC INFORMATION

DEFINITION

Abdominal compartment syndrome (ACS) is defined by the presence of organ dysfunction as a result of increased abdominal pressure or intraabdominal hypertension. The increased abdominal pressure reduces blood flow to internal organs, which can lead to multiple system failure and death if not promptly recognized and treated.

ICD-10CM CODE
M79.A3 Nontraumatic compartment syndrome of abdomen

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Very few studies have examined the incidence of ACS outside of trauma patients, among whom it ranges from 1% to 14%, depending on the population and type of trauma studied. The incidence is the highest among critically ill patients.

RISK FACTORS: The biggest risk factor for developing ACS is critical illness stemming from a wide array of medical and surgical conditions (Table E1). In particular, any illness that requires a patient to undergo large volume intravenous fluid resuscitation can be associated with ACS; the third-spacing of fluid can lead to increased intraabdominal pressures secondary to tissue edema. Due to large volume fluid resuscitation, ACS is commonly seen in severe burns, trauma, post-surgical patients, and sepsis. Other conditions associated with ACS include intraabdominal and retroperitoneal pathologies such as significant bowel distention, liver transplantation, massive ascites, ruptured abdominal aortic aneurysm with resulting hemoperitoneum, pancreatitis, and abdominal surgery (Table E2).

TABLE E1 Causes of Intraabdominal Hypertension and Abdominal Compartment Syndrome

Increased Abdominal Contents	Decreased Abdominal Volume
Ascites	Reduction of large long-standing hernia
Hemoperitoneum	Direct closure of large, long-standing abdominal wall defect
Abdominal packs	
Peritonitis	
Retroperitoneal edema (pancreatitis)	Retroperitoneal edema (pancreatitis)
Large pelvic, retroperitoneal hematoma	Large pelvic, retroperitoneal hematoma
Intestinal obstruction	
Ileus	
Gastric distention (esophageal ventilation)	
Abdominal aortic aneurysm	
Severe constipation	
Large abdominal tumor (chronic)	
Morbid obesity (chronic)	
Pregnancy (chronic)	

From Vincent JL et al: *Textbook of critical care*, ed 6, Philadelphia, 2011, Saunders.

TABLE E2 Independent Predictors of Postinjury Primary and Secondary Abdominal Compartment Syndrome

	ED Model Independent Predictors	ICU Model Independent Predictors
Primary ACS	To OR <75 min Crystalloids ≥3 L	Temp ≤34° C $GAPco_2$ ≥16 Hb ≤8/dl BD ≥12 mEq/L
Secondary ACS	Crystalloids ≥3 L No urgent surgery PRBC ≥3 units	$GAPco_2$ ≥16 Crystalloids ≥7.5 L UO ≤150 ml

ACS, Abdominal compartment syndrome; *BD*, arterial base deficit; *CI*, confidence interval; *ED*, emergency department; *$GAPco_2$*, carbon dioxide gap; *Hb*, hemoglobin concentration; *ICU*, intensive care unit; *OR*, operating room; *PRBC*, packed red blood cells; *Temp*, temperature; *UO*, urine output.
From Vincent JL et al: *Textbook of critical care*, ed 6, Philadelphia, 2011, Saunders.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The most striking physical examination finding is often massive abdominal distention.
- Difficulty maintaining respiratory support and decreased urine output are also typical hallmarks.
- Other common findings include those associated with poor perfusion states and hypotension such as skin mottling, cool extremities, and obtundation. Patients will often have abdominal tenderness, signs of volume overload such as edema and elevated jugular venous pressures, and may present with acute respiratory decompensation.

ETIOLOGY

ACS can affect nearly every organ system. High intraabdominal pressures are associated with increased intracranial pressures, which can precipitate cerebral ischemia. Elevated abdominal pressures can cause cardiac compression by decreasing ventricular compliance and contractility as well as impairing inferior vena cava venous return, leading to increased central venous and pulmonary pressures. Due to elevation of the diaphragm, patients will often have reduced tidal volumes and lower chest wall compliance, which can lead to atelectasis, pneumonia, hypoxemia, and hypercarbia. Mechanically ventilated patients will also require increased airway pressures that can lead to barotrauma. In addition, renal vein compression and renal artery vasoconstriction lead to decreased urine output. Reduced mesenteric blood flow can lead to intestinal ischemia and lactic acidosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Mesenteric ischemia
- Sepsis
- Shock
- Acute kidney injury
- Adult respiratory distress syndrome

WORKUP

Measurement of intraabdominal pressure is required to make a definitive diagnosis. Bladder pressure is the most common surrogate used to estimate intraabdominal pressures and is measured using a bladder catheter. The most accurate measurements can be obtained with the patient in supine position at end expiration in the absence of abdominal contractions. The threshold abdominal pressure often set for research purposes to define ACS is >20 mm Hg, but patients may have ACS with pressures of >10 mm Hg and above. Oliguria tends to develop at a pressure of 15 mm Hg, and anuria occurs around 30 mm Hg. Intraabdominal pressures can also be estimated using intragastric, intracolonic, and inferior vena cava approaches (Table E3).

TABLE E3 Classification of Abdominal Compartment Syndrome

Basis of Classification	Subcategories
Time frame	Acute
	Chronic
Relation to peritoneal cavity	Primary
	Secondary
Etiology	Trauma
	Burn
	Postoperative
	Pancreatitis
	Bowel obstruction
	Ileus
	Abdominal aortic aneurysm
	Oncologic
	Gynecologic

From Vincent JL et al: *Textbook of critical care*, ed 6, Philadelphia, 2011, Saunders.

LABORATORY TESTS

Laboratory testing is generally not helpful for the diagnosis of ACS. The presence of lactic acidosis suggests bowel ischemia, which portends a poorer prognosis.

IMAGING STUDIES

Imaging alone has no diagnostic value in ACS, but chest imaging can be helpful to evaluate for diaphragmatic elevation and evidence of pulmonary complications (atelectasis, volume overload, pneumonia, etc.). Abdominal computed tomography imaging will sometimes show renal displacement, inferior vena cava compression, abdominal wall thickening, or bowel injury related to ischemia but should not be relied on to make the diagnosis of ACS.

Rx TREATMENT

Supportive care and, when appropriate, surgical abdominal decompression are the mainstays of ACS treatment.

NONPHARMACOLOGIC THERAPY

- Supportive care, often with hemodynamic and ventilatory support, as well as techniques to improve abdominal wall compliance, are the foundations of ACS management.
- Severe burns to the abdomen leading to ACS will require surgical escharotomy to improve abdominal wall compliance.
- Patients with tense ascites leading to ACS will require large volume paracentesis to decrease intraabdominal pressures.
- Patients should be positioned supine if possible as any elevation of the head will increase abdominal pressures.
- Rectal and nasogastric decompression is required if ACS is due to massive bowel distention.

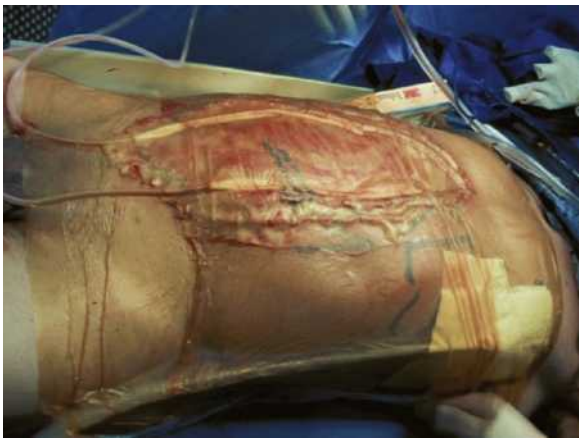

FIG. E1 Open abdomen management of abdominal compartment syndrome. The sterile saline bag was sewn to the skin edges. Closed suction drains were placed to limit fluid accumulation, and occlusive dressing was applied to cover the abdominal wall. (Courtesy Brian J. Kimbrell, MD, In Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.)

FIG. E2 Open abdomen management of abdominal compartment syndrome using a vacuum-assisted closure (VAC) system. The bowel is covered with omentum if possible. Nonadherent dressing is layered under a VAC sponge, or a smaller pore sponge is used against the viscera. Negative pressure is applied to the wound closure to drain fluid, facilitate closure, and prevent evisceration. (Courtesy Brian J. Kimbrell, MD, In Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.)

- Proper sedation and pain control can decrease intraabdominal pressures, and some patients may require ventilatory support and chemical paralysis to maximize abdominal wall relaxation.
- Mechanical ventilation is often difficult due to the high pressures that need to be generated to overcome the increased intraabdominal pressures. Often a combination of low tidal volumes, permissive hypercapnia, chemical paralysis, and high positive end-expiratory pressure are required to ensure adequate ventilatory support.
- Although there is little data to support its use, the administration of colloid may be superior to crystalloid if the patient requires further volume resuscitation. The administration of intravenous fluids will transiently increase renal blood flow, leading to increased urine output and improved organ perfusion and cardiac output. Pressors may also have a role to maintain perfusion pressures, but all of these measures are temporizing and supportive until definitive action through surgical decompression is performed.
- The threshold to perform surgical decompression for ACS has yet to be established; however, data suggest that early decompression prior to the development of ACS may lead to better outcomes. If appropriate, consensus dictates that surgical decompression should be performed on all patients with intraabdominal pressure >25 mm Hg; however, some surgeons are more aggressive and will consider decompression with pressures of 15 to 25 mm Hg in the right clinical setting. Surgical decompression (Fig. E1, Fig. E2) by incising vertically through the linea alba can be performed at the bedside in emergent situations and most surgeons will then keep the abdomen open through the use of a temporary abdominal closure device that retains heat/fluid and prevents evisceration until the time is appropriate to attempt to close the abdomen again.

ACUTE GENERAL Rx

There are no direct pharmacologic agents that treat ACS other than pressors, sedatives, pain medications, and paralytics required for

supportive care as described above. Despite underlying volume overload, diuretics have no role in therapy. Definitive management is surgical decompression.

DISPOSITION

Close inpatient monitoring, preferably in an intensive care setting, is indicated as mortality can be extremely high (>40%) with ACS.

REFERRAL

Patients with ACS often require admission to an intensive care setting with surgical consultation in case decompression is required.

PEARLS & CONSIDERATIONS

COMMENTS

- ACS is seen in critically ill medical and surgical patients, and its diagnosis requires both the presence of intraabdominal hypertension and end organ dysfunction.
- ACS is truly a systemic illness that can lead to multisystem organ failure and is therefore associated with a high mortality.
- Definitive diagnosis of ACS requires measurement of intraabdominal pressure, which is most frequently estimated using bladder pressure as a surrogate.
- Supportive care, including hemodynamic support with colloids, pressors, and ventilatory support, is often required, but surgical decompression is the only definitive treatment.
- Surgical decompression is indicated for intraabdominal pressures >25 mm Hg; however, precise thresholds have not been established, and earlier decompression may lead to better outcomes.

BASIC INFORMATION

DEFINITION

Abnormal uterine bleeding (AUB) describes uterine bleeding that is abnormal in regularity, quantity, frequency, or duration, in the nonpregnant person. Historically, AUB was described as in Table 1. The term "dysfunctional uterine bleeding" was applied when no clear etiology could be identified. These terms have fallen out of favor. In 2011, the FIGO Working Group on Menstrual Disorders released a classification system intended to simplify these definitions. It is known by the acronym PALM-COEIN, described later. Today, AUB is described according to these criteria.

A normal menstrual cycle is typically described as lasting 21 to 35 days with 5 days of bleeding per cycle. Total blood loss for normal menses is thought to be less than 80 ml.

SYNONYMS

Abnormal uterine bleeding (AUB)
Dysfunctional uterine bleeding

ICD-10CM CODES

N92.5 Other specified irregular menstruation
N92.0 Excessive and frequent menstruation with regular cycle
N91.5 Oligomenorrhea, unspecified
N92.1 Excessive and frequent menstruation with irregular cycle
N94.6 Dysmenorrhea, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Most cases of AUB result from uterine pathology (the PALM portion of the acronym).
- Up to 20% of women presenting with heavy menstrual bleeding will be found to have a coagulopathy.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical findings depend on the etiology. For example, an enlarged/irregular uterine contour may suggest fibroids, or a polyp may be seen on the cervix during a speculum examination.
- The clinical presentation is also variable. Although many patients complain of the abnormality of their cycles, some will present with symptoms of anemia, with AUB being elicited only with a careful history. Patients may note recent weight gain or on examination, may have other findings (as noted later) suggestive of the etiology for their bleeding.
- Thorough physical and pelvic examination to exclude the other causes of abnormal bleeding:
  1. Includes thyroid, breast, liver (e.g., presence or absence of ecchymotic lesions)
  2. Patient habitus: Obese and hirsute (polycystic ovarian disease) or thin (think eating disorders or excessive exercise)
  3. Presence or absence of vulvar, vaginal, or cervical lesions, uterine (fibroid) or ovarian tumors, urethral caruncles or diverticula, hemorrhoids, anal fissures, colorectal lesions
  4. Bimanual pelvic examination: Normal-sized or enlarged uterus, regular or irregular contour

ETIOLOGY

- Table 2 describes many of the various causes of AUB. The causes of AUB in the fourth and fifth decade are summarized in Table 3.
- Endocrinopathies, including hyperprolactinemia and thyroid disorders, may also contribute to heavy or irregular menstrual bleeding.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- PALM–COEIN:
  1. Polyps (AUB-P)
  2. Adenomyosis (AUB-A)
  3. Leiomyoma (AUB-L)
  4. Malignancy/hyperplasia (AUB-M)
  5. Coagulopathy (AUB-C; most commonly von Willebrand disease)
  6. Ovulatory dysfunction (AUB-O; most commonly polycystic ovarian syndrome)
  7. Endometrial (AUB-E)
  8. Iatrogenic (AUB-I; e.g., anticoagulants, hormonal contraception, and some herbal remedies)
  9. Not yet classified (AUB-N)
- Anatomic nonuterine causes:
  1. Cervical neoplasia, cervicitis
  2. Vaginal neoplasia, adhesions, trauma, foreign body, atrophic vaginitis, infections, condyloma
  3. Vulvar trauma, infections, neoplasia, condyloma, dystrophy, varices
  4. Urinary tract: Urethral caruncle, diverticulum, hematuria
  5. Gastrointestinal tract: Hemorrhoids, anal fissure, colorectal lesions
- Systemic diseases/effects:
  1. Exogenous hormone intake: Hormone replacement therapy

TABLE 1 Definitions of Abnormal Uterine Bleeding

Term	Description
Oligomenorrhea	Bleeding at intervals greater than 35 days
Polymenorrhea	Bleeding at intervals less than 21 days
Hypermenorrhea (menorrhagia)	Excessive flow or bleeding with normal intervals
Metrorrhagia	Bleeding between menses
Menometrorrhagia	Excessive flow or duration with periods and between periods
Withdrawal bleeding	Bleeding after the withdrawal of hormones

Crum CP et al: *Diagnostic gynecologic and obstetric pathology,* ed 3, Philadelphia, 2018, Elsevier.

TABLE 2 Causes of Abnormal Uterine Bleeding

Age (Years)	Causes (In Order of Decreasing Frequency)
Prepubertal	Precocious puberty (hypothalamic, pituitary, ovarian)
Adolescence	• Disorders in the hypothalamic-pituitary axis (transient) • Disorders in folliculogenesis (transient) • Sexually transmitted infections, undiscovered pregnancy • Hematologic disorders (von Willebrand factors VII, XI)
Third and fourth decades	• Oral contraceptive pill-related • Postpregnancy • Benign organic lesions (polyps, leiomyomata, endometritis) • Anovulatory cycle
Fifth decade	• Anovulatory or altered cycle • Benign organic lesions (polyps, adenomyosis, leiomyomata, or endometritis) • Neoplasia
Sixth decade	• Hormone replacement therapy • Benign organic lesions (polyps, adenomyosis, leiomyomata, endometritis) • Atrophy • Neoplasia

Crum CP et al: *Diagnostic gynecologic and obstetric pathology,* ed 3, Philadelphia, 2018, Elsevier.

TABLE 3 Causes of Abnormal Uterine Bleeding in the Fourth and Fifth Decades

Cause	Differential Diagnosis
Anovulation	• Endometrial polyp • Basalis
Endometrial polyp	• Basalis/lower uterine segment • Tangentially sectioned functionalis • Atypical polypoid adenomyoma • Adenomyomatous polyp • Intraendometrial leiomyoma • Adenosarcoma
Chronic endometritis	• Late menstrual endometrium • Postpartum/postabortal endometrium • Cervical tissue (plasma cells) • Menstrual endometrium • Lymphoproliferative disorder
Submucosal leiomyoma	• Progestin/tamoxifen therapy • Endometrial polyp • Stromal neoplasm

Crum CP et al: *Diagnostic gynecologic and obstetric pathology,* ed 3, Philadelphia, 2018, Elsevier.

2. Medications
3. Coagulopathies: Von Willebrand disease, thrombocytopenia, hepatic failure
4. Endocrinopathies: Thyroid disorder, hyperprolactinemia, diabetes mellitus
5. Renal diseases: Generally causing acquired coagulopathy
6. Impaired nutritional status: Anorexia/bulimia

- Section II describes a differential diagnosis of vaginal bleeding abnormalities.

WORKUP

- Detailed history:
  1. Age of menarche
  2. Prior menstrual characteristics (newly abnormal or always so)
  3. Severity of bleeding
  4. Surgical and medical history suggestive of other causes/contributors
- Thorough physical examination, including a pelvic examination (bimanual and speculum) to exclude causes mentioned above
- Includes thyroid, breast, liver (e.g., presence or absence of goiter, galactorrhea, or ecchymotic lesions)
  1. Patient habitus: Obese and hirsute (polycystic ovarian disease) or thin (think eating disorders or excessive exercise)
  2. Presence or absence of vulvar, vaginal, or cervical lesions, uterine (fibroid) or ovarian tumors, urethral caruncles or diverticula, hemorrhoids, anal fissures, or colorectal lesions

LABORATORY TESTS (AS INDICATED BY HISTORY AND PHYSICAL)

- Complete blood count with platelets to evaluate for possible iron-deficiency anemia or thrombocytopenia
- Prothrombin/INR and partial thromboplastin (or PFA-100 assay) if coagulopathy is suspected
- von Willebrand panel, particularly in women with heavy bleeding since menarche if initial testing suggests coagulopathy
- Serum or urine human chorionic gonadotropin
- Chemistry profile, including liver function tests
- Thyroid profile
- Pap smear if not up to date
- Cultures for gonorrhea and chlamydia
- Serum gonadotropins and prolactin
- Serum androgens
- Endometrial biopsy or dilation and curettage, especially in patients over 45, or in younger patients with a long-standing history of anovulatory bleeding with fewer than three menstrual cycles per yr or with a high risk of endometrial neoplasia with prolonged unopposed estrogen exposure
- Stool testing for occult blood
- Urinalysis for hematuria

IMAGING STUDIES

- Pelvic ultrasound, including measurement of endometrial thickness in the postmenopausal woman and assessment of myometrial or endometrial defects. This is considered first line.
- Fluid contrast ultrasound (also called saline sonogram, sonohysterogram, saline infusion sonogram, etc.) may be indicated if the endometrium appears thickened or irregular. It distends the uterine cavity so that "filling defects" of the endometrium can be assessed for possible endometrial polyp, uterine fibroid, or neoplasm.
- Hysteroscopy may be performed to assess intracavitary fibroids or polyps.
- Magnetic resonance imaging may help better characterize large fibroids or uterine pathology but is rarely needed.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Increase iron intake in the form of pills and a diet rich in iron to combat anemia.
- Initiate lifestyle changes, including weight loss, exercise, and low-carb diet, if indicated.

ACUTE GENERAL Rx

- Progestins:
  1. Medroxyprogesterone acetate (oral), 10 to 20 mg daily for 15 days
  2. Megestrol acetate, 40 to 120 mg daily in divided doses for 15 days
  3. Oral contraceptives: One tablet tid for 5 to 7 days; patient should then continue on oral contraceptives daily
- Estrogens:
  1. Conjugated estrogen 25 mg IV q4h until bleeding is under control (in cases of severe or life-threatening bleeding); maximum 24 hr
  2. For prolonged bleeding that is not life threatening: Premarin 1.25 mg (Estrace 2 mg) q4h for 24 hr, followed by Provera to bring on withdrawal bleeding; then sequential regimen of estrogen and progestin (Premarin 1.25 mg qd for 24 days, Provera 10 mg for last 10 days) or oral contraceptives

CHRONIC Rx

- Progestins:
  1. Medroxyprogesterone acetate 10 mg daily for 12 days, then cyclically to induce monthly withdrawal bleeding
  2. Norethindrone 2.5 to 10 mg qd for 12 days each mo or 0.35 mg daily (marketed as the "mini-pill")
  3. Depo-Provera 150 mg IM every 3 mo
  4. Oral contraceptives, one tablet qd either cyclically or continuously using only active pills
  5. Levonorgestrel-releasing intrauterine device (Mirena has an FDA indication for heavy menstrual bleeding)
- Letrozole or clomiphene citrate: Not typically a treatment for abnormal bleeding but may help patients with anovulatory bleeding who want to become pregnant. Progesterone withdrawal may be counterproductive in patients wishing to start an ovulation induction regimen. Pregnancy rates are lower when patients undergo withdrawal compared to when random ovulation induction start is used. Letrozole is superior to clomiphene citrate in ovulation induction in women with PCOS. Human menopausal gonadotropin (HMG) can be used for women who do not ovulate with oral agents or who have hypothalamic dysfunction.
- Others:
  1. Anti-prostaglandins (ibuprofen or naproxen sodium can reduce bleeding by 40%).
  2. Danazol (rarely used due to side-effect profile).
  3. Gonadotropin-releasing hormone (GnRH) analogues; often used to reduce bleeding and ameliorate anemia and in preparation for a surgical procedure.
  4. Tranexamic acid (Lysteda) is an antifibrinolytic agent FDA approved for cyclic heavy menstrual bleeding. Dosage in normal renal function is 3900 mg daily (650 mg tablets, 2 tablets tid) for up to five days during menses.
  5. Endometrial tamponade with Foley catheter.
- Surgical treatment:
  1. Dilation and curettage and operative hysteroscopy
  2. Endometrial ablation
  3. Uterine artery embolization
  4. Hysterectomy

DISPOSITION

Cyclical treatment on birth control pills or Provera for several cycles, then discontinue pill and watch patient for onset of regular menses. If the patient does not want to conceive, continued cycle management with a hormonal contraceptive is commonly used.

REFERRAL

To gynecologist in case of failure of treatment

PEARLS & CONSIDERATIONS

- Always get a pregnancy test.
- If a young patient presents at menarche with bleeding severe enough to warrant emergency evaluation, there is a higher risk of a bleeding disorder, such as von Willebrand disease.
- Endometrial sampling is indicated in patients over 45 yr of age with new AUB.

BASIC INFORMATION

DEFINITION

Abruptio placentae is the separation of placenta from the uterine wall before delivery of the fetus. The condition occurs in approximately 1% of pregnancies. There are three classes of abruption (Fig. 1) based on maternal and fetal status, including an assessment of uterine contractions, quantity of bleeding, fetal heart rate monitoring, and abnormal coagulation studies (fibrinogen, prothrombin time, partial thromboplastin time).

- Grade I: Mild vaginal bleeding, uterine irritability, stable vital signs, reassuring fetal heart rate, normal coagulation profile (fibrinogen 450 mg/dl). Approximately half of abruptions are grade I.
- Grade II: Moderate vaginal bleeding, hypertonic uterine contractions, orthostatic blood pressure measurements, unfavorable fetal status, fibrinogen 150 to 250 mg. Approximately a quarter of abruptions are grade II.
- Grade III: Severe bleeding (may be concealed), hypertonic uterine contractions, overt signs of hypovolemic shock, fetal death, thrombocytopenia, fibrinogen <150 mg/dl. Approximately a quarter of abruptions are grade III.

SYNONYM

Premature separation of placenta

ICD-10CM CODES

O45.8X9	Other premature separation of placenta, unspecified trimester
O45.8X1	Other premature separation of placenta, first trimester
O45.8X2	Other premature separation of placenta, second trimester
O45.8X3	Other premature separation of placenta, third trimester
O45.91	Premature separation of placenta, unspecified, first trimester
O45.92	Premature separation of placenta, unspecified, second trimester
O45.93	Premature separation of placenta, unspecified, third trimester

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 9.6 per 1000 births; 80% occur before the onset of labor.

RISK FACTORS: Hypertension (greatest association), trauma, polyhydramnios, multifetal gestation, smoking, use of cocaine, chorioamnionitis, preterm premature rupture of membranes. Table 1 summarizes placental abruption risk factors.

RECURRENCE RATE: 5% to 17%, some studies showing a 5- to 10-fold increase in risk; with two prior episodes, 25%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Triad of uterine bleeding (concealed or per vagina), hypertonic uterine contractions or signs of preterm labor, and evidence of fetal compromise exists.
- More than 80% of cases have external bleeding; 20% of cases have no bleeding but have indirect evidence of abruption, such as failed tocolysis for preterm labor.
- Tetanic uterine contractions are found in only 17%.

ETIOLOGY

- Primary etiology: Unknown
- Hypertension: Found in 40% to 50% of grade III abruptions
- Rapid decompression of uterine cavity, as can occur in polyhydramnios or multifetal gestation
- Blunt external trauma (motor vehicle accident, spousal abuse)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Placenta previa
- Cervical or vaginal trauma
- Labor
- Cervical cancer
- Rupture of membranes
- The differential diagnosis of vaginal bleeding in pregnancy is described in Section III

WORKUP

- Placental abruption is primarily a clinical diagnosis that is supported by laboratory, radiographic (Fig. 2), and pathologic studies.
- Initial assessment should evaluate for the source of bleeding, ruling out placenta previa that may contraindicate any type of vaginal examination (e.g., pelvic speculum examination).
- Continuous fetal heart monitoring is indicated for all viable gestations (60% incidence of fetal distress in labor); may show early signs of maternal hypovolemia (late decelerations or fetal tachycardia) before overt maternal vital sign changes.
- Actual amount of blood loss is often greater than initially perceived because of the possibility of concealed retroplacental bleeding and apparent "normal" vital signs. The relative hypervolemia of pregnancy initially protects the patient until late in the course of bleeding, when abrupt and sudden cardiovascular collapse can occur.

LABORATORY TESTS

- Baseline serum hemoglobin helps quantify blood loss and establish baseline values for serial comparisons during expectant management.
- Coagulation profile: Platelets, fibrinogen, prothrombin, and partial thromboplastin time. Diffuse intravascular coagulation can develop with severe abruption. If fibrinogen is <150 mg/dl, estimated blood loss is approximately 2000 ml; if fibrinogen is <100 mg/dl, consider fresh frozen plasma to prevent further bleeding.
- Type and antibody screen is important to identify Rh-negative patients who need Rh immune globulin.

IMAGING STUDIES

Ultrasound should include fetal presentation and status, amniotic fluid volume, placental location, as well as any evidence of hematoma (retroplacental, subchorionic, or preplacental) (Fig. E3).

TREATMENT

ACUTE GENERAL Rx

- Stabilization of the mother is the first priority.
- Treatment depends on gestational age of the fetus, severity of the abruption, and maternal status.
- Initial assessment for signs of maternal hemodynamic compromise or hemorrhagic shock; large-bore intravenous access, with crystalloid fluid resuscitation using a replacement of 3 ml lactated Ringer solution for every 1 ml estimated blood loss.

TABLE 1 Placental Abruption Risk Factors

Increasing parity or maternal age
Cigarette smoking
Cocaine abuse
Trauma
Maternal hypertension
Preterm premature rupture of membranes
Rapid uterine decompression associated with multiple gestation and polyhydramnios
Inherited or acquired thrombophilia
Uterine malformations or fibroids
Placental abnormalities or ischemia
Prior abruption

From Gabbe SG: *Obstetrics*, ed 6, Philadelphia, 2012, Saunders.

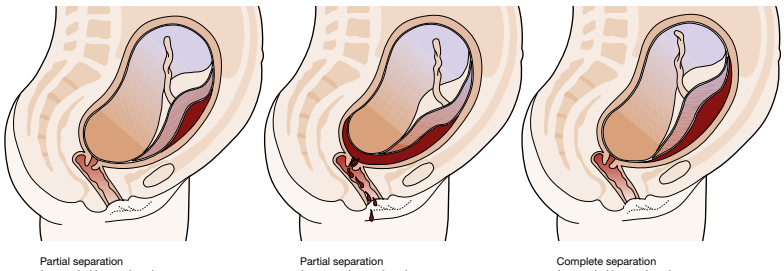

FIG. 1 Classification of placental abruption. (From Magowan BA: *Clinical obstetrics & gynecology,* ed 4, 2019, Elsevier.)

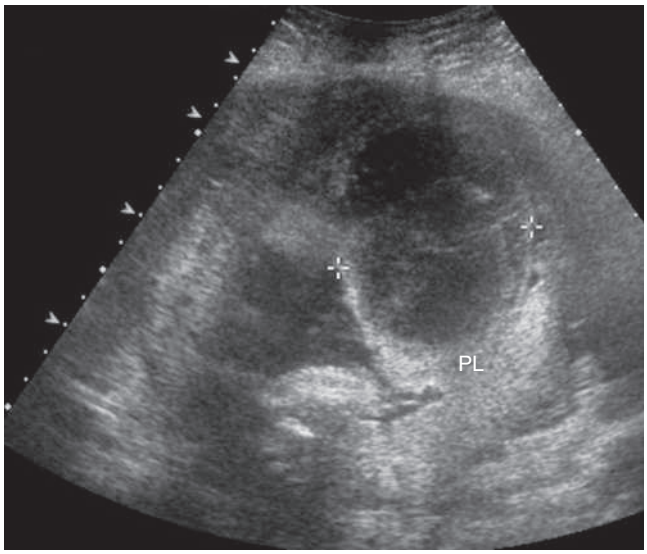

FIG. 2 Placental abruption. Transabdominal sonogram of the placenta *(PL)* with a hematoma *(calipers)* lifting the placenta away from the uterine wall. (From Rumack CM et al [eds]: *Diagnostic ultrasound*, ed 4, Philadelphia, 2011, Mosby.)

- Indwelling Foley catheter to monitor urine output and maternal volume status, with a goal of 30 ml/hr urine output.
- Assess fetal status and gestational age by sonogram and continuous fetal heart rate monitoring.
- Because of the unpredictable nature of abruptions, cross-matched blood should be made available during the initial resuscitation period.

CHRONIC Rx

- In the term fetus, delivery is indicated.
- In the preterm fetus, consider betamethasone 12.5 mg IM q24h for two doses and then delivery, depending on the severity of the abruption and the likelihood of fetal complications from preterm birth.
- Cesarean section should be reserved for cases of fetal distress or for standard obstetric indications. While cesarean delivery may be needed to stabilize the fetal and/or maternal status, the mother's coagulation status may complicate the procedure and availability of blood products may be critical.
- In cases of maternal stability and fetal prematurity, expectant management can occur in the setting of close follow-up, including regular evaluation of fetal growth and reassuring antenatal testing.

DISPOSITION

Because of the unpredictable nature of abruptions, expectant management should occur only under controlled circumstances.

REFERRAL

Abruptio placentae places mother and fetus in a high-risk situation and should be managed by a qualified obstetrician in a facility with capability for neonatal and maternal resuscitation, for supporting a preterm infant if delivery is indicated at an early gestational age, and for performing emergency cesarean sections.

BASIC INFORMATION

DEFINITION

Absence seizures are a type of generalized seizure characterized by brief episodes of staring with impairment of consciousness (absence). They usually last no more than 20 to 30 sec. The onset and the end of the seizures are sudden. Usually the patients are not aware of them and resume the activity they were performing before the seizure. The electroencephalogram signature of absence seizures consists of a generalized 3-Hz spike and slow wave discharges.

SYNONYMS

Childhood absence epilepsy
Seizures, absence

ICD-10CM CODE

G40.309 Generalized idiopathic epilepsy and epileptic syndromes, not intractable, without status epilepticus

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 1 to 10 cases per 100,000 population
PEAK INCIDENCE: 6 to 7 yr
PREVALENCE: Represents up to 18% of all pediatric epilepsy syndromes
PREDOMINANT SEX AND AGE: More common in girls than in boys, absences typically begin between 4 and 8 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with absence seizures usually have normal physical and neurologic examinations.
- During the seizures, the patients are unresponsive and can have motor phenomena (automatisms, eye blinks, mouth and hand movements).
- Absence seizures are not associated with postictal confusion.
- They may be triggered by hyperventilation associated with activity.
- Tonic clonic seizures are not usually a feature of this syndrome. If the patient also experiences tonic clonic seizures, other etiologies should be investigated, such as juvenile absence epilepsy, juvenile myoclonic epilepsy, complex partial seizures, etc.

ETIOLOGY

Genetic

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Juvenile absence epilepsy
- Juvenile myoclonic epilepsy
- Complex partial seizures
- Focal seizures with altered consciousness (Table E1)
- Nonepileptic spells comprised of staring

WORKUP

- EEG with hyperventilation and photic stimulation is crucial in the diagnosis.
- Ambulatory EEG and video EEG are recommended for patients with diagnostic uncertainty.

LABORATORY TESTS

No specific studies needed

IMAGING STUDIES

- MRI of the brain should be performed in all epilepsy patients, especially if the EEG does not show the typical characteristic of absence seizures (3-Hz spike and slow wave discharges).
- CT scans of the head should be avoided in children due to unnecessary exposure to radiation and low yield of the test except when MRI cannot be obtained.

TREATMENT

The medication of choice based on the best current evidence available is ethosuximide, followed by valproic acid and lamotrigine.

NONPHARMACOLOGIC THERAPY

Not applicable

GENERAL Rx

- Ethosuximide: Initial dose: 10 mg/kg/day; then after 7 days, 20 mg/kg
- Divalproex sodium (Depakote): Initial dose: 5 to 10 mg/kg/day (divided bid), maximum dose: 60 mg/kg/day
- Lamotrigine (Lamictal): Dose for patients on no other antiepileptic drugs. Wk 1 and 2: 0.3 mg/kg/day. Wk 3 and 4: 0.6 mg/kg/day. Wk 5 onward: Increase every 1 to 2 wk by 0.6 mg/kg/day. Maintenance: 4.5 to 7.5 mg/kg/day. Warning: Should be used with caution due to the potential for toxicity and Stevens-Johnson syndrome. Patients on other antiepileptic drugs can also have severe adverse reactions (e.g., valproate can cause increased levels of lamotrigine, and lamotrigine must be titrated much more slowly in patients on valproate therapy).

CHRONIC Rx

- Children with recurrent seizures require chronic treatment.
- If children are seizure-free for a period of 1 to 2 yr, a trial on no medications should be considered; children typically outgrow childhood absence seizures.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Not applicable

DISPOSITION

- Response to treatment is excellent.
- Absence seizures tend to remit in teenage yr.
- Epilepsy can be considered as resolved once 10 yr have elapsed since the last event, including 5 yr free from medications.

REFERRAL

Patients with epilepsy and seizures should be referred for a consultation by a neurologist, preferably one specializing in epilepsy.

PEARLS & CONSIDERATIONS

COMMENTS

- Absence seizures can be present in other epilepsy syndromes.
- Valproate should be avoided in girls and women with childbearing potential due to the risk of teratogenicity.
- Carbamazepine and phenytoin should be avoided in the treatment of absence seizures, since these medications may worsen seizures and could provoke absence status epilepticus.
- All women of childbearing age taking antiepileptic drugs should take folic acid supplementation (1 to 4 mg/day) for the prevention of neural tube defects.

PREVENTION

Sleep deprivation and alcohol consumption should be avoided.

PATIENT & FAMILY EDUCATION

- Patients with ongoing seizures are forbidden to drive; check state regulations and laws regarding driving and epilepsy.

Absence Seizures

TABLE E1 Comparison of Focal Seizures with Altered Consciousness and Absence Seizures

Feature	Focal Seizure with Altered Consciousness	Absence
Aura	Often	Never
Consciousness	Impaired	Lost at onset
Movements	Usually simple, repetitive but may include complex	Blinking and facial and finger automatism activity
Postictal behavior	Amnesia, confusion, and tendency to sleep	No abnormality, except amnesia for ictus
Frequency	1-2 per week	Several daily
Duration	2-3 minutes	1-10 seconds
Precipitants		Hyperventilation, photic stimulation
EEG	Spikes and poly spike and waves, usually over one or both temporal regions	Generalized 3-Hz spike-and-wave complexes
Treatment	Carbamazepine, phenytoin	Ethosuximide, valproate

Acetaminophen Poisoning ALG PTG

BASIC INFORMATION

DEFINITION

Acetaminophen (APAP) poisoning is a disorder caused by excessive intake of APAP and is manifested by jaundice, nausea, vomiting, abdominal discomfort, and potential death from hepatic necrosis if not treated appropriately.

SYNONYM

Paracetamol poisoning

ICD-10CM CODES

T39.1	Poisoning by 4-aminophenol derivatives, accidental
X60	Intentional self-poisoning by 4-aminophenol derivatives

EPIDEMIOLOGY & DEMOGRAPHICS

- APAP is one of the most widely prescribed antipyretics and analgesics in the U.S. Potentially toxic ingestions, both intentional and unintentional, exceed 100,000 cases annually in the U.S.
- APAP toxicity is the number one cause of acute liver failure in the U.S.
- Death rate is approximately one in 1000 persons. Nearly 50% of exposures occur in children ≤6 yr.
- Hepatic necrosis is most likely to occur in people who (1) are chronically malnourished, (2) regularly abuse alcohol, (3) have chronic liver disease, and (4) use other potentially hepatotoxic medications.
- Combination opioid and acetaminophen medications are an important source of APAP toxicity.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The physical examination may vary depending on the amount of time since ingestion.
- Phase I (0 to 24 hr): Initial symptoms may be mild or absent and may consist of anorexia, diaphoresis, malaise, nausea, vomiting, lethargy, and a subclinical rise in transaminase levels.
- Phase II (24 to 72 hr): Right upper quadrant pain, vomiting, somnolence, tachycardia, jaundice, hypotension, and continued increase in transaminases.
- Phase III (72 to 96 hr): Hepatic necrosis with abdominal pain, jaundice, hepatic encephalopathy, coagulopathy, hypoglycemia, renal failure, fatality from multi-organ failure.
- Phase IV (4 days to 2 wk): Complete resolution of symptoms and resolution of organ failure.
- Table E1 summarizes the four phases/stages of acetaminophen poisoning.

ETIOLOGY

- The amount of APAP necessary for hepatic toxicity varies with the patient's body size and hepatic function. It is recommended that APAP intake should not exceed 3 to 4 g for adults and 90 mg/kg in children within a 24-hr period.
- A standardized nomogram is used to determine potential hepatic toxicity by knowing the APAP plasma level and the number of hours after ingestion. See the APAP ingestion algorithm (Fig. E1).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Liver disease from alcohol abuse or viral hepatitis
- Ingestion of other hepatotoxic substances
- Bacterial/viral gastroenteritis

WORKUP

Initial workup is aimed at confirming APAP overdose with plasma APAP level and assessment of hepatic damage. A careful history should elicit the time of APAP ingestion, amount, preparation (e.g., extended release), and possible coingestants (see "Laboratory Tests").

LABORATORY TESTS

- Initial laboratory evaluation should include an initial plasma APAP level with a second level drawn approximately 4 hr after the initial ingestion. Subsequent levels can be obtained every 2 to 4 hr until the levels stabilize or decline. Levels starting from 4 hr postingestion should be plotted on the Rumack-Matthew nomogram (see acetaminophen ingestion algorithm [Fig. E1] to calculate potential hepatic toxicity). The nomogram cannot be used with patients who present >24 hr after ingestion, took extended-release preparations, had chronic ingestions, or when the time of ingestion is unknown.
- Transaminases (aminotransferase [AST], alanine aminotransferase [ALT]), serum glucose, bilirubin level, lipase level, prothrombin time (INR), blood urea nitrogen, creatinine, EKG, and urinalysis should be initially obtained on all patients.
- Serum and urine toxicology screens for other potential toxic substances (e.g., salicylate level, ethanol level, urine drugs of abuse screening) is also recommended on admission. Screening for infectious hepatitis should also be considered.
- Urine for β-hCG should be obtained from all women of childbearing age.

TREATMENT

NONPHARMACOLOGIC THERAPY

Consultation with a Poison Control Center is recommended for patients who have ingested a large amount of APAP and/or other toxic substances. A single toxic dose of APAP usually exceeds 7 g or 150 mg/kg in adults.

ACUTE GENERAL Rx

- Hepatotoxicity is defined as any increase in ALT or aspartate AST >1000 IU/L, and hepatic failure manifests as hepatotoxicity with hepatic encephalopathy. For those who cannot be risk stratified using the nomogram, the American College of Emergency Physicians recommends that *N*-acetylcysteine be administered without delay to those >12 yr and >8 hr after ingestion at presentation. This would include anyone with an ingestion of APAP over many days with an APAP level <20 μg/ml (with or without ALT elevation) or anyone with undetectable APAP levels with an elevated ALT and a history of excessive APAP intake.
- Administer activated charcoal 1g/kg PO if the patient is seen within 1 hr of ingestion or the clinician suspects polysubstance ingestion that delays gastric emptying.
- Determine serum acetaminophen levels 4 hr after ingestion; if in the toxic range based on the Rumack-Matthew nomogram, start *N*-acetylcysteine (NAC) either IV (Acetadote) or PO (Mucomyst). Acetylcysteine IV loading dose is 150 mg/kg ×1 diluted in 200 ml D5W over 15 to 60 min. Maintenance dose is 50 mg/kg diluted in 500 ml D5W over 4 hr, followed by 100 mg/kg diluted in 1000 ml D5W over 16 hr. The dose does not require adjustment for renal or hepatic impairment or for dialysis. Total administration time is 21 hours.
- Oral administration is 140 mg/kg PO as a loading dose, followed after 4 hr by 70 mg/kg PO q4h for a total of 18 doses. *N*-acetylcysteine therapy should be started within 24 hr of APAP overdose. Total administration time is 72 hours.
- Advantages of IV administration include more reliable absorption, fewer doses, and shorter duration of treatment. Disadvantages include cost and lower hepatic concentrations from first-pass flow as compared to oral acetylcysteine.
- Monitor APAP level; use Rumack-Matthew nomogram to trend hepatic toxicity. Repeat AST/ALT and APAP levels after 12 to 14 hr of IV acetylcysteine infusion and continue infusion longer than 16 hr if transaminases are elevated, if APAP concentration is still measurable, or if coagulopathy exists (INR >1.5 to 2.0). Patients with severe, irreversible liver failure may need to continue NAC until liver transplantation is available.
- Provide adequate IV hydration (e.g., D_5½NS at 150 ml/hr).
- Patients on IV *N*-acetylcysteine with liver failure require frequent monitoring of vital signs, oxygen saturation by pulse oximetry, and frequent blood draws. Frequent reassessment for hypoglycemia and infection is also essential.
- If APAP level is nontoxic, *N*-acetylcysteine therapy may be discontinued.

DISPOSITION

All patients with confirmed APAP poisoning will require admission, usually to an intensive care unit. Most patients (90%) will recover fully without persistent hepatic abnormalities. Hepatic failure is particularly unusual in children <6 yr.

REFERRAL

Psychiatric referral is recommended after intentional ingestions.

AUTHOR: **Rory Merritt, MD, MEHP**

Acetaminophen Poisoning

TABLE E1 Four Stages of Acetaminophen Poisoning

Stage 1 (0-24 hr)	Asymptomatic	Patients are initially asymptomatic, with normal vital signs and no physical findings. Laboratory results are normal. Nonspecific complaints of nausea, vomiting, and malaise may start to develop near the end of this stage.
Stage 2 (24-72 hr)	Onset of hepatotoxicity	Right upper quadrant abdominal pain may develop. Levels of AST, the most sensitive indicator of hepatotoxicity, and ALT begin to rise. Later, INR values may begin to rise and renal function to deteriorate.
Stage 3 (72-96 hr)	Maximal hepatotoxicity	The patient exhibits clinical and laboratory manifestations of hepatic necrosis: Varying degrees of hepatic encephalopathy, jaundice, renal failure, coagulation defects, and myocardial abnormalities. AST and ALT levels peak, the INR value rises, blood urea nitrogen and creatinine levels rise, and pH drops. Death may occur, typically 3-5 days after overdose. Death from fulminant hepatic failure may be characterized by cerebral edema, sepsis, multisystem organ failure, hemorrhage, and acute respiratory distress syndrome.
Stage 4 (4 days to 2 wk)	Recovery phase	Patients who survive stage 3 undergo complete regeneration of the liver. Laboratory abnormalities typically return to normal 5-7 days after overdose.

ALT, Alanine transaminase; *AST,* aspartate transaminase; *INR,* international normalized ratio.

BASIC INFORMATION

DEFINITION

Achalasia is a motility disorder of the esophagus classically characterized by incomplete relaxation of the lower esophageal sphincter (LES) and aperistalsis of the esophageal smooth muscle. The result is functional obstruction of the esophagus.

SYNONYMS

Achalasia and cardiospasm
Achalasia (of cardia)
Aperistalsis of esophagus
Megaesophagus
Esophageal achalasia
Esophageal cardiospasm

ICD-10CM CODE
K22.0 Achalasia of cardia

EPIDEMIOLOGY & DEMOGRAPHICS

- Annual incidence is approximately 0.5 to 1.0 in 100,000 persons.
- Prevalence is <10 per 100,000 persons.
- Although the onset of symptoms may occur at any age, incidence is typically bimodal, 20 to 40 yr, then after 60 yr, with greater incidence in the older group.
- Men and women are affected equally.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Symptoms:
- Dysphagia (most commonly with both solids and liquids)
- Difficulty belching
- Regurgitation
- Chest pain and/or heartburn
- Globus
- Frequent hiccups
- Vomiting of undigested food
- Symptoms of aspiration such as nocturnal cough; possible dyspnea and pneumonia
- Weight loss
- The Eckardt symptom score (assessing dysphagia, regurgitation, retrosternal pain, and weight loss), a fairly reliable and valid measure of achalasia severity, may be used to assess response to therapy

Physical findings:
- Focal lung examination abnormalities and wheezing are also possible.

ETIOLOGY

- Etiology is poorly understood.
- Loss of intrinsic inhibitory neurons in the myenteric plexus in the LES and smooth muscle portion of the esophagus as well as depletion of networks of interstitial cells of Cajal of the LES result in the loss of inhibitory neurotransmitters nitric oxide and vasoactive intestinal polypeptide and unopposed excitatory cholinergic activity, leading to incomplete relaxation of the LES and loss of esophageal peristalsis.
- Loss of myenteric nerve fibers is associated with lymphocytic and eosinophilic infiltrates, capillaritis, plexitis, venulitis, nerve hypertrophy, and fibrosis.
- This disorder may be caused by autoimmune degeneration of the esophageal myenteric plexus in association with several HLA class II DQ antigens. An eight amino-acid insertion in the cytoplasmic tail of HLA-DQβ1 has been identified as a strong achalasia risk factor. Antimyenteric plexus and other antineural autoantibodies have also been described. Patients with achalasia are more likely to have other autoimmune diseases.
- Abnormal immune reactions to neurotropic viruses, such as varicella zoster, measles, and particularly herpes simplex type 1, have been implicated. A host T-cell–mediated response may lead to neuronal injury; this has been suggested as the cause of types I and II achalasia (see "Imaging Studies" section).
- Achalasia is also seen in the rare autosomal recessive disorder, Allgrove syndrome (achalasia, alacrima, autonomic disturbance, and acetylcholine insensitivity), which has been linked to a gene mutation on chromosome 12q13. Neurons in this syndrome may be susceptible to oxidative injury.
- Recent studies suggest that type III achalasia (see "Imaging Studies" section) is associated with myenteric inflammation but not neuronal loss and that downregulation of nitric oxide synthase expression and increased cholinergic sensitivity are cytokine-mediated.
- A type III achalasia pattern has been described in chronic daily opiate users.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary achalasia:
  1. Idiopathic
- Secondary achalasia:
  1. Chagas disease
  2. Vagal injury or surgery, including fundoplication
  3. Achalasia-like esophageal dilation has been described after laparoscopic gastric banding
- Pseudoachalasia (diseases that may mimic achalasia):
  1. Esophageal cancer
  2. Infiltrating gastric cancer
  3. Oat cell and bronchogenic lung cancer
  4. Lymphoma
  5. Amyloidosis
  6. Paraneoplastic syndrome
- Angina
- Bulimia
- Anorexia nervosa
- Gastric bezoar
- Gastritis
- Peptic ulcer disease
- Postvagotomy dysmotility
- Esophageal disease (Table 1):
  1. Gastroesophageal reflux disease
  2. Sarcoidosis
  3. Amyloidosis
  4. Esophageal stricture
  5. Esophageal webs and rings
  6. Scleroderma
  7. Barrett esophagus
  8. Esophagitis
  9. Diffuse esophageal spasm

WORKUP

- Physical examination and laboratory analyses to rule out other causes (Fig. 1, Table 2) and assess complications
- Imaging studies, manometry, and endoscopy (may be supportive or complementary)

LABORATORY TESTS

- Assessment of nutritional status
- Complete blood count, ECG, stress test if diagnosis is in doubt
- Serologic assays for *Trypanosoma cruzi* (Chagas disease) in appropriate individuals

IMAGING STUDIES

Barium swallow with fluoroscopy (particularly a timed barium esophagogram) may demonstrate:
- Uncoordinated or absent esophageal contractions (loss of peristalsis)

TABLE 1 Esophageal Motor Disorders

	Achalasia	Scleroderma	Diffuse Esophageal Spasm
Symptoms	Dysphagia Regurgitation of nonacidic material	Gastroesophageal reflux disease Dysphagia	Substernal chest pain (angina-like) Dysphagia with pain
Radiographic appearance	Dilated, fluid-filled esophagus Distal *bird-beak* stricture	Aperistaltic esophagus Free reflux Peptic stricture	Simultaneous noncoordinated contractions
Manometric findings	High resting pressure	Low resting pressure	Normal pressure
Lower esophageal sphincter	Incomplete or abnormal relaxation with swallow		
Body	Low-amplitude, simultaneous contractions after swallowing	Low-amplitude peristaltic contractions or no peristalsis	Some peristalsis Diffuse and simultaneous nonperistaltic contractions, occasionally high amplitude

From Andreoli TE et al: *Andreoli and Carpenter's Cecil essentials of medicine*, ed 8, Philadelphia, 2010, Saunders.

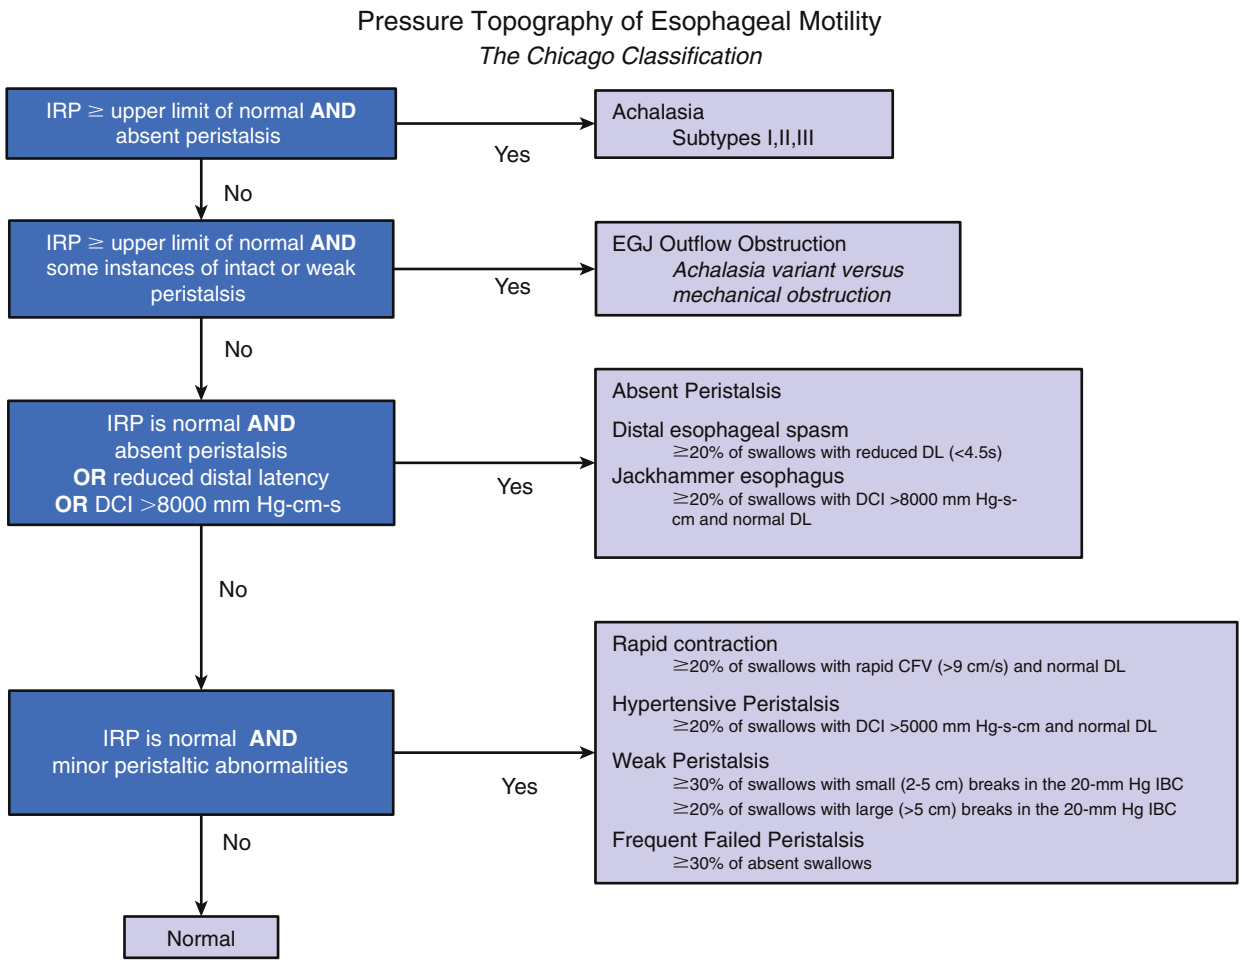

FIG. 1 Algorithm for applying the Chicago Classification of esophageal motor disorders. *CFV,* Contractile front velocity; *DCI,* distal contractile interval; *DL,* distal latency; *EGJ,* esophagogastric junction; *IBC,* isobar contour; *IRP,* integrated relaxation pressure (see Table 2 for more details). (From Feldman M et al: *Sleisenger and Fortran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.)

TABLE 2 Chicago Classification of Esophageal Motility Disorders

Diagnosis	Diagnostic Criteria
Achalasia	
Type I	100% failed peristalsis, mean IRP >10 mm Hg
Type II	No esophageal contraction and panesophageal pressurization with ≥20% of swallows; mean IRP >10 mm Hg
Type III	Premature contractions with ≥20% of swallows, mean IRP ≥17 mm Hg
EGJ outflow obstruction	Mean IRP ≥15 mm Hg; mix of normal, weak, rapid, hypertensive, failed peristalsis or panesophageal pressurization
Motility Disorders	(Patterns not observed in normal individuals)
Distal esophageal spasm	Mean IRP <17 mm Hg, ≥20% premature contractions
Hypercontractile esophagus (jackhammer esophagus)	At least one swallow DCI >8000 mm Hg·s·cm
Absent peristalsis	Mean IRP ≤10 mm Hg, 100% failed peristalsis
Peristaltic Abnormality	(Defined by exceeding statistical limits of normal)
Weak peristalsis	Mean IRP <15 mm Hg and ≥20% swallows with large breaks (≥5 cm) or ≥30% with small breaks (2-5 cm) in the 20-mm Hg isobaric contour Or DCI of 150-450 mm Hg·s·cm in ≥30% test swallows
Frequent failed peristalsis	>30%, but <100% of swallows with failed peristalsis
Rapid peristalsis	Rapid contraction with ≥20% of swallows, DL >4.5 s
Hypertensive peristalsis (nutcracker esophagus)	Mean DCI >5000 mm Hg·s·cm, but not meeting criteria for hypercontractile esophagus
Normal	Not achieving any of the above diagnostic criteria

DCI, Distal contractile interval; *DL,* distal latency; *EGJ,* esophagogastric junction; *IRP,* integrated relaxation pressure.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fortran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.

- An acutely tapered contrast column ("bird's beak"; Fig. E2)
- Dilation of the distal esophagus (smooth muscle portion)
- Esophageal air-fluid level with evidence of poor esophageal emptying
- Late-stage changes include tortuosity, angulation, dilated megaesophagus, retained food, and secretions

Manometry is considered the "gold standard" test to confirm the diagnosis.

- In classic achalasia (type I achalasia), conventional manometric abnormalities include low-amplitude disorganized contractions/aperistalsis, incomplete or absent LES relaxation (with residual pressure >10 mm Hg) after swallow, and high resting LES pressure.
- A subset of patients with "vigorous achalasia" may have high-amplitude, long-duration, simultaneous esophageal contractions. This term is now thought to be imprecise because of a newer classification of the disease.
- High-resolution manometry (HRM), or high-resolution esophageal pressure topography (HREPT), has defined subsets of patients with achalasia who may have different responses to medical or surgical therapies and prognoses. Unlike type I achalasia, type II achalasia shows panesophageal pressurization to greater than 30 mm Hg with ≥20% of test swallows, and type III achalasia shows spastic, lumen-obliterating contractions of the distal esophagus with ≥20% of swallows. This technique uses the integrated relaxation pressure (IRP) >15 mm Hg to define better the failure of esophagogastric junction relaxation. HRM also utilizes the distal contraction integral (DCI) to define hypercontractile vs. weak swallows vs. failed peristalsis. The distal latency (DL) defines premature contractions, seen with diffuse esophageal spasm and type III achalasia.
- HREPT has also defined an achalasia variant described as esophagogastric junction outflow obstruction, where the IRP is >15 mm Hg, but peristalsis is present. Some are associated with secondary causes; a small percentage may progress to achalasia; and, in many, the natural history is unclear and response to therapy is variable.
- Direct visualization by endoscopy, including careful visualization of the esophagogastric junction and cardia, should be performed to exclude other causes of dysphagia, including "functional esophagogastric junction obstruction," strictures, secondary causes of achalasia (including infiltrating cancers), and pseudoachalasia.
- Functional luminal imaging probe (FLIP) technology is a new technique that can measure compliance and distensibility across the esophagogastric junction and may demonstrate both impaired LES relaxation and response to achalasia therapy.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- The goals of therapy are to decrease LES pressure to relieve the functional obstruction, relieve symptoms, and prevent progression to a dilated esophagus, sometimes referred to as a megaesophagus. Treatment does not improve esophageal peristalsis. Achalasia is treatable but incurable.
- Pneumatic dilation (PD) to disrupt the LES muscle fibers may benefit 65% to 90% of patients. Multiple sessions may be required, and most protocols use a graded dilation approach, starting with a 30-mm balloon, and repeating if required with a 35-mm or 40-mm balloon. Some studies suggest this may be more effective in females, older patients, and particularly HRM type II patients. Esophageal rupture or perforation is a rare complication (2% to 4%) that may be managed conservatively in some stable patients with a small perforation.
- Surgical: Laparoscopic, or less commonly, open Heller esophagomyotomy (HM) is effective (90%). Approximately 35% of patients undergoing surgery will develop reflux disease. As a result, some surgeons will perform a "loose" or partial antireflux repair (fundoplication) as part of the surgical procedure. Some studies suggest this may be more effective in men and younger patients. An observational study has suggested that those who have had prior endoscopic treatment before myotomy may not do as well as those who have a primary myotomy.
- A large European study suggested that in experienced hands, patients may expect similar medium-term outcomes from myotomy and balloon dilation. A meta-analysis suggests better long-term durability of myotomy. Balloon dilation may be the more cost-effective treatment. A small percentage (20% to 30%) of patients undergoing either therapy may require re-treatment within 5 to 7 yr.
- Endoscopic submucosal myotomy (per-oral endoscopic myotomy [POEM]) has a high success rate comparable to laparoscopic HM (particularly in HRM type III patients in whom a longer myotomy, tailored to the length of the diseased segment, improves outcome), few adverse events (which can include pneumomediastinum, pneumothorax, pneumoperitoneum, pleural effusion, pneumonia, and bleeding), and exceedingly rare mortality. Because no antireflux procedure is performed, there is a modest risk (up to 53%) of developing pathologic reflux. It should only be performed at high-volume centers. A randomized multicenter study showed a higher treatment success rate for POEM at 2 years when compared with pneumatic dilation.
- FLIP and timed barium esophagogram may help determine response to therapy.
- Esophagectomy has been performed in patients with end-stage achalasia with a dilated, often sigmoid-shaped or megaesophagus, who have failed myotomy or pneumatic dilation.

ACUTE GENERAL Rx

- Medications may be useful for short-term symptom relief and in patients with refractory chest pain. They should only be considered in patients unable to receive, or who are scheduled for, more definitive procedures. LES pressure may be lowered by up to 50% through sublingual use of long-acting nitrates (e.g., isosorbide dinitrate 5 to 20 mg) or calcium channel blockers (e.g., nifedipine 10 to 30 mg). Side effects are common and duration of relief tends to be short. Sildenafil was shown to be effective in a few small, short-term studies, but it is generally not recommended.
- Botulinum toxin injection will benefit up to 85% of patients by inhibiting acetylcholine release from cholinergic nerve endings, blocking the unopposed cholinergic stimulation of the LES, but having no impact on the myogenic tone. Up to half of these patients will require repeat injections by 6 months. A few studies have suggested that repeated injections may have diminished efficacy and can lead to fibrosis, which may complicate subsequent attempts at surgical therapy.
- Many patients will require proton pump inhibitor therapy for gastroesophageal reflux after effective disruption of the LES.

PEARLS & CONSIDERATIONS

COMMENTS

- Medication has a limited role in treatment.
- Botulinum toxin is transiently effective in improving symptoms.
- Pneumatic dilation, surgical myotomy, and POEM provide more durable long-term responses and are the treatment of choice for most patients. Botulinum toxin should be considered primarily in patients too elderly or ill to be considered for these other therapies.
- Patients with achalasia may be at long-term risk of squamous cell carcinoma of the esophagus and non–reflux-associated esophagitis. Treated patients may be at long-term risk for reflux esophagitis, Barrett esophagus, and adenocarcinoma. Endoscopic surveillance is not routinely recommended in these patients.

Achilles Tendon Rupture (PTG)

BASIC INFORMATION

DEFINITION

Achilles tendon rupture is a disruption of the continuity of the Achilles tendon that either occurs as a result of forced dorsiflexion of the foot in plantar flexion or forced plantar flexion against resistance.

ICD-10CM CODES

S86.0	Unspecified injury of Achilles tendon
S86.012	Achilles tendon rupture left
S86.011	Achilles tendon rupture right
M66.871	Non traumatic Achilles tendon rupture right
M66.872	Non traumatic Achilles tendon rupture left

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: In the general population, Achilles tendon ruptures occur in 18 per 100,000 individuals per year and are the most common large tendon ruptures, accounting for 20% to 35% of all large tendon injuries in the human body. They can often be missed and initially diagnosed as an ankle sprain.
PEAK INCIDENCE: 30- to 40-year-old males
PREDOMINANT AGE: 30- to 55-years-old
RISK FACTORS: General risk factors include recreational athletes, stop-and-go sports (e.g., basketball, tennis, and soccer), preexisting Achilles tendinopathy, increase in duration or intensity of running, advanced age, male gender, and poor running mechanics. Fluoroquinolone antibiotics have been associated with Achilles tendon ruptures, with an incidence of 12 per 100,000. This is more likely to occur in first-time users of fluoroquinolones and usually occurs within the first 90 days of therapy. Additionally, corticosteroid use has been implicated in Achilles tendon rupture.

CLINICAL PRESENTATION

A classic presentation for acute Achilles tendon rupture is a middle-aged male who participates in strenuous activities involving sudden pivoting on a foot or rapid deceleration as in recreational sports. A popping sensation of the tendon may be described by some patients, followed by an acute onset of severe pain in the calf and lower leg. Patients who also attempt new strenuous activities without proper training and stretching or who typically lead a sedentary lifestyle are more likely to experience Achilles tendinopathy, including ruptures. It is important to note that pain is not always an initial presenting symptom.

PHYSICAL FINDINGS

A palpable defect in the posterior distal third of the Achilles tendon may be appreciated with palpation. Depending on the severity of the rupture, pain, ecchymosis and diffuse edema may be noted. The patient may present with an antalgic gait and the inability to perform a single heel raise on the injured limb secondary to weakened plantar flexion power. Additionally, the patient may not be able to plantarflex against resistance. Having them lie prone with their legs off the examination table may show their injured side to be more dorsiflexed compared to the contralateral side and squeezing the affected calf will not produce plantarflexion of the foot.

ETIOLOGY/MECHANISM OF INJURY

Indirect trauma is most often associated with Achilles tendon ruptures, which typically fall under three categories: mechanical, vascular, and poor tissue quality.

- Mechanical: Involves variations of a rapid loading process on an already tensed tendon such as a sudden dorsiflexion of the ankle with the knee extended while an eccentric load is applied.
- Vascular: Located 2 to 6 cm proximal to the Achilles tendon insertion is a known area of hypo vascularity.
- Poor tissue quality: Tendonitis, which is inflammation that occurs within the tendon after an acute injury, and tendinosis, which is a degeneration process from repetitive tears related to chronic injuries, are known to weaken the tendon before it is ruptured. This often occurs in the form of repetitive microtrauma from improper training techniques.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Achilles tendinopathy (tendinosis vs. tendonitis)
- Retrocalcaneal bursitis
- Ankle sprain
- Calcaneal avulsion fracture
- Partial rupture of gastrocnemius
- Plantaris rupture
- Os trigonum syndrome
- Calcaneal apophysitis

WORKUP

A thorough history and physical examination, along with a high clinical suspicion, is key to distinguishing Achilles tendon ruptures from other Achilles tendinopathies. The clinical history in most presentations is very specific, and the physical examination is usually diagnostic. The following is a list of specific clinical tests and imaging modalities.

- **Thompson test (Fig. E1):** Also known as the "calf squeeze test," it is an accurate means of detecting Achilles tendon ruptures. The patient is placed in a prone position with the knee flexed. While squeezing the gastrocnemius, the clinician evaluates for the presence or absence of ankle plantar flexion. If ankle plantar flexion is absent, the test is said to be positive and indicative of Achilles tendon rupture.
- **Matles test (knee flexion test):** The test is an additional physical examination finding utilized to assess Achilles tendon ruptures. The patient is placed in the prone position with the knees flexed at 90 degrees. If the injured foot falls in an increased dorsiflexed position instead of a resting plantar flexed position when compared to the contralateral limb, the test of the injured limb is positive for Achilles tendon rupture.

IMAGING STUDIES

- Ultrasound imaging may be used to assess Achilles tendinopathy and is considered by some the first-line imaging modality. Ultrasound provides clinicians with a practical means of evaluating Achilles tendinopathy and ruptures at the bedside.
- MRI (Fig. E2) is often utilized to further evaluate Achilles tendinopathy, especially ruptures. Discontinuity of the Achilles tendon can be seen on T2-weighted images, where the signal in the tendon is increased at the area of rupture and the tendon diameter is increased. MRI provides greater anatomic detail as well as greater accuracy in detecting partial Achilles tendon tears. MRI has proved to be superior to ultrasound in defining ruptures histologically.

TREATMENT

Initial treatment should consist of the RICE protocol (**r**est, **i**ce, **c**ompression to reduce swelling, and **e**levation). Adequate analgesics for at-home use can include acetaminophen and/or nonsteroidal antiinflammatory drugs. The patient should also be placed into a posterior slab splint with the foot in resting equinus (held at its natural plantarflexed position).

The typical course of immobilization of the injured limb ranges from a minimum of 8 to 12 weeks. Over the past few years there has been a trend in nonoperative management of Achilles tendon ruptures that include accelerated protocol to rehabilitation. These accelerated protocols have been shown to improve outcomes of nonoperative Achilles tendon management. These protocols have the patient non–weight bearing in a posterior splint or short leg cast in equinus with crutches for 2 weeks. A controlled ankle motion walker with special sequential heel wedges then follows this for the next 4 weeks of non–weight bearing with crutches. After 4 to 6 weeks the patient may return to regular shoe gear, with a heel wedge modification for an additional 2 months. During this period, it is recommended that patients start resistance exercises, proprioception and gait retraining, and sport retraining.

SURGICAL TREATMENT

If surgical intervention is warranted, it should be done within 4 weeks of the initial injury, although within 7 to 14 days of injury is ideal. Proper timing of surgical repair is imperative to postsurgical recovery. The inflammatory phase of wound healing occurs within the first 7 to 14 days following an acute Achilles tendon rupture. During this phase, vascularity to the injured tendon increases, aiding in postoperative healing.

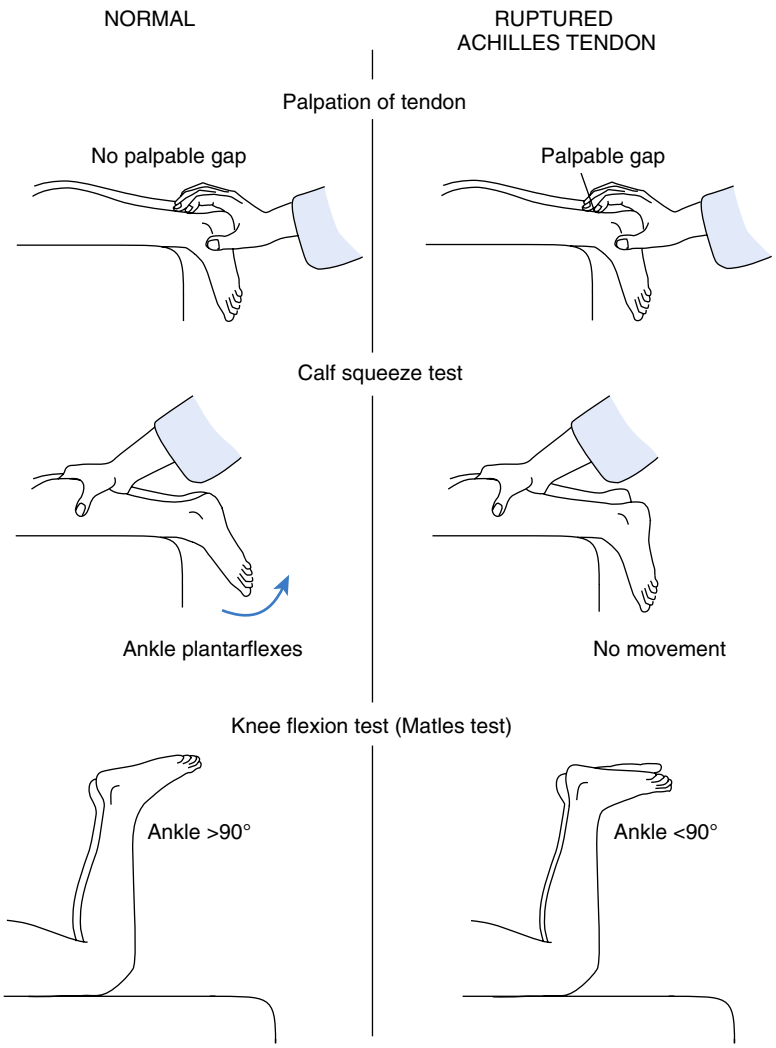

FIG. E1 Tests for rupture of the Achilles tendon. All tests are performed with the patient lying prone with his or her feet extending over the end of the examination table. [1] The patient's asymptomatic side serves as a control (for each test, a patient with an intact Achilles tendon is depicted on the *left*, compared with a patient with a ruptured Achilles tendon on the *right*). (1) Palpable gap in tendon (*top*): The clinician gently palpates the course of the tendon, searching for gaps, which if present usually lie between 2 and 6 cm from the calcaneus.[2] (2) Calf squeeze test (Thompson test, *middle*): The clinician gently squeezes the patient's calf in its middle third and just below the place of widest girth, observing the ankle for movement. If the tendon is intact, the ankle should plantarflex. Absence of movement or minimal movement is a positive response. The normal plantar flexion of the ankle results from compression of the soleus muscle, which bows the Achilles tendon posteriorly.[3] (3) Knee flexion test (Matles test, *bottom*): The clinician observes the position of the patient's ankles as the patient flexes both knees to 90 degrees (the knees may be flexed individually or simultaneously). The ankle remains slightly plantar flexed if the tendon is intact; slight dorsiflexion or a neutral position of the ankle is the positive response. Thompson described the calf squeeze test in 1962,[2] pointing out that the test could be performed with the patient prone or kneeling on a chair. Simmonds described the identical test in 1957.[4] Matles described the knee flexion test in 1975.[5] (From McGee S. *Evidence-based physical diagnosis*, ed 4, Philadelphia, 2017, Elsevier. [1] Maffulli N: The clinical diagnosis of subcutaneous tear of the Achilles tendon: a prospective study in 174 patients, *Am J Sports Med* 26[2]:266-270, 1998; [2] Thompson TC, Doherty JH: Spontaneous rupture of tendon of Achilles: a new clinical diagnostic test, *J Trauma* 2:126-129, 1962; [3] Scott BW, Chalabi AA: How the Simmonds–Thompson test works, *J Bone Joint Surg Br* 74B[2]:314-315, 1992; [4] Simmonds FA: The diagnosis of the ruptured Achilles tendon, *Practitioner* 179[1069]: 56-58, 1957; [5] Matles AL: Rupture of the tendon Achilles, *Bull Hosp Jt Dis* 36[1]:48-51, 1975.)

The primary goal of surgical treatment of Achilles tendon rupture is to reestablish appropriate tendon length and ankle plantar flexion. This is usually achieved when there is an end-to-end apposition of the damaged Achilles tendon. Several surgical techniques exist to repair the ruptured Achilles tendon, which include percutaneous repair and open operative techniques. Percutaneous repair has some advantages, including decreased operative times and decreased postoperative deep infections. However, it comes with the risk of increased sural nerve damage. After surgery, 10 to 12 weeks of immobilization followed by rehabilitation is recommended.

REFERRAL

Acute and/or complete Achilles tendon ruptures warrant surgical evaluation. Acute complete Achilles tendon ruptures are more likely to have better postoperative outcomes if addressed within 14 days of initial injury. Orthopedic surgery consultation should be obtained for symptomatic acute or chronic Achilles tendinopathy or ruptures.

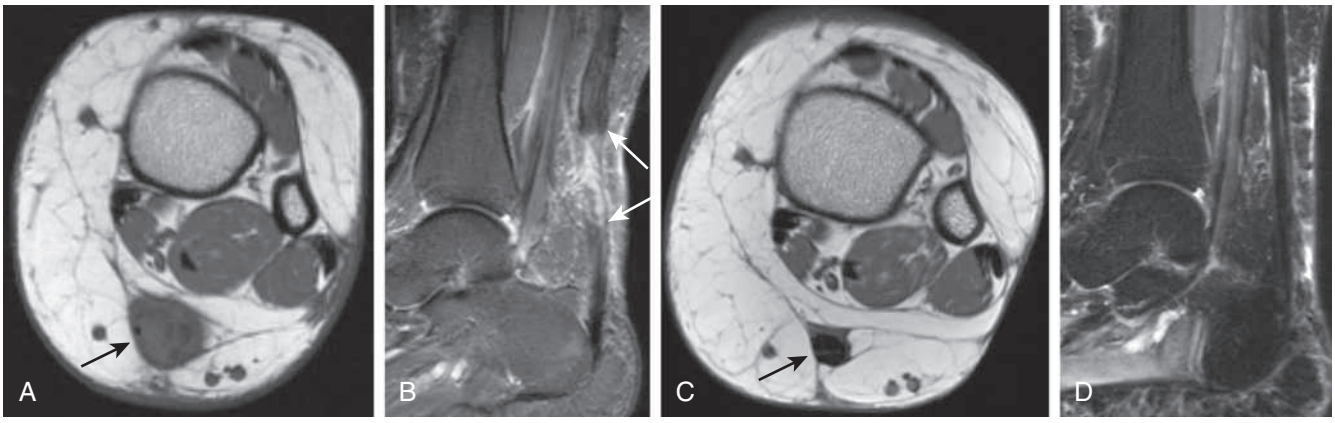

FIG. E2 Complete Achilles tendon rupture managed nonoperatively with 6 weeks of ankle casting in plantar flexion. A, Transverse T1-weighted magnetic resonance image *(MRI).* Shown is severe Achilles tendinopathy (*arrow*). **B,** Sagittal short tau inversion recovery *(STIR)* MRI reveals tendon fiber discontinuity with fluid-filled gap (*arrows*). Transverse T1-weighted **(C)** and sagittal STIR **(D)** MRIs obtained in follow-up 18 months after casting show thinning and attenuation of the tendon but reestablished tendon fiber continuity (*arrow* in **C**).

PEARLS & CONSIDERATIONS

- Patients who experience Achilles tendon ruptures may present with or without pain and may still maintain their ability to ambulate or flex their ankles. If pain is present, it usually occurs 2 to 6 cm proximal to the Achilles tendon insertion on the calcaneus.
- When evaluating Achilles tendinopathy, palpate the course of the Achilles tendon with particular attention to any edema, ecchymosis, or palpable defect or discontinuity of the tendon.
- A positive Thompson test is an accurate means for assessing Achilles tendon ruptures.
- Acute Achilles tendon ruptures should be treated within 14 days. Surgical intervention has been shown to decrease re-rupture rates when compared to nonsurgical treatment options but have higher associated complication rates.
- Although autologous platelet-rich plasma (PRP) is commonly used, trials[1] have shown that it is no better than placebo for acute Achilles tendon rupture.

[1]Keene DJ et al: Platelet rich plasma injection for acute Achilles tendon rupture: PATH-2 randomised, placebo controlled, superiority trial, *BMJ* l6132, Nov 20, 2019.

PREVENTION

- Previous tendinopathy or previous Achilles tendon ruptures are known risk factors and are associated with up to 10% of re-rupture rates.
- Physical therapy as well as physical rehabilitation protocol should be maintained following both operative and nonoperative therapies. Eccentric and concentric exercise should be continued on a regular basis following Achilles tendon ruptures and particularly before engaging in any vigorous exercise.
- The patient should reduce his or her training intensity during fluoroquinolone use and anabolic steroid use.

BASIC INFORMATION

DEFINITION

Acne vulgaris is a chronic disorder of the pilosebaceous apparatus caused by abnormal desquamation of follicular epithelium leading to obstruction of the pilosebaceous canal, resulting in inflammation and subsequent formation of papules, pustules, nodules, comedones, and scarring. Based on their appearance, the acne lesions can be divided into inflammatory (presence of papules, pustules, and nodules) or noninflammatory (open and closed comedones) For inflammatory acne, lesions can be classified as papulopustular, nodular, or both. The American Academy of Dermatology classification scheme for acne denotes the following three levels:

1. Mild acne: Characterized by the presence of comedones (Figs. E1 and E2) (noninflammatory lesions), few papules and pustules (generally <10), but no nodules.
2. Moderate acne: Presence of several to many papules and pustules (10 to 40) along with comedones (10 to 40). The presence of >40 papules and pustules along with larger, deeper nodular inflamed lesions (Figs. E3 and E4) (up to five) denotes moderately severe acne.
3. Severe acne: Presence of numerous or extensive papules and pustules as well as many nodular lesions (Fig. E5).

SYNONYM

Acne

ICD-10CM CODES

L70.0	Acne vulgaris
L70.1	Acne conglobata
L70.2	Acne varioliformis
L70.3	Acne tropica
L70.4	Infantile acne
L70.5	Acne excoriee des jeunes filles
L70.8	Other acne
L70.9	Acne, unspecified
L73.0	Acne keloid

EPIDEMIOLOGY & DEMOGRAPHICS

- Acne is the most common skin disease in the U.S.
- It is most common in teenagers, with 85% of all teenagers being affected to some degree.
- Highest incidence between ages of 15 and 18 yr in both genders.
- Involution of the disease usually occurs before age 25 yr, but 26% of women and 12% of men will continue to have clinical acne until the mid-40s.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Open comedones (blackheads), closed comedones (whiteheads)
- Greasiness (oily skin)
- Presence of scars from prior acne cysts
- Various stages of development and severity may be present concomitantly
- Common distribution of acne: face, back, and upper chest
- Inflammatory papules, pustules, and ectatic pores

ETIOLOGY

- Acne vulgaris is exclusively a follicular disease, with the principal abnormality being comedone formation.
- Overactivity of the sebaceous glands and blockage in the ducts. The obstruction leads to the formation of comedones, which can become inflamed because of overgrowth of *Propionibacterium acnes.*
- Exacerbated by environmental factors (hot, humid, tropical climate), medications (e.g., iodine in cough mixtures, hair greases), industrial exposure to halogenated hydrocarbons.
- Mechanical or frictional forces can aggravate existing acne (e.g., excessive washing by some patients to help rid them of their blackheads or oiliness).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Gram-negative folliculitis
- Staphylococcal pyoderma
- Acne rosacea
- Drug eruption
- Sebaceous hyperplasia
- Angiofibromas, basal cell carcinomas, osteoma cutis
- Occupational exposures to oils or grease
- Steroid acne
- Hidradenitis suppurativa
- Perioral dermatitis
- Pseudofolliculitis barbae
- Miliaria
- Seborrheic dermatitis

WORKUP

History and physical examination:

- Inquire about previous treatment
- Careful drug history (including all OTC products)
- Family history, history of cyclic menstrual flares
- History of use of cosmetics and cleansers
- Oral contraceptive use
- Use of medications that may worsen acne such as corticosteroids, anabolic steroids, lithium, neuroleptics, cyclosporine
- Consider the possibility of hyperandrogenic state in all women (hirsutism, irregular menses, androgenic alopecia) or children (seborrhea, acanthosis nigricans, onset of acne between ages 1 and 7 yr and no obvious external factors)

LABORATORY TESTS

- Laboratory evaluation is generally not helpful. Patients who are candidates for therapy with isotretinoin should have baseline liver enzymes, cholesterol, and triglycerides checked because this medication may result in elevation of lipids and liver enzymes.
- A negative serum pregnancy test or two negative urine pregnancy tests should also be obtained in females 1 wk before initiation of isotretinoin; it is also imperative to maintain effective contraception during and 1 mo after therapy with isotretinoin ends because of its teratogenic effects. Pregnancy status should be rechecked at monthly visits.
- If hyperandrogenism is suspected in female patients, levels of dehydroepiandrosterone sulfate (DHEAS), testosterone (total and free), and androstenedione should be measured. For women with regular menstrual cycles, serum androgen measurements generally are not necessary.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Blue light (ClearLight therapy system) can be used for treatment of moderate inflammatory acne vulgaris. Light in the violet/blue range can cause bacterial death by a photoreaction in which porphyrins react with oxygen to generate reactive oxygen species, which damage the cell membranes of *P. acnes.* Treatment usually consists of 15-min exposures twice weekly for 4 wk. Phototherapy may be effective for short-term treatment of acne, but long-term efficacy and how it compares with conventional acne therapy is unclear.
- Diet: In obese patients, dietary counseling is recommended. A high-glycemic diet may worsen acne, although the strength of its influence is controversial.

ACUTE GENERAL Rx

Treatment generally varies with the type of lesions (comedones, papules, pustules, cystic lesions) and the severity of acne. Table 1 summarizes an acne treatment algorithm. First-line treatment for mild acne vulgaris includes benzoyl peroxide, a topical retinoid, or a combination of topical medications, including topical antibiotics. Use of topical treatments for 6 to 8 weeks is required to judge their efficacy. Table E2 describes prescription topical therapies for acne.

- Comedones (noninflammatory acne) can be treated with retinoids or retinoid analogs. Topical retinoids are comedolytic and work by normalizing follicular keratinization. Commonly available agents are Adapalene (Differin, 0.1% gel or cream, applied once or twice daily), tazarotene (Tazorac 0.1% cream or gel applied daily), tretinoin (Retin-A 0.1% cream or 0.025 gel applied once daily), tretinoin microsphere (Retin-A Micro, 0.1% gel, applied at bedtime). Tretinoin is inactivated by ultraviolet light and oxidized by benzoyl peroxide; therefore it should only be applied at night and not used concomitantly with benzoyl peroxide.
- Tretinoin is pregnancy category C and tazarotene is pregnancy category X. Salicylic acid preparations (e.g., Neutrogena 2% wash) have keratolytic and antiinflammatory properties and are also useful in the treatment of comedones. Large, open comedones (blackheads) should be expressed.
- Patients should be reevaluated after 4 to 6 wk. Benzoyl peroxide gel (2.5% or 5%) may be added if the comedones become inflamed or form pustules. The most common adverse effects are dryness, erythema, and peeling. Topical antibiotics (erythromycin, clindamycin lotions or pads) can also be used in patients with significant inflammation. They reduce *P. acnes* in the pilosebaceous follicle and have

TABLE 1 Acne Treatment Algorithm

Therapy	Severity (Lesion Type)				
	Mild (Comedonal)	**Mild (Inflammatory/ Mixed)**	**Moderate (Inflammatory/Mixed)**	**Severe (Inflammatory/ Mixed)**	**Severe (Nodular/ Scarring)**
Initial therapy options[*,†]	Topical retinoid BP Salicylic acid cleanser	BP/retinoid combo BP/antibiotic combo Antibiotic/retinoid combo + BP	BP/retinoid combo BP/antibiotic combo ± topical retinoid Antibiotic/retinoid combo + BP ± oral antibiotic	BP/retinoid combo + oral antibiotic BP/antibiotic combo + topical retinoid + oral antibiotic Antibiotic/retinoid combo + BP + oral antibiotic	Isotretinoin

BP, Benzoyl peroxide.
*If combination products not available to patient, consider substitution of individual components as separate prescriptions.
†Topical dapsone may be considered in place of topical antibiotic.
‡If needed as determined by physician assessment and patient satisfaction.
Modified from Zaenglein AL, Thiboutot DM: Expert committee recommendations for acne management, *Pediatrics* 118(3):1188-99, 2006; Thiboutot D et al: New insights into the management of acne: an update from the Global Alliance to Improve Outcomes in Acne Group, *J Am Acad Dermatol* 60:S1-50, 2009; Eichenfield LF et al: Evidence-based recommendations for the diagnosis and treatment of pediatric acne, *Pediatrics* 131(3):S163-86, 2013; Thiboutot DM, Gollnick HP: Treatment considerations for inflammatory acne: clinical evidence for adapalene 0.1% in combination therapies, *J Drugs Dermatol* 5(8):785-94, 2006; Gollnick H et al: Management of acne: a report from a Global Alliance to Improve Outcomes in Acne, *J Am Acad Dermatol* 49(Suppl. 1):S1-37, 2003.

some antiinflammatory effects. The combination of 5% benzoyl peroxide and 3% erythromycin (Benzamycin) or 1% clindamycin with 5% benzoyl peroxide (BenzaClin) is highly effective in patients who have a mixture of comedonal and inflammatory acne lesions.

- Fixed-dose combinations of clindamycin phosphate 1.2% and tretinoin 0.025% are available (Veltin gel, Ziana) and are more effective than either product used alone; however, they are much more expensive than the individual generic components.
- Pustular acne can be treated with tretinoin and benzoyl peroxide gel applied on alternate evenings; drying agents (sulfacetamide-sulfa lotions [Novacet, Sulfacet]) are also effective when used in combination with benzoyl peroxide; oral antibiotics (doxycycline 100 mg qd or erythromycin 1 g qd given in 2 to 3 divided doses) are effective in patients with moderate to severe pustular acne. Patients not responding well to these antibiotics can be switched to minocycline 50 to 100 mg bid. Table E3 summarizes oral antibiotics for acne vulgaris.
- Patients with nodular cystic acne and those with moderate to severe inflammatory acne unresponsive to topical drugs can be treated with systemic agents: antibiotics (erythromycin, tetracycline, doxycycline, minocycline), isotretinoin (available on a restricted basis), or oral contraceptives. Periodic intralesional triamcinolone (Kenalog) injections by a dermatologist are also effective. The possibility of endocrinopathy should be considered in patients responding poorly to therapy.
- Isotretinoin is the most effective drug available for treatment of severe nodulocystic acne. It is indicated for acne resistant to antibiotic therapy and severe acne. It inhibits *P. acne's* colonization by reducing sebum production and has antiinflammatory and keratolytic effects. It is available only on a restricted basis. Dosage is 0.5 to 1 mg/kg/day in 2 divided doses (maximum of 2 mg/kg/day); duration of therapy is generally 20 wk for a cumulative dose ≥120 mg/kg for severe cystic acne. Before using this medication patients should undergo baseline laboratory evaluation (see "Laboratory Tests"). This drug is absolutely contraindicated during pregnancy because of its teratogenicity. It should be used with caution in patients with history of depression. Physicians, distributors, pharmacies, and patients must register in the iPLEDGE program (www.ipledgeprogram.com) before using isotretinoin.
- Azelaic acid is a bacteriostatic dicarboxylic acid used to normalize keratinization and reduce inflammation. It can be used in pregnant women.
- Oral contraceptives reduce androgen levels and therefore sebum production. They represent a useful adjunctive therapy for all types of acne in women and adolescent girls. Commonly used agents are norgestimate/ethinyl estradiol (Ortho Tri-Cyclen) and drospirenone/ethinyl estradiol (Yasmin).

REFERRAL

Referral for intralesional injection and dermabrasion should be considered in patients with severe acne unresponsive to conventional therapy. Table E4 summarizes alternative treatments for acne vulgaris.

PEARLS & CONSIDERATIONS

- Gram-negative folliculitis should be suspected if inflammatory acne worsens after several months of oral antibiotic therapy.
- Acne may worsen during the first 3 to 4 wk of retinoid therapy before improving.

COMMENTS

Indications for systemic therapy of acne are:

- Painful deep papules or nodules
- Extensive lesions
- Active acne with severe scarring or hyperpigmentation
- Patient's morale

Patients should be educated that in most cases acne can be controlled but not cured and that at least 4 to 6 wk of initial therapy should be required before significant improvement is noted.

- The negative psychological effect of acne may be severe and long-lasting.

TABLE E3 Oral Antibiotics for Acne Vulgaris

Drug	Usual Dosage*	Comments/Side-Effects
Commonly used		
Tetracycline	250-500 mg	Dental staining <9 yr
		Dairy products decrease absorption
		GI upset, photosensitivity, teratogenic, PTC, VVC, IBD
Minocycline	50-100 mg	Dental staining <9 yr
	55, 65, 80, 105, 115 mg ER (1 mg/kg once daily)	Dairy products decrease absorption
		Vertigo (lower incidence with ER preparation), GI upset, blue-gray skin pigmentation, severe drug reactions with hepatitis/pneumonitis, lupus-like reactions, SJS, teratogenic, hepatitis, PTC, VVC, IBD
Doxycycline	50-100 mg	Dental staining <9 yr
	75, 100, 150 mg ER, once daily	Dairy products decrease absorption
	20 mg ("subantimicrobial dose")	Photosensitivity, photoonycholysis, GI upset (rare), teratogenic, PTC, VVC, IBD
Erythromycin	250-500 mg	GI upset (common), VVC, drug–drug interactions, prolongation of the QT interval; no longer recommended by most experts given increased resistance
Less commonly used		
Trimethoprim-sulfamethoxazole	80/400 mg, 160/800 mg	Severe drug reactions, SJS, bone marrow suppression, hepatitis, GI upset, VVC, fixed drug eruption; routine use for acne strongly discouraged
Clindamycin	75-150 mg	Pseudomembranous colitis, GI upset, drug reactions, VVC
Cephalexin	250-500 mg	GI upset, drug reactions, VVC

ER, Extended release formulation; *GI,* gastrointestinal; *IBD,* inflammatory bowel disease; *PTC,* pseudotumor cerebri; *SJS,* Stevens–Johnson syndrome; *VVC,* vulvovaginal candidiasis.
*Usually given twice daily for acne unless otherwise noted in table.

TABLE E4 Alternative Treatments for Acne Vulgaris

Treatment	Comment
Comedone extraction	Performed with comedone extractor
Injections	Intralesional triamcinolone injected into large cysts or nodules
Light therapy	Blue light (may photoinactivate *P. acnes*)
	Red light (may have antiinflammatory effect)
	Combination blue-red light
	Intense pulsed light (IPL)
	Photodynamic therapy (PDT)
Laser therapy	KTP, pulsed dye laser (rarely used)
	Resurfacing laser (including both nonablative and ablative resurfacing lasers); useful for acne scarring
Dermabrasion/dermasanding	Useful for acne scarring
Collagen injection	Useful for acne scarring
Chemical peels	Useful for acne scarring and hyperpigmentation
Punch grafts/tissue augmentation	Useful for acne scarring
Trichloroacetic acid	Useful for atrophic acne scars
Radiation therapy	Outdated modality

KTP, Potassium titanyl phosphate.
From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.

FIG. E1 Acne vulgaris: comedonal. Open comedones present as blackheads. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

FIG. E2 Acne vulgaris: comedonal. Closed comedones present as whiteheads. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

FIG. E3 Acne vulgaris: inflammatory. Note the erythematous papules and pustules, as well as open and closed comedones. (From Paller AS, Mancini, AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

FIG. E4 Acne vulgaris: inflammatory. This adolescent female has inflammatory papules and papulopustules, as well as hirsutism. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

FIG. E5 Acne vulgaris: nodulocystic. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

Acoustic Neuroma PTG

BASIC INFORMATION

DEFINITION

Acoustic neuroma is a benign proliferation of the Schwann cells that cover the vestibular branch of the eighth cranial nerve (CN VIII). Symptoms are commonly a result of compression of the acoustic branch of CN VIII, the facial nerve (CN VII), and the trigeminal nerve (CN V). The glossopharyngeal nerve (CN IX) and vagus nerve (CN X) are less commonly involved. In extreme cases, compression of the brain stem may lead to obstruction of cerebrospinal fluid (CSF) outflow and elevated intracranial pressure (ICP).

SYNONYMS

Vestibular schwannoma
Acoustic schwannoma

ICD-10CM CODE
D33.3 Benign neoplasm of cranial nerves

EPIDEMIOLOGY & DEMOGRAPHICS

Overall incidence is approximately 1 in 100,000 person-yr with a higher incidence in patients with neurofibromatosis type 2 (NF2). In the U.S., there are about 3000 new cases of acoustic neuroma diagnosed each year. The tumor most commonly presents in the fifth and sixth decades.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most frequently unilateral hearing loss and/or tinnitus. Also balance problems, vertigo, facial pain (trigeminal neuralgia) and weakness, difficulty swallowing, fullness or pain of the involved ear. Headache may occur.
- With elevated ICP, patients may also have vomiting, fever, and visual changes.
- Hearing loss is the most common presenting complaint and is usually high frequency.

ETIOLOGY

The etiology is incompletely understood, but long-term exposure to acoustic trauma has been implicated. Bilateral acoustic neuromas may be inherited in an autosomal-dominant manner as part of NF2. This disease is associated with a defect on chromosome 22q1. Childhood exposure to low-dose radiation for benign head and neck conditions may increase risk for acoustic neuromas. There is inconclusive evidence to link chronic exposure to radiofrequency radiation from cellular telephone use and the risk for developing brain tumors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Benign positional vertigo
- Menière disease
- Trigeminal neuralgia
- Cerebellar disease
- Normal-pressure hydrocephalus
- Presbycusis
- Glomus tumors
- Vertebrobasilar insufficiency
- Ototoxicity from medications
- Other tumors:
  1. Meningioma, glioma
  2. Facial nerve schwannoma
  3. Cavernous hemangioma
  4. Metastatic tumors

WORKUP

- A detailed neurologic examination with special attention to the cranial nerves is crucial.
- Rinne and Weber tests help determine conductive or sensorineural hearing loss.
- Common office balance tests (i.e., Romberg, Dix-Hallpike) are typically normal.
- Otoscopic evaluation may help rule out other causes of hearing loss.

LABORATORY TESTS

- Audiometry is useful, often showing asymmetric, sensorineural, high-frequency hearing loss.
- CSF protein may be elevated.

IMAGING STUDIES

- MRI with gadolinium (Fig. 1) is the preferred test. It can detect tumors as small as 2 mm in diameter.
- High-resolution CT scan with and without contrast can detect tumors 1 cm in diameter or larger.
- Treatment decisions should be based on the size of the tumor, rate of growth (older patients tend to have slower-growing tumors), degree of neurologic deficit, desire to preserve hearing, life expectancy, age of the patient, and surgical risk. A combination of treatments can also be used.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Surgery is the definitive treatment. Choice of approach (middle cranial fossa, translabyrinthine, or retromastoid suboccipital) may vary depending on the size of the tumor, amount of residual hearing desired, and degree of surgical risk that can be tolerated. Partial resection is sometimes undertaken to minimize the risk of injury to nearby structures. Intraoperative facial nerve monitoring is recommended.
- Radiation therapy (stereotactic radiotherapy, stereotactic radiosurgery, or proton beam radiotherapy) is useful for tumors <3 cm in diameter or for those in whom surgery is not an option. Radiotherapy after partial resection has also been used to minimize complications.
- Age alone is not a contraindication to surgery.

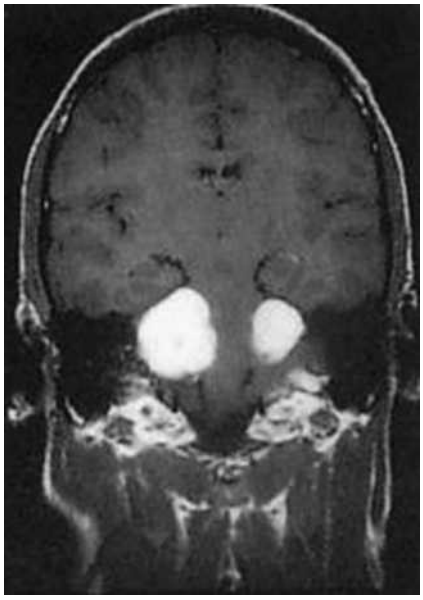

FIG. 1 Magnetic resonance imaging with enhancement shows bilateral acoustic neuromas. Coronal view. (From Kanski JJ, Bowling B: *Clinical ophthalmology, a systematic approach*, ed 7, Philadelphia, 2011, Saunders.)

GENERAL Rx

- Bevacizumab, an antivascular endothelial growth factor (VEGF) monoclonal antibody, has been shown to improve hearing and reduce the volume of growing acoustic neuromas in some neurofibromatosis type 2 patients.
- Observation with MRI every 6 to 12 mo may be appropriate for frail patients with small tumors, but risk of unrecoverable hearing loss may increase if surgery is delayed. Also, progressive hearing loss may occur despite absence of growth on subsequent imaging.

DISPOSITION

Hearing can be preserved at near-preoperative levels in more than two thirds of patients with small- to medium-sized tumors. Occurrence of secondary radiation-related tumors following radiosurgery is rare. There are no standard posttreatment follow-up recommendations. Therefore, an individualized approach to follow-up imaging and audiometry is recommended.

REFERRAL

Prompt referral to an otolaryngologist or neurosurgeon who is facile with all three surgical approaches is recommended.

PEARLS & CONSIDERATIONS

COMMENTS

- Presents most commonly as unilateral, sensorineural hearing loss.
- Treatment outcomes are excellent, with surgical cure rates greater than 95%.
- Of those who are managed with observation only, approximately half have continued enlargement, and approximately one-fifth eventually have a surgical intervention.

BASIC INFORMATION

DEFINITION

Acquired immunodeficiency syndrome (AIDS) is a disorder caused by infection with the human immunodeficiency virus (HIV) and marked by progressive deterioration of the cellular immune system, leading to secondary (opportunistic) infections and/or malignancies.

SYNONYM

AIDS

ICD-10CM CODE

B20 Human immunodeficiency virus [HIV] disease

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- The estimated number of persons diagnosed with AIDS in the U.S. is approximately 18,000/yr.
- There is a disproportionate number of new AIDS cases among black/African Americans and Latino/Hispanic Americans compared with white Americans.
- The majority of all new AIDS diagnoses are among gay, bisexual, or other men who have sex with men (MSM).

PREVALENCE (IN U.S.): The cumulative number of AIDS diagnoses in the U.S. exceeds 1.2 million.

PREDOMINANT SEX: Men constitute approximately 75% of incident AIDS diagnoses in the U.S.; more than half of AIDS diagnoses occur in MSM.

PREDOMINANT AGE: The predominant age group diagnosed with AIDS is 25 to 59 yr of age.

PEAK INCIDENCE: Ages 25 to 59 yr

GENETICS:

- Familial disposition: Although there is no proven genetic predisposition, individuals with deletions in the *CCR5* gene are less susceptible to HIV infection with macrophage tropic virus (the predominant virus in sexual transmission) and may progress to AIDS more slowly.
- Congenital infection:
  1. HIV is transmittable from an infected mother to the fetus in utero in as many as 30% of pregnancies if untreated.
  2. No specific congenital malformations associated with infection; low birth weight and spontaneous abortion are possible.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Nonspecific findings: Fever, weight loss, anorexia
- Specific syndromes:
  1. Seen in association with specific opportunistic infections and malignancies. These include:
     a. Opportunistic infections:
        (1) Disseminated strongyloidiasis
        (2) Disseminated toxoplasmosis, cryptococcosis, histoplasmosis, cytomegalovirus (CMV), herpes simplex virus (HSV), or mycobacterial disease (most common is mycobacterium avium complex)
        (3) *Candida* esophagitis or bronchopulmonary disease
        (4) Chronic cryptosporidiosis diarrhea
        (5) *Pneumocystis jiroveci* pneumonia (PJP)
        (6) Extensive pulmonary and extrapulmonary tuberculosis (TB)
        (7) Recurrent pneumonia or other bacterial infections
        (8) Progressive multifocal leukoencephalopathy (PML)
     b. AIDS-related neoplasms:
        (1) Kaposi sarcoma
        (2) Primary brain lymphoma
        (3) Invasive cervical carcinoma
        (4) High-grade B-cell non-Hodgkin lymphoma, Burkitt lymphoma, undifferentiated non-Hodgkin lymphoma, or immunoblastic lymphoma
  2. Most common:
     a. Respiratory infections (*Pneumocystis jiroveci* [formerly known as *Pneumocystis carinii*] pneumonia, TB, bacterial pneumonia, fungal infection)
     b. CNS infections (toxoplasmosis, TB)
     c. GI (cryptosporidiosis, isosporiasis, CMV); Sections II and III describe organisms associated with diarrhea in patients with AIDS
     d. Eye infections (CMV, toxoplasmosis)
     e. Kaposi sarcoma (cutaneous or visceral) or lymphoma (nodal or extranodal)
- Possibly asymptomatic
- Diagnosis of AIDS if the CD4 cell count is <200 or <14% of total lymphocyte in the presence of proven HIV infection, even in the absence of other infections
- The various manifestations of HIV infection are described in Section II

ETIOLOGY

- Caused by infection with HIV-1 or HIV-2 (less common).
- HIV is transmitted by sexual contact, needle-sharing (during IV drug use), transfusion of contaminated blood or blood products, and from infected mother to fetus or neonate.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other wasting illnesses mimicking the nonspecific features of AIDS:
  1. TB
  2. Neoplasms
  3. Disseminated fungal infection
  4. Malabsorption syndromes
  5. Depression
- Other disorders associated with dementia or demyelination producing encephalopathy, myelopathy, or neuropathy

WORKUP

Prompt evaluation of respiratory, CNS, and GI complaints

LABORATORY TESTS

- HIV antibody testing. See "Human Immunodeficiency Virus" topic for the updated surveillance case definition for HIV infection.
- CD4 cell count: Performed to determine the degree of immunodeficiency.
- Viral load assay: To plan long-term antiviral therapy and to follow progression and success of treatment (i.e., HIV RNA PCR).
- CSF examination: For meningitis or neurologic disease (if indicated).
- Serologic tests for syphilis, hepatitis A, hepatitis B, hepatitis C, and toxoplasmosis.
- Testing for other sexually transmitted infections (STIs) such as syphilis, gonorrhea, and chlamydia.
- Genotypic resistance testing: Used to assess for primary resistance in naïve patients and secondary resistance in patients failing a regimen.
- Eye exam: To evaluate for CMV retinitis in patients with CD4 counts <50 cells/mm^3.
- Cryptococcal antigen: Part of the evaluation in AIDS patients with CD4 counts <100 cells/mm^3 who have fever, diffuse pneumonia, or evidence of meningitis.
- Evaluation for infection with mycobacterium (TB or MAI) including a tuberculin skin test (TST) or interferon-gamma release assay (IGRA), sputum cultures, chest radiograph, and blood cultures for acid-fast bacteria, depending on clinical presentation.

IMAGING STUDIES

- MRI or CT of head for encephalopathy or focal CNS complications (e.g., toxoplasmosis [Fig. E1], lymphoma)
- Chest radiography or CT to aid in the diagnosis of *Pneumocystis jiroveci* pneumonia (PJP), TB, or bacterial pneumonia

TREATMENT

The most important aspect in management of AIDS due to HIV infection is the timely initiation of antiretroviral therapy.

NONPHARMACOLOGIC THERAPY

- Maintain adequate caloric intake.
- Encourage good oral hygiene and regular dental care.
- Avoid high-risk behaviors that increase the risk of other potential pathogens—use condoms, avoid sharing needles, etc.
- Update vaccines—particularly Tdap (tetanus, diphtheria, and pertussis), pneumococcal, meningococcal, and hepatitis A/B vaccines along with annual influenza vaccines.

- Avoid administration of any live attenuated vaccines that may be a risk to these immunocompromised patients (e.g., MMR, varicella). (See Section V for immunization schedules for HIV-infected children.)
- When feasible, avoid activities that might increase risk of exposure to opportunistic infections (e.g., cleaning out a cat litter box [toxoplasmosis], getting scratched by a cat [*Bartonella* infections], exposure to pet reptiles [salmonellosis], traveling to developing countries [cryptosporidiosis, tuberculosis], eating undercooked foods and drinking from unsafe water supplies, etc.). A description of enteropathogens causing infections in HIV-infected patients is provided in Table 1.

ACUTE GENERAL Rx

Acute management of opportunistic infections is summarized in Table 2 and reviewed elsewhere in this text under specific AIDS-related disorders. For management of AIDS-related malignancies, please refer to the specific malignancy elsewhere in this text.

CHRONIC Rx

For all HIV-infected patients, particularly those meeting the case definition of AIDS:

- Preventive therapy for *Pneumocystis jiroveci* pneumonia and *Mycobacterium avium* (see specific chapters elsewhere in this text). With appropriate antiretroviral therapy, many patients experience substantial restoration of cellular immune function. Preventive therapy for *Pneumocystis jiroveci* can be safely stopped if the CD4 cell count rises above 200 for at least 3 mo
- Based on the Department of Health and Human Services (DHHS) Guidelines, active antiretroviral therapy (ART) should be started regardless of CD4 cell count. Individuals with CD4 cell counts <350 and especially CD4 cell counts <200 should be strongly encouraged to start ART in a timely fashion
- ART usually includes three-drug combinations of:
  1. Nucleoside reverse transcriptase inhibitors (NRTI): Tenofovir disoproxil fumarate (TDF), tenofovir alafenamide fumarate (TAF), lamivudine (3TC), emtricitabine (FTC), and abacavir (ABC). Older drugs such as zidovudine (AZT), didanosine (ddI), and stavudine (d4T) are generally not recommended.
  2. Protease inhibitors (PI): Atazanavir or darunavir
  3. Nonnucleoside reverse transcriptase inhibitors (NNRTI): Nevirapine, efavirenz (EFV), etravirine, and rilpivirine
  4. Integrase inhibitors: Raltegravir, elvitegravir, bictegravir, and dolutegravir
  5. Others: Maraviroc, enfuvirtide, and ibalizumab

	Cytomegalovirus[a]
	Entamoeba histolytica
	Herpes simplex virus[a]
	Salmonella species[a]
	Enteroaggregative *E. coli*
	Shigella species

[a]Diseases of the gastrointestinal tract that fulfill the Centers for Disease Control and Prevention surveillance case definition of AIDS.

From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

The medications ritonavir or cobicistat are usually used in combination with other protease inhibitors or integrase inhibitors to obtain more sustained drug levels. Usual initial dosing regimens include two NRTIs and an NNRTI or PI or integrase inhibitor. Currently, integrase inhibitors are recommended as first-line drugs because of tolerability. Examples of initial regimens recommended by the guidelines:

1. Bictegravir/tenofovir/emtricitabine
2. Dolutegravir/abacavir/lamivudine (in patients who are HLA-B*5701 NEGATIVE)
3. Dolutegravir plus tenofovir/emtricitabine*
4. Raltegravir plus tenofovir/emtricitabine*
5. Elvitegravir/cobicistat/tenofovir/emtricitabine
6. Darunavir/ritonavir or darunavir/cobicistat plus tenofovir/emtricitabine

*Tenofovir-based formulations can include tenofovir disoproxil fumarate (TDF) or tenofovir alafenamide (TAF).

Previous first-line drugs, including efavirenz/tenofovir/emtricitabine and rilpivirine/tenofovir/emtricitabine, are now considered alternative regimens.

All these drugs have unique and class-specific side effects and require careful and expert follow-up to achieve optimal antiviral effects, ensure compliance, and maintain efficacy. Antiviral response should be monitored by baseline HIV viral load and CD4 count and repeat measurement at 2 wk and 4 wk into treatment and then periodically (3 to 6 mo) to ensure viral suppression.

- The approach to a patient with CNS signs and symptoms is described in Fig. E2, and Fig. E3 describes the management of CNS mass lesions.
- Genotypic resistance testing is strongly encouraged for all patients initiating treatment and for any patient failing antiretroviral therapy. Poor adherence to therapy, however, often underlies virologic failure.

DISPOSITION

The outlook for HIV has changed radically since the advent of ART from an essentially fatal disease to a chronic medical illness compatible with long-term survival and remarkably good quality of life. Patients should be aggressively treated for severe illnesses as outcomes following ICU admissions remain good. This is accomplished through expert and continuous follow-up, use of ART, and careful detail to compliance to medications and lifestyle modification.

REFERRAL

All patients with HIV should be referred to a physician knowledgeable and experienced in the management of the disease and its complications.

TABLE 2 Treatment of AIDS-Associated Opportunistic Infections

Opportunistic Infection	Preferred Therapy	Alternative Therapy	Other Comments
PJP	• Patients who develop PJP despite TMP-SMX prophylaxis can usually be treated with standard doses of TMP-SMX. • Duration of PJP treatment: 21 days. • *For Moderate to Severe PJP:* • TMP-SMX: (TMP 15-20 mg and SMX 75-100 mg/kg/day) IV given q6h or q8h, may switch to PO after clinical improvement. • *For Mild to Moderate PJP:* • TMP-SMX: (TMP 15-20 mg and SMX 75-100 mg/kg/day), given PO in 3 divided doses, *or* • TMP-SMX: (160 mg/800 mg or DS) 2 tablets PO tid. • *Secondary Prophylaxis, after completion of PJP treatment:* • TMP-SMX DS: 1 tablet PO daily *or* • TMP-SMX (80 mg/400 mg or SS): 1 tablet PO daily.	*For Moderate to Severe PJP:* • Pentamidine 4 mg/kg IV daily infused over ≥60 minutes; can reduce dose to 3 mg/kg IV daily because of toxicities, *or* • Primaquine 30 mg (base) PO daily + (clindamycin 600 mg q6h IV or 900 mg IV q8h) or (clindamycin 300 mg PO q6h or 450 mg PO q8h). • *For Mild to Moderate PJP:* • Dapsone 100 mg PO daily + TMP 5 mg/kg PO tid, *or* • Primaquine 30 mg (base) PO daily + (clindamycin 300 mg PO q6h or 450 mg PO q8h), *or* • Atovaquone 750 mg PO bid with food. • *Secondary Prophylaxis, after completion of PJP treatment:* • TMP-SMX DS: 1 tablet PO tiw, *or* • Dapsone 100 mg PO daily, *or* • Dapsone 50 mg PO daily + (pyrimethamine 50 mg + leucovorin 25 mg) PO weekly, *or* • (Dapsone 200 mg + pyrimethamine 75 mg + leucovorin 25 mg) PO weekly, *or* • Aerosolized pentamidine 300 mg monthly via Respirgard II nebulizer, *or* • Atovaquone 1500 mg PO daily, *or* • (Atovaquone 1500 mg + pyrimethamine 25 mg + leucovorin 10 mg) PO daily.	*Indications for Adjunctive Corticosteroids:* • Pa_{O_2} <70 mm Hg at room air, *or* • Alveolar-arterial O_2 gradient >35 mm Hg. • *Prednisone Doses (beginning as early as possible and within 72 hours of PJP therapy):* • Days 1-5: 40 mg PO bid. • Days 6-10: 40 mg PO daily. • Days 11-21: 20 mg PO daily. • IV methylprednisolone can be administered as 75% of prednisone dose. • Benefit of corticosteroid if started after 72 hours of treatment is unknown, but some clinicians will use it for moderate-to-severe PJP. • Whenever possible, patients should be tested for G6PD before use of dapsone or primaquine. Alternative therapy should be used in patients found to have G6PD deficiency. • Patients who are receiving pyrimethamine/sulfadiazine for treatment or suppression of toxoplasmosis do not require additional PJP prophylaxis. • If TMP-SMX is discontinued because of a mild adverse reaction, reinstitution should be considered after the reaction resolves. The dose can be increased gradually (desensitization) or be reduced, or the frequency can be modified. • TMP-SMX should be permanently discontinued in patients with possible or definite Stevens–Johnson syndrome or toxic epidermal necrosis.
Toxoplasma gondii encephalitis	*Treatment of Acute Infection:* • Pyrimethamine 200 mg PO 1 time, followed by weight-based therapy: • If <60 kg, pyrimethamine 50 mg PO once daily + sulfadiazine 1000 mg PO q6h + leucovorin 10-25 mg PO once daily. • If ≥60 kg, pyrimethamine 75 mg PO once daily + sulfadiazine 1500 mg PO q6h + leucovorin 10-25 mg PO once daily. • Leucovorin dose can be increased to 50 mg daily or bid. • *Duration for Acute Therapy:* • At least 6 wk; longer duration if clinical or radiologic disease is extensive or response is incomplete at 6 wk. • *Chronic Maintenance Therapy:* • Pyrimethamine 25-50 mg PO daily + sulfadiazine 2000-4000 mg PO daily (in 2-4 divided doses) + leucovorin 10-25 mg PO daily (AI). • After collecting specimen for culture and molecular diagnostic tests, empiric TB treatment should be started in individuals with clinical and radiographic presentation suggestive of TB. • *Initial Phase (2 mo, given daily):* • INH + [RIF or RFB] + PZA + EMB.	*Treatment of Acute Infection:* • Pyrimethamine (leucovorin)* + clindamycin 600 mg IV or PO q6h *or* • TMP-SMX (TMP 5 mg/kg and SMX 25 mg/kg) IV or PO bid, *or* • Atovaquone 1500 mg PO bid with food + pyrimethamine (leucovorin), *or* • Atovaquone 1500 mg PO bid with food + sulfadiazine 1000-1500 mg PO q6h (weight-based dosing, as in preferred therapy) *or* • Atovaquone 1500 mg PO bid with food, *or* • Pyrimethamine (leucovorin)* + azithromycin 900-1200 mg PO daily. • *Chronic Maintenance Therapy:* • Clindamycin 600 mg PO q8h + (pyrimethamine 25-50 mg + leucovorin 10-25 mg) PO daily *or* • TMP-SMX DS 1 tablet bid, *or* • Atovaquone 750-1500 mg PO bid + (pyrimethamine 25 mg + leucovorin 10 mg) PO daily, *or* • Atovaquone 750-1500 mg PO bid + sulfadiazine 2000-4000 mg PO daily (in 2-4 divided doses), *or* • Atovaquone 750-1500 mg PO bid with food.	• Adjunctive corticosteroids (e.g., dexamethasone) should only be administered when clinically indicated to treat mass effect associated with focal lesions or associated edema; discontinue as soon as clinically feasible. • Anticonvulsants should be administered to patients with a history of seizures and continued through acute treatment but should not be used as seizure prophylaxis. • If clindamycin is used in place of sulfadiazine, additional therapy must be added to prevent PCP.
Mycobacterium tuberculosis disease (TB)	• *Continuation Phase:* • INH + (RIF or RFB) daily. • *Total Duration of Therapy (for drug-susceptible TB):* • Pulmonary TB: 6 mo.	*Treatment for Drug-Resistant TB* • *Resistant to INH:* • (RIF or RFB) + EMB + PZA + (moxifloxacin or levofloxacin) for 2 mo; followed by (RIF or RFB) + EMB + (moxifloxacin or levofloxacin) for 7 mo.	• Adjunctive corticosteroid improves survival for TB meningitis and pericarditis. See text for drug, dose, and duration recommendations. • RIF *is not recommended* for patients receiving HIV PI because of its induction of PI metabolism. • RFB is a less potent CYP3A4 inducer than RIF and is preferred in patients receiving PIs.

Continued

TABLE 2 Treatment of AIDS-Associated Opportunistic Infections—cont'd

Opportunistic Infection	Preferred Therapy	Alternative Therapy	Other Comments
	• Pulmonary TB and culture-positive after 2 mo of TB treatment: 9 mo. • Extrapulmonary TB with CNS infection: 9-12 mo. • Extrapulmonary TB with bone or joint involvement: 6 to 9 mo. • Extrapulmonary TB in other sites: 6 mo. • Total duration of therapy should be based on number of doses received, not on calendar time.	• *Resistant to Rifamycins ± Other Drugs:* • Regimen and duration of treatment should be individualized based on resistance pattern, clinical and microbiologic responses, and in close consultation with experienced specialists.	• Once-weekly rifapentine can result in development of rifamycin resistance in HIV-infected patients and *is not recommended.* • Therapeutic drug monitoring should be considered in patients receiving rifamycin and interacting ART. • Paradoxical IRIS that is not severe can be treated with NSAIDs without a change in TB or HIV therapy. • For severe IRIS reaction, consider prednisone and taper over 4 wk based on clinical symptoms. For example: • *If receiving RIF:* Prednisone 1.5 mg/kg/day for 2 wk, then 0.75 mg/kg/day for 2 weeks. • *If receiving RFB:* Prednisone 1.0 mg/kg/day for 2 wk, then 0.5 mg/kg/day for 2 wk. • A more gradual tapering schedule over a few mo may be necessary for some patients.
Disseminated MAC disease	*At Least 2 Drugs as Initial Therapy with:* • Clarithromycin 500 mg PO bid + ethambutol 15 mg/kg PO daily, *or* • Azithromycin 500-600 mg + ethambutol 15 mg/kg PO daily if drug interaction or intolerance precludes the use of clarithromycin. • *Duration:* • At least 12 mo of therapy, can discontinue if no signs and symptoms of MAC disease and sustained (>6 mo) CD4 count >100 cells/μl in response to ART.	• Addition of a third or fourth drug should be considered for patients with advanced immunosuppression (CD4 counts <50 cells/μl), high mycobacterial loads (>2 log CFU/ml of blood), or in the absence of effective ART. *Third or Fourth Drug Options May Include:* • RFB 300 mg PO daily (dosage adjustment may be necessary based on drug interactions), *or* • Amikacin 10-15 mg/kg IV daily, *or* • Streptomycin 1 g IV or IM daily, *or* • Moxifloxacin 400 mg PO daily or levofloxacin 500 mg PO daily.	• Testing of susceptibility to clarithromycin and azithromycin is recommended. • NSAIDs can be used for patients who experience moderate to severe symptoms attributed to IRIS. • If IRIS symptoms persist, short-term (4-8 wk) systemic corticosteroids (equivalent to 20-40 mg prednisone) can be used.
Bacterial respiratory diseases *(with focus on pneumonia)*	Empiric antibiotic therapy should be initiated promptly for patients presenting with clinical and radiographic evidence consistent with bacterial pneumonia. The recommendations listed are suggested empiric therapy. The regimen should be modified as needed once microbiologic results are available. *Empiric Outpatient Therapy:* • A PO β-lactam + a PO macrolide (azithromycin or clarithromycin). • *Preferred β-lactams*: High-dose amoxicillin or amoxicillin/clavulanate. • *Alternative β-lactams*: Cefpodoxime or cefuroxime, *or* • *For penicillin-allergic patients:* Levofloxacin 750 mg PO once daily, or moxifloxacin 400 mg PO once daily. • *Duration:* 7-10 days (a minimum of 5 days). Patients should be afebrile for 48-72 hours and clinically stable before stopping antibiotics. • *Empiric Therapy for Non-ICU Hospitalized Patients:* • An IV β-lactam + a macrolide (azithromycin or clarithromycin). • *Preferred β-lactams:* Ceftriaxone, cefotaxime, *or* ampicillin-sulbactam. • *For penicillin-allergic patients:* • Levofloxacin, 750 mg IV once daily, *or* moxifloxacin, 400 mg IV once daily. • *Empiric Therapy for ICU Patients:* • An IV β-lactam + IV azithromycin, *or*	*Empiric Outpatient Therapy:* • A PO β-lactam + PO doxycycline. • *Preferred β-lactams*: High-dose amoxicillin or amoxicillin/clavulanate. • *Alternative β-lactams*: Cefpodoxime or cefuroxime. • *Empiric Therapy for Non-ICU Hospitalized Patients:* • An IV β-lactam + doxycycline. • *Empiric Therapy for ICU Patients:* • *For penicillin-allergic patients:* Aztreonam IV + (levofloxacin 750 mg IV once daily or moxifloxacin 400 mg IV once daily). *Empiric Therapy for Patients at Risk of Pseudomonas Pneumonia:* • An IV antipneumococcal, antipseudomonal β-lactam + an aminoglycoside + azithromycin, *or*	• Fluoroquinolones should be used with caution in patients in whom TB is suspected but is not being treated. • Empiric therapy with a macrolide alone is not routinely recommended because of increasing pneumococcal resistance. • Patients receiving a macrolide for MAC prophylaxis should not receive macrolide monotherapy for empiric treatment of bacterial pneumonia. • For patients begun on IV antibiotic therapy, switching to PO should be considered when they are clinically improved and able to tolerate oral medications. • Chemoprophylaxis can be considered for patients with frequent recurrences of serious bacterial pneumonia.

TABLE 2 Treatment of AIDS-Associated Opportunistic Infections—cont'd

Opportunistic Infection	Preferred Therapy	Alternative Therapy	Other Comments
	• An IV β-lactam + (levofloxacin 750 mg IV once daily or moxifloxacin 400 mg IV once daily). • *Preferred β-lactams*: Ceftriaxone, cefotaxime, or ampicillin-sulbactam. • *Empiric Therapy for Patients at Risk of* Pseudomonas *Pneumonia:* • An IV antipneumococcal, antipseudomonal β-lactam + ciprofloxacin 400 mg IV q8-12h or levofloxacin 750 mg IV once daily. • *Preferred β-lactams*: Piperacillin-tazobactam, cefepime, imipenem, or meropenem. • *Empiric Therapy for Patients at Risk for Methicillin-Resistant* Staphylococcus aureus *Pneumonia:* • Add vancomycin IV or linezolid (IV or PO) to the baseline regimen. • Addition of clindamycin to vancomycin (but not to linezolid) can be considered for severe necrotizing pneumonia to minimize bacterial toxin production.	• Above β-lactam + an aminoglycoside + (levofloxacin 750 mg IV once daily or moxifloxacin 400 mg IV once daily), *or* • *For penicillin-allergic patients*: Replace the β-lactam with aztreonam.	• Clinicians should be cautious about using antibiotics to prevent recurrences because of the potential for developing drug resistance and drug toxicities.
Bacterial enteric infections *Empiric therapy pending definitive diagnosis*	• Diagnostic fecal specimens should be obtained before initiation of empiric antibiotic therapy. • Empiric antibiotic therapy is indicated for patients with advanced HIV (CD4 count <200 cells/μl or concomitant AIDS-defining illnesses), with clinically severe diarrhea (>6 stools/day), and/or accompanying fever or chills. • *Empiric Therapy:* • Ciprofloxacin 500-750 mg PO (or 400 mg IV) q12h. • Therapy should be adjusted based on the results of diagnostic workup. • For patients with chronic diarrhea (>14 days) without severe clinical signs, empiric antibiotics therapy is not necessary; can withhold treatment until a diagnosis is made.	*Empiric Therapy:* • Ceftriaxone 1 g IV q24h, *or* • Cefotaxime 1 g IV q8h.	• Hospitalization with IV antibiotics should be considered in patients with marked nausea, vomiting, diarrhea, electrolyte abnormalities, acidosis, and blood pressure instability. • Oral or IV rehydration if indicated. • Antimotility agents should be avoided if there is concern about inflammatory diarrhea, including *Clostridium difficile*–associated diarrhea. • If no clinical response after 5-7 days, consider follow-up stool culture with antibiotic susceptibility testing or alternative diagnostic tests (e.g., toxin assays, molecular testing), alternative diagnosis, or antibiotic resistance.
Salmonellosis	All HIV-infected patients with salmonellosis should be treated because of high risk of bacteremia. • Ciprofloxacin 500-750 mg PO (or 400 mg IV) q12h, if susceptible. • *Duration of Therapy:* • *For gastroenteritis without bacteremia:* • If CD4 count ≥200 cells/μl: 7-14 days. • If CD4 count <200 cells/μl: 2-6 wk. *For gastroenteritis with bacteremia:* • If CD4 count ≥200/μl: 14 days; longer duration if bacteremia persists or if the infection is complicated (e.g., if metastatic foci of infection are present). • If CD4 count <200 cells/μl: 2-6 wk. *Secondary Prophylaxis Should Be Considered for:* • Patients with recurrent *Salmonella* gastroenteritis ± bacteremia, *or* • Patients with CD4 <200 cells/μl with severe diarrhea.	• Levofloxacin 750 mg (PO or IV) q24h, *or* • Moxifloxacin 400 mg (PO or IV) q24h, *or* • TMP, 160 mg-SMX 800 mg (PO or IV) q12h, *or* • Ceftriaxone 1 g IV q24h, *or* • Cefotaxime 1 g IV q8h.	• Oral or IV rehydration if indicated. • Antimotility agents should be avoided. • The role of long-term secondary prophylaxis in patients with recurrent *Salmonella* bacteremia is not well established. Must weigh benefit against risks of long-term antibiotic exposure. • Effective ART may reduce the frequency, severity, and recurrence of *Salmonella* infections.

Continued

TABLE 2 Treatment of AIDS-Associated Opportunistic Infections—cont'd

Opportunistic Infection	Preferred Therapy	Alternative Therapy	Other Comments
Mucocutaneous candidiasis	*For Oropharyngeal Candidiasis; Initial Episodes (for 7-14 days):* • *Oral therapy* • Fluconazole 100 mg PO daily, *or* • *Topical therapy* • Clotrimazole troches, 10 mg PO 5 times daily, *or* • Miconazole mucoadhesive buccal 50-mg tablet—apply to mucosal surface over the canine fossa once daily (do not swallow, chew, or crush). *For Esophageal Candidiasis (for 14-21 days):* • Fluconazole 100 mg (up to 400 mg) PO or IV daily, *or* • Itraconazole oral solution 200 mg PO daily. *For Uncomplicated Vulvovaginal Candidiasis:* • Oral fluconazole 150 mg for 1 dose, *or* • Topical azoles (clotrimazole, butoconazole, miconazole, tioconazole, or terconazole) for 3-7 days. *For Severe or Recurrent Vulvovaginal Candidiasis:* • Fluconazole 100-200 mg PO daily for ≥7 days, *or* • Topical antifungal ≥7 days.	*For Oropharyngeal Candidiasis; Initial Episodes (for 7-14 days):* • *Oral therapy* • Itraconazole oral solution 200 mg PO daily, *or* • Posaconazole oral solution 400 mg PO bid for 1 day, then 400 mg daily. • *Topical therapy* • Nystatin suspension 4-6 ml qid or 1-2 flavored pastilles 4-5 times daily. *For Esophageal Candidiasis (for 14-21 days):* • Voriconazole 200 mg PO or IV bid, *or* • Posaconazole 400 mg PO bid, *or* • Anidulafungin 100 mg IV 1 time, then 50 mg IV daily, *or* • Caspofungin 50 mg IV daily, *or* • Micafungin 150 mg IV daily, *or* • Amphotericin B deoxycholate 0.6 mg/kg IV daily, *or* • Lipid formulation of amphotericin B 3-4 mg/kg IV daily. *For Uncomplicated Vulvovaginal Candidiasis:* • Itraconazole oral solution 200 mg PO daily for 3-7 days.	• Chronic or prolonged use of azoles may promote development of resistance. • Higher relapse rate for esophageal candidiasis is seen with echinocandins than with fluconazole use. • Suppressive therapy is usually not recommended unless patients have frequent or severe recurrences. If Decision Is to Use Suppressive Therapy: *Oropharyngeal Candidiasis:* • Fluconazole 100 mg PO daily or tiw. • Itraconazole oral solution 200 mg PO daily. • Esophageal Candidiasis: • Fluconazole 100-200 mg PO daily. • Posaconazole 400 mg PO bid. *Vulvovaginal Candidiasis:* • Fluconazole 150 mg PO once weekly.
Cryptococcosis	*Cryptococcal Meningitis* • *Induction Therapy (for at least 2 wk, followed by consolidation therapy):* • Liposomal amphotericin B 3-4 mg/kg IV daily + flucytosine 25 mg/kg PO qid. (NOTE: Flucytosine dose should be adjusted in patients with renal dysfunction.) • *Consolidation Therapy (for at least 8 wk followed by maintenance therapy):* • Fluconazole 400 mg PO (or IV) daily. • *Maintenance therapy:* • Fluconazole 200 mg PO daily for at least 12 mo. *For Non-CNS, Extrapulmonary Cryptococcosis and Diffuse Pulmonary Disease:* • Treatment same as for cryptococcal meningitis. *Non-CNS Cryptococcosis with Mild to Moderate Symptoms and Focal Pulmonary Infiltrates:* • Fluconazole, 400 mg PO daily for 12 mo.	*Cryptococcal Meningitis* • *Induction Therapy (for at least 2 wk, followed by consolidation therapy):* • Amphotericin B deoxycholate 0.7 mg/kg IV daily + flucytosine 25 mg/kg PO qid, *or* • Amphotericin B lipid complex 5 mg/kg IV daily + flucytosine 25 mg/kg PO qid, *or* • Liposomal amphotericin B 3-4 mg/kg IV daily + fluconazole 800 mg PO or IV daily, *or* • Amphotericin B deoxycholate 0.7 mg/kg IV daily + fluconazole 800 mg PO or IV daily, *or* • Fluconazole 400-800 mg PO or IV daily + flucytosine 25 mg/kg PO qid, *or* • Fluconazole 1200 mg PO or IV daily. • *Consolidation Therapy (for at least 8 wk followed by maintenance therapy):* • Itraconazole 200 mg PO bid for 8 wk—less effective than fluconazole. • *Maintenance therapy:* • No alternative therapy recommendation.	• Addition of flucytosine to amphotericin B has been associated with more rapid sterilization of CSF and decreased risk for subsequent relapse. • Patients receiving flucytosine should have either blood levels monitored (peak level 2 hours after dose should be 30-80 μg/ml) or close monitoring of blood counts for development of cytopenia. Dosage should be adjusted in patients with renal insufficiency. • Opening pressure should always be measured when an LP is performed. Repeated LPs or CSF shunting are essential to effectively manage increased intracranial pressure. • Corticosteroids and mannitol are ineffective in reducing intracranial pressure and are *not* recommended. • Some specialists recommend a brief course of corticosteroid for management of severe IRIS symptoms.

TABLE 2 Treatment of AIDS-Associated Opportunistic Infections—cont'd

Opportunistic Infection	Preferred Therapy	Alternative Therapy	Other Comments
Histoplasmosis	*Moderately Severe to Severe Disseminated Disease Induction Therapy (for at least 2 wk or until clinically improved):* • Liposomal amphotericin B 3 mg/kg IV daily. • *Maintenance Therapy:* • Itraconazole 200 mg PO tid for 3 days, then 200 mg PO bid. *Less Severe Disseminated Disease* • Induction and Maintenance Therapy: • Itraconazole 200 mg PO tid for 3 days, then 200 mg PO bid. • *Duration of Therapy:* • At least 12 mo. *Meningitis* • *Induction Therapy (4-6 wk):* • Liposomal amphotericin B 5 mg/kg/day. • *Maintenance Therapy:* • Itraconazole 200 mg PO bid to tid for ≥1 yr and until resolution of abnormal CSF findings. • *Long-Term Suppression Therapy:* • *For patients with severe disseminated or CNS infection after completion of at least 12 mo of therapy; and those who relapse despite appropriate therapy* • Itraconazole 200 mg PO daily.	*Moderately Severe to Severe Disseminated Disease Induction Therapy (for at least 2 wk or until clinically improved):* • Amphotericin B lipid complex 3 mg/kg IV daily, *or* • Amphotericin B cholesteryl sulfate complete 3 mg/kg IV daily. • *Alternatives to Itraconazole for Maintenance Therapy or Treatment of Less Severe Disease:* • Voriconazole 400 mg PO bid for 1 day, then 200 mg bid, *or* • Posaconazole 400 mg PO bid. • Fluconazole 800 mg PO daily. *Meningitis* • No alternative therapy recommendation. • *Long-Term Suppression Therapy:* • Fluconazole 400 mg PO daily.	• Itraconazole, posaconazole, and voriconazole may have significant interactions with certain ARV agents. These interactions are complex and can be bidirectional. • Therapeutic drug monitoring and dosage adjustment may be necessary to ensure triazole antifungal and ARV efficacy and to reduce concentration-related toxicities. • Random serum concentration of itraconazole + hydroxyitraconazole should be >1 μg/ml. • Clinical experience with voriconazole or posaconazole in the treatment of histoplasmosis is limited. • Acute pulmonary histoplasmosis in HIV-infected patients with CD4 counts >300 cells/μl should be managed as nonimmunocompromised host.
Coccidioidomycosis	*Clinically Mild Infections (e.g., focal pneumonia):* • Fluconazole 400 mg PO daily *or* • Itraconazole 200 mg PO bid. *Severe, Nonmeningeal Infection (diffuse pulmonary infection or severely ill patients with extrathoracic, disseminated disease):* • Amphotericin B deoxycholate 0.7-1.0 mg/kg IV daily. • Lipid formulation amphotericin B 4-6 mg/kg IV daily. • Duration of therapy: Continue until clinical improvement, then switch to an azole. *Meningeal Infections:* • Fluconazole 400-800 mg IV or PO daily. • *Chronic Suppressive Therapy:* • Fluconazole 400 mg PO daily, *or* • Itraconazole 200 mg PO bid.	*Mild Infections (focal pneumonia) for patients who failed to respond to fluconazole or itraconazole:* • Posaconazole 200 mg PO bid, *or* • Voriconazole 200 mg PO bid. *Severe, Nonmeningeal Infection (diffuse pulmonary infection or severely ill patients with extrathoracic, disseminated disease):* • Some specialists will add a triazole (fluconazole or itraconazole, with itraconazole preferred for bone disease) 400 mg per day to amphotericin B therapy and continue triazole once amphotericin B is stopped. *Meningeal Infections:* • Itraconazole 200 mg PO tid for 3 days, then 200 mg PO bid, *or* • Posaconazole 200 mg PO bid, *or* • Voriconazole 200-400 mg PO bid, *or* • Intrathecal amphotericin B deoxycholate, when triazole antifungals are ineffective. • *Chronic suppressive therapy:* • Posaconazole 200 mg PO bid, *or* • Voriconazole 200 mg PO bid.	• Some patients with meningitis may develop hydrocephalus and require CSF shunting. • Therapy should be continued indefinitely in patients with diffuse pulmonary or disseminated diseases because relapse can occur in 25%-33% of HIV-negative patients. It can also occur in HIV-infected patients with CD4 counts >250 cells/μL. • Therapy should be lifelong in patients with meningeal infections because relapse occurs in 80% of HIV-infected patients after discontinuation of triazole therapy. • Itraconazole, posaconazole, and voriconazole may have significant interactions with certain ARV agents. These interactions are complex and can be bidirectional. Therapeutic drug monitoring and dosage adjustment may be necessary to ensure triazole antifungal and antiretroviral efficacy and to reduce concentration-related toxicities. • Intrathecal amphotericin B should be given only in consultation with a specialist and should be administered by an individual with experience with the technique.
Aspergillosis, invasive	*Preferred Therapy:* • Voriconazole 6 mg/kg IV q12h for 1 day, then 4 mg/kg IV q12h, followed by voriconazole 200 mg PO q12h after clinical improvement. • *Duration of Therapy:* • Until CD4 cell count >200 cells/μl and the infection appears to be resolved.	*Alternative Therapy:* • Lipid formulation of amphotericin B 5 mg/kg IV daily, *or* • Amphotericin B deoxycholate 1 mg/kg IV daily, *or* • Caspofungin 70 mg IV 1 time, then 50 mg IV daily, *or* • Micafungin 100-150 mg IV daily, *or* • Anidulafungin 200 mg IV 1 time, then 100 mg IV daily, *or* • Posaconazole 200 mg PO qid, then, after condition improved, 400 mg PO bid.	• Potential for significant pharmacokinetic interactions between certain ARV agents and voriconazole; they should be used cautiously in these situations. Consider therapeutic drug monitoring and dosage adjustment if necessary.

Continued

TABLE 2 Treatment of AIDS-Associated Opportunistic Infections—cont'd

Opportunistic Infection	Preferred Therapy	Alternative Therapy	Other Comments
CMV disease	*CMV Retinitis Induction Therapy for Immediate Sight-Threatening Lesions (adjacent to the optic nerve or fovea)* • Consult ophthalmologist; ganciclovir implant no longer available: • Ganciclovir 5 mg/kg IV q12h for 14-21 days followed by Valganciclovir 900 mg PO bid. *For Small Peripheral Lesions:* • Valganciclovir 900 mg PO bid for 14-21 days. • One dose of intravitreal ganciclovir can be administered immediately after diagnosis until steady-state plasma ganciclovir concentration is achieved with oral valganciclovir. • *Chronic Maintenance (secondary prophylaxis):* • Valganciclovir 900 mg PO daily (for small peripheral lesion). *CMV Esophagitis or Colitis:* • Ganciclovir 5 mg/kg IV q12h; may switch to valganciclovir 900 mg PO q12h once patient can tolerate oral therapy.	*CMV Retinitis Induction Therapy:* • Ganciclovir 5 mg/kg IV q12h for 14-21 days, *or* • Foscarnet 90 mg/kg IV q12h or 60 mg q8h for 14-21 days, *or* • Cidofovir 5 mg/kg/wk IV for 2 wk; saline hydration before and after therapy and probenecid, 2 g PO 3 hours before dose, followed by 1 g PO 2 hours and 8 hours after the dose (total of 4 g). (Note: This regimen should be avoided in patients with sulfa allergy because of cross-hypersensitivity with probenecid.) • *Chronic Maintenance (secondary prophylaxis):* • Ganciclovir 5 mg/kg IV 5-7 times weekly, *or*	• The choice of therapy for CMV retinitis should be individualized, based on location and severity of the lesions, level of immunosuppression, and other factors (e.g., concomitant medications and ability to adhere to treatment). • The choice of chronic maintenance therapy (route of administration and drug choices) should be made in consultation with an ophthalmologist. Considerations should include the anatomic location of the retinal lesion, vision in the contralateral eye, the patients' immunologic and virologic status, and response to ART.
	• Duration: 21-42 days or until symptoms have resolved. • Maintenance therapy is usually not necessary but should be considered after relapses. *Well-Documented, Histologically Confirmed CMV Pneumonia:* • Experience for treating CMV pneumonitis in HIV patients is limited. Use of IV ganciclovir or IV foscarnet is reasonable (doses same as for CMV retinitis). • The optimal duration of therapy and the role of oral valganciclovir have not been established. • *CMV Neurologic Disease* • Note: Treatment should be initiated promptly. • Ganciclovir 5 mg/kg IV q12h + (foscarnet 90 mg/kg IV q12h or 60 mg/kg IV q8h) to stabilize disease and maximize response; continue until symptomatic improvement and resolution of neurologic symptoms. • The optimal duration of therapy and the role of oral valganciclovir have not been established.	• Foscarnet 90-120 mg/kg IV once daily, *or* • Cidofovir 5 mg/kg IV every other wk with saline hydration and probenecid as above. *CMV Esophagitis or Colitis:* • Foscarnet 90 mg/kg IV q12h or 60 mg/kg q8h for patients with treatment-limiting toxicities to ganciclovir or with ganciclovir resistance, *or* • Valganciclovir 900 mg PO q12h in milder disease and if able to tolerate PO therapy, *or* • For mild cases, if ART can be initiated without delay, consider withholding CMV therapy. • Duration: 21-42 days or until symptoms have resolved.	• Patients with CMV retinitis who discontinue maintenance therapy should undergo regular eye examinations for early detection of relapse IRU—optimally every 3 mo and then annually after immune reconstitution. • IRU may develop in the setting of immune reconstitution. • *Treatment of IRU:* • Periocular corticosteroid or short courses of systemic steroid. • Initial therapy in patients with CMV retinitis, esophagitis, colitis, and pneumonitis should include initiation or optimization of ART.
HSV disease	*Orolabial Lesions (for 5-10 days):* • Valacyclovir 1 g PO bid *or* • Famciclovir 500 mg PO bid *or* • Acyclovir 400 mg PO tid. *Initial or Recurrent Genital HSV (for 5-14 days):* • Valacyclovir 1 g PO bid, *or* • Famciclovir 500 mg PO bid, *or* • Acyclovir 400 mg PO tid. Severe Mucocutaneous HSV: • Initial therapy acyclovir 5 mg/kg IV q8h • After lesions begin to regress, change to PO therapy as previously. Continue until lesions are completely healed. • *Chronic Suppressive Therapy for Patients with Severe Recurrences of Genital Herpes or for Patients Who Want to Minimize Frequency of Recurrences:* • Valacyclovir 500 mg PO bid. • Famciclovir 500 mg PO bid. • Acyclovir 400 mg PO bid. • Continue indefinitely regardless of CD4 cell count.	*For Acyclovir-Resistant HSV* • *Preferred Therapy:* • Foscarnet 80-120 mg/kg/day IV in 2-3 divided doses until clinical response. • *Alternative Therapy* • IV cidofovir (dosage as in CMV retinitis), *or* • Topical trifluridine, *or* • Topical cidofovir, *or* • Topical imiquimod. • *Duration of Therapy:* • 21-28 days or longer.	• Patients with HSV infections can be treated with episodic therapy when symptomatic lesions occur, or with daily suppressive therapy to prevent recurrences. • Topical formulations of trifluridine and cidofovir are not commercially available. • Extemporaneous compounding of topical products can be prepared using trifluridine ophthalmic solution and the IV formulation of cidofovir.

TABLE 2 Treatment of AIDS-Associated Opportunistic Infections—cont'd

Opportunistic Infection	Preferred Therapy	Alternative Therapy	Other Comments
VZV disease	*Primary Varicella Infection (Chickenpox):* • *Uncomplicated Cases (for 5-7 days):* • Valacyclovir 1 g PO tid *or* • Famciclovir 500 mg PO tid. • *Severe or Complicated Cases:* • Acyclovir 10-15 mg/kg IV q8h for 7-10 days. • May switch to oral valacyclovir, famciclovir, or acyclovir after defervescence if no evidence of visceral involvement. *Herpes Zoster (Shingles) Acute Localized Dermatomal:* • For 7-10 days; consider longer duration if lesions are slow to resolve. • Valacyclovir 1 g PO tid *or* • Famciclovir 500 mg tid. *Extensive Cutaneous Lesion or Visceral Involvement:* • Acyclovir 10-15 mg/kg IV q8h until clinical improvement is evident. • May switch to PO therapy (valacyclovir, famciclovir, or acyclovir) after clinical improvement (i.e., when no new vesicle formation or improvement of signs and symptoms of visceral VZV), to complete a 10- to 14-day course. *Progressive Outer Retinal Necrosis:* • Ganciclovir 5 mg/kg + foscarnet 90 mg/kg IV q12h + ganciclovir 2 mg/0.05 ml ± foscarnet 1.2 mg/0.05 ml intravitreal injection twice weekly *or* • Initiate or optimize ART. *Acute Retinal Necrosis:* • Acyclovir 10 mg/kg IV q8h for 10-14 days, followed by valacyclovir 1 g PO tid for 6 wk.	*Primary Varicella Infection (Chickenpox):* • *Uncomplicated Cases (for 5-7 days):* • Acyclovir 800 mg PO 5 times/day. *Herpes Zoster (Shingles)* • Acute Localized Dermatomal: • For 7-10 days; consider longer duration if lesions are slow to resolve. • Acyclovir 800 mg PO 5 times/day.	• In managing VZV retinitis: Consultation with an ophthalmologist experienced in management of VZV retinitis is strongly recommended. • Duration of therapy for VZV retinitis is not well defined and should be determined based on clinical, virologic, immunologic, and ophthalmologic responses. • Optimization of ART is recommended for serious and difficult-to-treat VZV infections (e.g., retinitis, encephalitis).
Progressive multifocal leukoencephalopathy (JC virus infections)	• There is no specific antiviral therapy for JC virus infection. The main treatment approach is to reverse the immunosuppression caused by HIV. • Initiate ART immediately in ART-naïve patients. • Optimize ART in patients who develop PML in phase of HIV viremia on ART.	None.	• Corticosteroids may be used for PML-IRIS characterized by contrast enhancement, edema, or mass effect and with clinical deterioration.

AIDS, Acquired immunodeficiency syndrome; *ART,* antiretroviral therapy; *ARV,* antiretroviral; bid, twice a day; *CD4,* CD4 T lymphocyte cell; *CFU,* colony-forming unit; *CMV,* cytomegalovirus; *CNS,* central nervous system; *CSF,* cerebrospinal fluid; *CYP3A4*, cytochrome P-450 3A4; *DS,* double strength; *EMB*, ethambutol; *G6PD*, glucose-6-phosphate dehydrogenase; *HIV,* human immunodeficiency virus; *HSV*, herpes simplex virus; *ICU*, intensive care unit; *IM*, intramuscular; *INH*, isoniazid; *IRIS*, immune reconstitution inflammatory syndrome; *IRU,* immune recovery uveitis; *IV*, intravenous; *LP*, lumbar puncture; *MAC, Mycobacterium avium* complex; *NSAID*, nonsteroidal anti-inflammatory drugs; *PCP*, *Pneumocystis* pneumonia; *PI*, protease inhibitor; *PJP,* Pneumocystis jiroveci pneumonia; *PML*, progressive multifocal leukoencephalopathy; *PO*, oral; *PZA*, pyrazinamide; *qid*, four times a day; *RFB*, rifabutin; *RIF*, rifampin; *SS*, single strength; *TB,* tuberculosis; *tid*, three times daily; *tiw*, three times weekly; *TMP-SMX*, trimethoprim-sulfamethoxazole; *VZV*, varicella zoster virus. *Quality of Evidence for the Recommendation:*

I: One or more randomized trials with clinical outcomes and/or validated laboratory endpoints

II: One or more well-designed, nonrandomized trials or observational cohort studies with long-term clinical outcomes

III: Expert opinion

*Pyrimethamine and leucovorin doses are the same as for preferred therapy.

Acromegaly (PTG)

BASIC INFORMATION

DEFINITION

Acromegaly occurs due to hypersecretion of growth hormone (GH) or increased amounts of insulin-like growth factor I (IGF-I). It is a chronic debilitating disease with an insidious onset.

SYNONYM

Marie disease

ICD-10CM CODE
E22.0 Acromegaly and pituitary gigantism

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 3 to 4 new cases per 1 million persons annually
PREVALENCE: 50 to 60 cases per 1 million persons, with some estimates as high as 90 cases per 1 million persons
PREDOMINANT SEX: No sexual predominance
MEAN AGE AT DIAGNOSIS: Men: 40 yr; women: 45 yr
RISK FACTORS:

- Increased mortality rate, primarily from cardiovascular and respiratory causes
- Death in 50% of untreated patients by age 50 yr
- Increased prevalence of colon carcinoma and other malignancies (esophagus, stomach, melanoma, thyroid)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Coarse features resulting from growth of soft tissue
- Coarse, oily skin
- Macrocephaly
- Hands and feet that are spadelike (Fig. E1), fleshy, and moist
- Prognathism, which can give an underbite
- Carpal tunnel syndrome
- Excessive sweating
- Arthralgias and severe osteoarthritis
- History of increased hat, glove, and/or shoe size. Epiphyseal growth plates require sex hormones to close; therefore, prior to puberty, these patients will develop excessive longitudinal growth and gigantism
- Enlargement of nose, brow, and jaw (Fig. E2)
- Hypertension
- Muscle weakness and decreased exercise capacity
- Headache, often severe
- Diabetes mellitus
- Visual field defects
- Severe obstructive sleep apnea due to soft tissue swelling and macroglossia
- Cardiac abnormalities (cardiomyopathy, left ventricular hypertrophy, valvular heart disease, diastolic failure, arrhythmias)
- Tall stature
- Mild to moderate obesity
- Benign tumors (uterine myoma, skin tags, prostatic hypertrophy, colon polyps)

ETIOLOGY

Cause is usually a pituitary adenoma affecting the anterior lobe. In rare cases, extrapituitary production of either GH or GH-releasing hormone (GHRH) can also lead to clinical manifestations.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Ectopic production of GHRH from a carcinoid or other neuroendocrine tumor

- McCune-Albright syndrome
- Pachydermoperiostosis

WORKUP

- First screening test: Measure serum IGF-I level.
  1. Direct measurement of the GH level is not as useful because it is secreted in a pulsatile fashion and a random level may be falsely normal.
  2. Upper limits of a normal IGF-I level, depending on the assay: >380 ng/ml or 2.5 U/ml.
- Failure to suppress serum GH to less than 2 ng/ml after 100 g oral glucose is considered conclusive.
  1. Patients may show suppression of GH (paradoxic response).
  2. Patients will not suppress GH to ≤2 ng/ml (typical response in patients with acromegaly).
  3. GHRH level >300 ng/ml is indicative of an ectopic source of GHRH such as from carcinoid tumors of the pancreas or lung.

LABORATORY TESTS

- Elevated IGF-I level
- Elevated serum phosphate
- Elevated urine calcium

IMAGING STUDIES

- Imaging studies of choice: MRI of the pituitary and hypothalamus

FIG. E1 Acromegaly. Patient with acromegaly of hand on the left compared with normal-sized hand on the right. (James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

FIG. E2 Facial features of acromegaly with enlargement of brow, nose, and jaw. (Floege J, Johnson RJ, Feehally J [eds]: *Comprehensive clinical nephrology,* ed 4, 2010, Saunders.)

- CT of the pituitary and hypothalamus sometimes used initially

Rx TREATMENT

SURGERY

- Treatment of choice: Transsphenoidal microsurgical adenomectomy
- Surgical failure rate: Approximately 13.3% for microadenomas (tumors <10 mm) and 11.1% for macroadenomas (tumors ≥10 mm confined to the sella)
- Preoperative IGF-I level: Indicator of surgical outcome with higher levels associated with surgical failure

RADIOTHERAPY

- Stereotactic radiosurgery (gamma knife) can be used to increase the chance of remission or cure.
- Radiotherapy is usually reserved for tumor recurrence or persistence after surgery in patients with resistance to or intolerance of medical treatment.
- Major complication: Hypopituitarism, which may occur in up to 50% of patients; this complication is more likely in patients who had postoperative radiotherapy.

MEDICAL THERAPY

- Indicated when patients have not responded to surgical therapy (persistent elevation of IGF-1, abnormal glucose tolerance test), when surgery is contraindicated, and in patients waiting for the effects of radiotherapy to begin
- Somatostatin receptor ligands: Octreotide, lanreotide
  1. Important in the preoperative shrinkage of pituitary tumors and softening of adenomatous tissue.
  2. Pegvisomant is a GH receptor antagonist that has shown promising results in the treatment of acromegaly. It is generally used in patients with resistance to or intolerance of somatostatin analogs. It should be used in patients who do not have central compressive symptoms and those with resistant diabetes.
  3. Somatostatin agonist therapy has been shown to be effective as first-line medical therapy in reducing tumor volume. Dopamine receptor agonists (bromocriptine, cabergoline): Can be used in addition to somatostatin receptor ligands.

CHRONIC Rx

Combination of bromocriptine and octreotide may be synergistic, allowing a lower combination dosage than either alone.

DISPOSITION

- Patients receiving radiotherapy need long-term follow-up to monitor the potential development of hypopituitarism.
- Continuation of medical therapy should be based on the normalization of IGF-I levels.

Actinic Keratosis

BASIC INFORMATION

DEFINITION

Actinic keratoses (AKs) are common skin lesions usually presenting as multiple erythematous or yellow-brown, dry, scaly lesions in the middle aged or elderly.

SYNONYMS

Solar keratosis
Senile keratosis
AK

ICD-10CM CODE
L57.0 Actinic keratosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: In regions of the northern hemisphere, 11% to 25% of adults have a minimum of one AK. In regions closer to the equator, 40% to 60% of adults have a minimum of one AK.
PEAK INCIDENCE: The risk of squamous cell carcinoma in patients with AK is 6% to 10%. Risk factors associated with increased risk of invasive squamous cell carcinoma arising from actinic keratosis include lesion location (lip, ear, extremities), lesion characteristics (ulceration, induration, hyperkeratotic, proliferative, inflamed, bleeding, large surface area and depth), pigmentation (any rapid changes in presentation, presence of multiple lesions, evidence of greater ultraviolet [UV]-induced skin damage), presence of concomitant illness (lymphoma, leukemia), and use of concomitant medications (immunosuppressive agents, medications that increase sun sensitivity).[1]
PREVALENCE:
- In the United States, 58.08 million/yr.
- Highest prevalence in those with fair complexions with high sun exposure.
- Approximately 60% of predisposed individuals older than 40 yr will have one AK.
- Caucasians' risk increases with age: At age 20 to 29 prevalence is <10%, at age 80 to 89 prevalence is approximately 75%.

PREDOMINANT SEX AND AGE: Males > females, age 65 to 74. Occurs most in those with fair complexions who burn rather than tan following sun exposure.
GENETICS: There is increased frequency of nonmelanoma skin cancers connected to squamous cell cancers with the genetic conditions xeroderma pigmentosum, oculocutaneous albinism, epidermodysplasia verruciformis, dystrophic epidermolysis bullosa, Ferguson-Smith syndrome, and Muir-Torre syndrome.
RISK FACTORS:
- Immunosuppression, exposure to UV light, ionizing radiation, arsenic, human papillomavirus, cigarette smoke, chronic ulcers, thermal burns, chronic discoid lupus erythematosus, and nonhealing wounds
- Lichen planus, lichen sclerosis, linear and classic porokeratosis, and disseminated superficial actinic porokeratosis
- Age, gender, skin color, and mutations in p53 tumor suppressor gene

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Typical lesions occur on sun-damaged skin, usually on the face and neck and the dorsal aspects of hands and forearms (Fig. E1).
- Advanced lesions are characterized by a hard, spiky scale and usually measure 1 cm in diameter or less. Early lesions manifest with redness and minimal scale. With progression, scales become thicker and yellow and may resemble a small squamous cell carcinoma. On examinations, lesions are rough and gritty.
- The surrounding skin frequently shows additional features of sun damage, including atrophy, pigment changes, and telangiectasia.
- Classifications:
  1. Hypertrophic AK with a cutaneous horn: Biopsy is necessary to distinguish the cutaneous horn from squamous cell carcinoma, seborrheic keratosis, verruca, and trichilemmoma and basal cell carcinoma. Hypertrophic AK has appearance of thick, scaling skin elevations.
  2. Lichenoid AK: Most commonly found on the torso and upper extremities. Must be distinguished from BCC due to pink and pearly characteristics.
  3. Proliferative AK: Often reappear after treatment and are characterized by a diameter >1 cm. Often occurs in same differential as Bowen's disease or SCC.
  4. Spreading pigmented AK: Must be biopsied to distinguish from lentigo maligna–type melanoma in situ as well as solar lentigo.
  5. Actinic cheilitis: Characterized by red and sometimes abrasive lesions around the border of the lips and skin.

ETIOLOGY

- Sun exposure, ionizing radiation
- Arsenic, polycyclic hydrocarbon exposure

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Heavily pigmented variants may be clinically mistaken for lentigo maligna
- Basal cell or squamous cell carcinoma
- Seborrheic keratosis
- Eczema
- Bowen disease (intraepithelial carcinoma)
- Wart
- Lichenoid keratosis
- Cutaneous lupus

WORKUP

History, physical, and lesion biopsy. Include risk assessment and family or personal history of skin cancers or previous skin lesions.

LABORATORY TESTS

- Skin biopsy in recurrent lesions or when diagnosis is unclear to rule out squamous cell or basal cell carcinoma.
- Microscopy reveals atypical keratinocytes in the lower epidermis basal layers. They are enlarged and often lack normal polarity. The thickness of the epidermis can be compromised with a distribution of atrophic to hyperplastic. Abnormal keratinocytes can cause parakeratosis of the overlying stratum corneum. Visible signs of an alternating orthohyperkeratosis can overlie the spared epithelium, causing the signature "flag sign." Additionally, there is a distinct margin between normal epidermis and the region of AK at lateral edges. Histologic subtypes are hypertrophic, acantholytic, lichenoid, and bowenoid, which are characterized by a thick stratum corneum, lack of intracellular cohesion, presence of lymphocytic infiltrate in papillary dermis, and either lack of association of adnexal epithelium or full epithelial thickness with pleomorphic keratinocytes, respectively.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Cryotherapy with liquid nitrogen: Treatment of choice for most isolated, superficial AKs
- Carbon dioxide laser
- Dermabrasion
- Chemical peel
- Curettage
- Excision
- Photodynamic therapy with 5-aminolevulinic acid and blue light (16 minutes) or methyl aminolevulinate and red light (7 to 10 minutes)

ACUTE GENERAL Rx

- Topical 5-fluorouracil (5-FU) bid for 4 to 6 weeks. Table E1 summarizes guidelines for duration of 5-FU therapy according to site.
- Topical diclofenac sodium 3% gel bid for 60 to 90 days.
- Topical imiquimod 5% cream bid for 3 to 4 months.
- Oral retinoids.
- Topical ingenol mebutate 0.05% gel applied for 2 days with exception of face—or 0.015% for 3 days. Combination medication therapy or nonpharmacologic therapy with pharmacologic therapy is common (especially in refractory AK).
- A 10% nanoemulsion gel formulation of the porphyrin-based photosensitizers aminolevulinic acid (Ameluz) is available for use in combination with a narrow-band red light photodynamic therapy (PDT) lamp (BF-RhodoLED) for mild to moderate severity AK on face and scalp.
- Table E2 describes preparations for treatment of actinic keratosis.

[1]Rigel DS, Stein Goold LF: The importance of early diagnosis and treatment of actinic keratosis. *J Am Acad Dermatol* 68:S20-27, 2013.

FIG. E1 Actinic keratosis (AKs). A, Multiple AKs on the face of an elderly woman with fair complexion, blue eyes, and moderate to severe photodamage; the AKs vary in size from a few millimeters to more than a centimeter. On the left forehead, the red nodule with slight scale-crust represents a well-differentiated SCC. **B,** Pink-colored atrophic AK with minimal scale on the forehead. **C,** Multiple AKs on the bald scalp, some of which are hyperkeratotic; the area of hypopigmentation represents a site of previous treatment and due to the field defect, recurrence at the edge is commonly observed. **D,** Multiple, large hypertrophic AKs on the skin of an elderly woman; note the thick scale. (From Bolognia J: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier. **B,** Courtesy, Iris Zalaudek, MD; **D,** Courtesy, Jean L Bolognia, MD.)

TABLE E1 Guidelines for Duration of 5-Fluorouracil Therapy According to Site

Site	Early Signs of Inflammation (days)	Duration of Treatment (weeks)
Face, lips	3-5	2-4
Scalp	4-7	3-5
Neck	4-7	2-4
Arms, hands, legs	10-14	4-8
Back	10-14	4-6
Chest	10-14	4-6

From Habif TP: *Clinical dermatology,* ed 6, Philadelphia, 2016, Elsevier.

TABLE E2 Preparations for Treatment of Actinic Keratosis

Product	Active Ingredient	Packaging
Carac	0.5% fluorouracil	30-g cream
Efudex	2% fluorouracil 5% fluorouracil 5% fluorouracil	10-ml liquid 10-ml liquid 25-g cream
Fluoroplex	1% fluorouracil 1% fluorouracil	30-ml solution, 30-g cream
Aldara	5% imiquimod	Cream—box of 12 or 24 packets
Zyclara	2.5%, 3.75% imiquimod	Cream—box of 28 packets, 7.5- and 15-g pump bottle

From Habif TP: *Clinical dermatology,* ed 6, Philadelphia, 2016, Elsevier.

REFERRAL

To a dermatologist for biopsy of suspicious lesions, then follow up minimum annually or semiannually

PEARLS & CONSIDERATIONS

COMMENTS

- AKs are of particular importance because they are a sensitive indicator of exposure to UV light and strongly predict the likelihood of developing cutaneous squamous cell carcinoma.
- The cumulative probability of development of invasive squamous cell carcinoma in patients with 10 or more AKs has been estimated at 14% in a 5-yr period.
- It is estimated that up to 10% of AKs tend to progress to invasive carcinoma. Factors associated with increased risk of invasive squamous cell carcinoma include presence of multiple lesions, large surface area and depth, hyperkeratotic proliferative lesions, location on lip, ear, and extremities and concomitant illness (leukemia, lymphoma), and use of immunosuppressive agents and agents that increase sun sensitivity.

PREVENTION

- Avoidance of sun exposure or tanning booths
- Use of sunscreens
- Routine self-skin examinations
- Pharmaceutical prevention:
  1. Mild to moderate reduction of AK formation has been documented with the use of topical tretinoin, isotretinoin, and arotinoid methylsulfonyl.
  2. Nicotinamide as preventive rx has been documented to have a possible 30% relative reduction in AK.
  3. Decreased AK development has been documented with the use of high-SPF sunscreens.
  4. Decreased AK development has been seen in patients with xeroderma pigmentosum who used DNA repair enzymes.
  5. Decreased AK formation has been documented in high-risk patients (specifically those with xeroderma pigmentosum, nevoid basal cell carcinoma syndrome, and organ transplantation recipients) with the use of oral retinoids.

BASIC INFORMATION

DEFINITION

Actinomycosis is an indolent, slowly progressive infection caused by anaerobic or microaerophilic bacteria, mostly from the genus *Actinomyces,* that normally colonize the mouth, vagina, and colon. Actinomycosis is characterized by the formation of painful abscesses, soft tissue infiltration, and draining sinuses.

SYNONYMS

Actinomyces infection
Lumpy jaw

ICD-10CM CODES

A42.9	Actinomycosis, unspecified
A42.0	Pulmonary actinomycosis
A42.1	Abdominal actinomycosis
A42.2	Cervicofacial actinomycosis
A42.89	Other forms of actinomycosis

EPIDEMIOLOGY & DEMOGRAPHICS

GEOGRAPHIC DISTRIBUTION:

- Actinomycosis infections are seen worldwide.
- Commonly found as normal flora of the oral cavity (within gingival crevices, tonsillar crypts, periodontal pockets, dental plaques, and carious teeth), pharynx, tracheobronchial tree, gastrointestinal tract, and female urogenital tract. However, actinomyces are not found in the environment.

INCIDENCE:

- 1:300,000 in 1970s but now less with better oral hygiene and antibiotic use
- Males infected more often than females (3:1)
- Can occur at any age but commonly seen in midlife

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Actinomycosis can affect any organ. Although not typically considered as opportunistic pathogens, *Actinomyces* species capitalize on tissue injury or mucosal breach to invade adjacent structures in the head and neck regions. As a result, dental infections and oromaxillofacial trauma are common antecedent events. Characteristic manifestations include:

- Cervicofacial disease (most common site with 60% of cases):
  1. Occurs in the setting of poor dental hygiene, recent dental surgery, or minor oral trauma.
  2. Painful soft tissue swelling (Fig. E1) commonly seen at the angle of the mandible.
  3. Fever, chills, and weight loss.
  4. Trismus.
  5. Soft tissue facial infection with sinus tract or fistula formation.
- Thoracic disease:
  1. Can involve the lungs, pleura, mediastinum, or chest wall.
  2. Presumed secondary to aspiration of *Actinomyces* organisms in patients with poor oral hygiene.
  3. Fever, cough, weight loss, and pleuritic chest pains are common symptoms.
  4. Signs of pneumonia or pleural effusion may be present.
  5. With extension beyond the lungs to mediastinal structures and the chest wall, signs and symptoms of pericarditis, empyema, chest wall sinus drainage, and tracheoesophageal fistula can all occur (Fig. E2).
- Abdominal disease:
  1. Occurs most commonly after appendectomy, perforated bowel, diverticulitis, or surgery to the gastrointestinal tract.
  2. Lesions develop most commonly in the ileocecal valve, causing abdominal pain, fever, weight loss, and a palpable mass.
  3. Extension may occur to the liver, causing jaundice and abscess formation.
  4. Sinus tracts to the abdominal wall can occur.
- Pelvic disease:
  1. Commonly occurs by extension from abdominal disease of the ileocecal valve to the right adnexa (80% of cases).
  2. Endometritis.

ETIOLOGY

- Actinomycosis is most commonly caused by *Actinomyces israelii.* Other causes are *A. naeslundii, A. odontolyticus, A. viscosus,* and *A. meyeri.*
- *Actinomyces* are gram-positive, non–spore-forming, filamentous, anaerobic or microaerophilic rods.
- Actinomycosis infections are polymicrobial, usually associated with *Eikenella corrodens,* and *Streptococcus, Bacteroides, Enterococcus,* and *Fusobacterium* spp.

FIG. E1 Actinomycosis of the jaw, observed at Letterman General Hospital, San Francisco, in a sergeant who had punctured the floor of his mouth while picking his teeth. (Office of Medical History, Office of the Surgeon General, U.S. Army; from Goldman L, Schaefer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.)

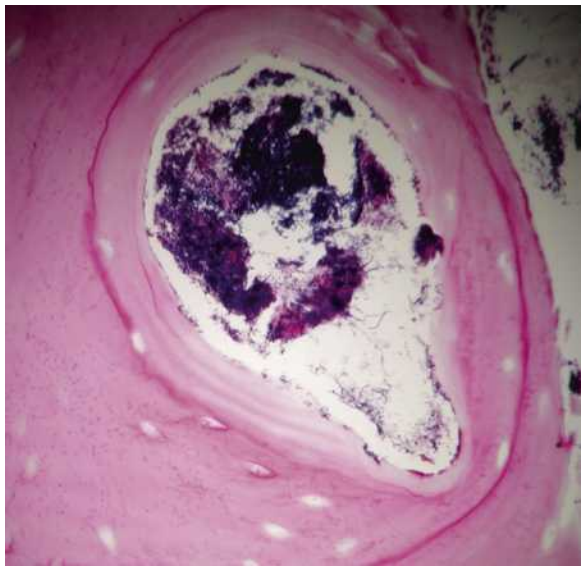

FIG. E2 Maxillary osteomyelitis due to *Actinomyces viscosus* in a patient with multiple myeloma who was treated with bisphosphonates and underwent several dental procedures. Pictured is a sulfur granule within necrotic maxilla. (From Bennett JE, Dolin R, Blaser MJ: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases*, ed 8, Philadelphia, 2015, Saunders.)

- Infects individuals only after entry into disrupted mucosa or tissue injury.
- Predisposing conditions include diabetes mellitus, malnutrition, and immunosuppression.

Dx DIAGNOSIS

Isolating the bacteria in the proper clinical setting makes the diagnosis of actinomycosis.

DIFFERENTIAL DIAGNOSIS

- Cervicofacial disease: Odontogenic abscesses, brachial cleft cyst
- Pulmonary disease: Nocardiosis, botryomycosis, chromomycosis, fungal disease of the lung, tuberculosis
- Intestinal disease: Intestinal tuberculosis, ameboma, Crohn disease, colon cancer
- Pelvic disease: Chronic pelvic inflammatory disease, Crohn disease
- CNS disease: Other forms of brain abscess, brain tumors, toxoplasmosis, intracranial hematoma

WORKUP

The workup includes obtaining specimens either by aspirating abscesses, excising sinus tracts, or tissue biopsies. All specimens should be set up to culture anaerobic bacteria and held at least 5 to 7 days.

LABORATORY TESTS

- Isolating "sulfur granules" from tissue specimens or draining sinuses confirms the diagnosis of actinomycosis. *Actinomyces* are noted for forming characteristic sulfur granules in infected tissue but not in vitro. The term *sulfur granule* is a misnomer, reflecting only the yellow color of the granule in pus, because the granules are not composed of any sulfur at all.
  1. Sulfur granules are nests of *Actinomyces* species. Sulfur granules may be macroscopic or microscopic.
  2. Sulfur granules are crushed and stained for identification of *Actinomyces* organisms and may take up to 3 wk to grow in culture media.

IMAGING STUDIES

Imaging studies are useful adjunctive tests in localizing the site and spread of infection.

- Chest x-ray examination.
- CT scan of the head, chest, abdomen, and pelvic areas is useful.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Incision and drainage of abscesses
- Excision of sinus tract

ACUTE GENERAL Rx

- Ampicillin 50 mg/kg/day in 3 to 4 divided doses x 4 to 6 wk; then Pen VK 2 to 4 g/day PO x 4 to 6 wk. In place of ampicillin, can also use penicillin 3 to 4 million units IV q4h for 4 to 6 wk.
- In penicillin-allergic patients, erythromycin (500 to 1000 mg IV q6h), tetracycline or doxycycline (100 mg IV q12h), and clindamycin (900 mg IV q8h) are reasonable alternatives. Other alternatives include ceftriaxone, imipenem, and piperacillin/tazobactam.
- Avoid use of metronidazole, aminoglycosides, oxacillin, and cephalexin.

CHRONIC Rx

- After 4 to 6 wk IV ampicillin (2 g IV q 4 to 6 hr) or penicillin (10 to 20 million units per day divided q 4 to 6 hr), can switch to oral penicillin V 500 mg PO qid for 4 to 6 wk. Longer treatment with 6 to 12 months of antibiotic therapy is often necessary in some cases.
- Other available oral agents are erythromycin, doxycycline, and clindamycin.
- Treatment of associated microorganisms is not needed.
- Surgical debridement for complicated abscesses, fibrous tracts, necrotic tissues, fistulas, and bone involvement may also be required.

DISPOSITION

- Clinical actinomycosis, if not treated, spreads to contiguous tissues and structures ignoring tissue planes. Hematogenous spread, although possible, is rare.
- Actinomycosis is very sensitive to antibiotics but requires chronic long-term treatment to prevent relapse.

REFERRAL

If the diagnosis of actinomycosis is suspected, consultation with an infectious disease specialist is suggested. General surgical consultation for excision of sinus tracts and abscess incision and drainage is recommended.

! PEARLS & CONSIDERATIONS

COMMENTS

- There is no person-to-person transmission of *Actinomyces.*
- Isolation of the organism in an asymptomatic individual does not mean the person has actinomycosis. Active symptoms must be present to make the diagnosis.
- Pelvic actinomycosis has been associated with use of an intrauterine device (IUD).
- Actinomycosis can also involve the CNS, causing multiple brain abscesses.
- HIV, solid organ transplantation of lungs or kidneys, biologic agents like infliximab, and acute lymphoblastic leukemia treated with chemotherapy are other risk factors.

Acute Bronchitis PTG

BASIC INFORMATION

DEFINITION

Acute bronchitis is a self-limited inflammation of trachea and bronchi.

SYNONYM

Chest cold

ICD-10CM CODE
J20.9 Acute bronchitis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Highest incidence in smokers, older adults, and young children and during winter months.
- In the U.S. there are nearly 30 million ambulatory visits annually for cough, leading to more than 12 million diagnoses of "bronchitis."
- Acute lower respiratory tract infection is the most common condition treated in primary care.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- In most cases, acute bronchitis begins with signs and symptoms typical of the common cold syndrome (nasal congestion, sore throat), followed shortly by the onset of cough
- Cough, usually worse in the morning, often productive; mainly caused by transient bronchial hyperresponsiveness
- Low-grade fever
- Substernal discomfort worsened by coughing
- Postnasal drip, pharyngeal injection
- Rhonchi that may clear after cough, occasional wheezing
- Various host factors (age, immune status, smoking, underlying medical conditions) can influence illness severity and clinical presentation
- In mild cases, the illness lasts only 7 to 10 days, whereas in others, cough may persist for up to 3 weeks or longer

ETIOLOGY

- Viral infections are the leading cause of bronchitis (rhinovirus, influenza virus, adenovirus, respiratory syncytial virus)
- Atypical organisms *(Mycoplasma, Chlamydia pneumoniae)*
- Bacterial infections *(Bordetella pertussis, Haemophilus influenzae, Moraxella, Streptococcus pneumoniae)*
- Table 1 summarizes viral and bacterial causes of acute bronchitis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pneumonia
- Asthma
- Sinusitis
- Bronchiolitis
- Aspiration
- Cystic fibrosis
- Pharyngitis
- Cough secondary to medications
- Neoplasm (elderly patients)
- Influenza
- Allergic aspergillosis
- Gastroesophageal reflux disease
- Congestive heart failure (in elderly patients)
- Bronchogenic neoplasm

WORKUP

Seldom necessary (e.g., to rule out pneumonia, neoplasm)

LABORATORY TESTS

Laboratory tests are generally not necessary.

IMAGING STUDIES

Chest x-ray is usually reserved for patients with suspected pneumonia, influenza, or underlying chronic obstructive pulmonary disease (COPD) and no improvement with therapy.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of tobacco and other pulmonary irritants
- Increased fluid intake
- Use of vaporizer to increase room humidity

TABLE 1 Viral and Bacterial Causes of Acute Bronchitis

Pathogen	Seasonality	Comments
Influenza viruses	Winter	Local epidemics last 6-8 wk during which clinical illness of cough and fever has high predictive value; laboratory diagnosis readily available; early neuraminidase inhibitor therapy effective
Rhinoviruses	Fall and spring	Most frequent cause of common cold syndrome; immunity is serotype specific
Coronaviruses	Winter to spring	Cause common cold syndrome; newer strains are difficult to culture and require RT-PCR for diagnosis
Adenoviruses	Yr round, winter epidemics	High attack rates in closed populations such as persons living in military barracks or college dormitories; serotype-specific immunity
Respiratory syncytial virus (RSV)	Late fall to early spring	Attack rates approach 75% in neonates, 3%-5% in adults; associated with wheezing in all age groups; rapid antigen test accurate in children but requires culture or RT-PCR to diagnose in adults
Human metapneumovirus (hMPV)	Winter to early spring	Associated with wheezing in adults and in infants; difficult to isolate in tissue culture and often requires RT-PCR
Parainfluenza viruses	Fall to winter	Similar to RSV and hMPV, parainfluenza viruses primarily pediatric pathogens but can cause severe acute disease in some adults
Measles virus	Yr round	Can cause respiratory disease in malnourished children; illness causes transient immune suppression
Mycoplasma pneumoniae	Yr round, fall outbreaks	Long incubation period (10-21 days) results in staggered epidemic pattern in families; nonproductive persistent cough typical; diagnosed by IgM serology; treated with macrolide, quinolone, or tetracycline antibiotics
Chlamydia pneumoniae	Yr round	Associated with sinusitis; diagnosis by RT-PCR not readily available
Bordetella pertussis	Yr round	Severe illness in nonimmunized children; illness milder in partially immune adults; can be associated with prolonged cough; adults often reservoir for epidemics; early therapy with antibiotics can reduce spread

RT-PCR, Reverse-transcriptase polymerase chain reaction.
From Bennett JE, Dolin R, Blaser MJ: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Saunders.

ACUTE GENERAL Rx

- Therapy is generally symptomatic and directed at relief of cough and wheezing.
- Inhaled bronchodilators (e.g., albuterol, metaproterenol) PRN for 1 to 2 wk in patients with wheezing or troublesome cough. Inhaled albuterol has been proven effective in reducing the duration of cough in adults with uncomplicated acute bronchitis.
- Cough suppression with dextromethorphan and guaifenesin is commonly recommended; addition of codeine for cough suppression if cough is severe and is significantly interrupting patient's sleep pattern.
- Use of antibiotics (TMP-SMX, amoxicillin, doxycycline, cefuroxime) for acute bronchitis is generally not indicated; should be considered only in patients with concomitant COPD and purulent sputum or in patients with suspected pertussis. In the few cases of acute bronchitis caused by *B. pertussis* or atypical bacteria such as *C. pneumoniae* or *Mycoplasma pneumoniae,* early use of macrolide antibiotics is reasonable.
- Antibiotics are overused in patients with acute bronchitis (70% to 90% of office visits for acute bronchitis result in treatment with antibiotics); this practice pattern is contributing to increases in resistant organisms.
- Trials have shown that there are no significant differences in patients receiving antibiotics compared with those receiving placebo in overall clinical improvements or limitations in work or other activities. There was a significant increase in adverse effects in the antibiotic group, particularly gastrointestinal symptoms.[1]

CHRONIC Rx

Avoidance of tobacco and other pulmonary irritants

DISPOSITION

- Complete recovery within 7 to 10 days in most patients.
- Patients should be informed to expect to have a cough for 10 to 14 days after the visit.

REFERRAL

For pulmonary function testing only in patients with recurrent bronchitis and suspected underlying pulmonary disease

PEARLS & CONSIDERATIONS

COMMENTS

- Patients are more likely to receive prescriptions for antibiotics from mid- or late-career physicians with high patient volumes and from physicians who were trained outside of Canada or the U.S.[2] Intervention studies reveal that patient and physician education are effective in reducing the use of antibiotic therapy. No offer or delayed offer of antibiotics for acute uncomplicated lower respiratory tract infection is acceptable, is associated with little difference in symptom resolution, and is likely to reduce antibiotic use and beliefs in the effectiveness of antibiotics.
- It is helpful to refer to acute bronchitis as a "chest cold." Patients should be informed that antibiotics are probably not going to be beneficial and may result in significant side effects.

Acute Bronchitis (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

[1] Smith SM, Smucny J, Fahey T: Antibiotics for acute bronchitis, *JAMA* 312:2678, 2014.

[2] Silverman M et al: Antibiotic prescribing for nonbacterial acute upper respiratory infections in elderly persons. *Ann Intern Med* 166:765-774, 2017.

BASIC INFORMATION

DEFINITION

Ogilvie syndrome is characterized by acute massive dilation of the cecum and right colon, with occasional extension to the rectum, in the absence of any mechanical obstruction. Oftentimes, acute colonic pseudo-obstruction occurs after surgery, and it can also be seen in patients with significant underlying medical illnesses. Cecal diameter on abdominal radiographs greater than 12 cm is considered to be the threshold where spontaneous perforation becomes more likely. Medications such as opioids and anticholinergics also contribute to the development of this condition.

SYNONYMS

Ogilvie syndrome
ACPO
Acute megacolon

ICD-10CM CODE
K56.6 Other and unspecified intestinal obstruction

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Unknown
PREVALENCE: Unknown
PREDOMINANT SEX AND AGE: Although recent data is lacking, data from a retrospective study in 1986 suggested a male predominance with average age of onset in the sixth decade. In general, prevalence is thought to increase with age, although affected females tend to be younger because of the association of acute colonic pseudo-obstruction with obstetric complications.
PEAK INCIDENCE: Unknown
RISK FACTORS: Elderly patients seem to be at greatest risk. Other risk factors include significant underlying medical illness, sepsis, electrolyte abnormalities, recent cardiac events, certain medications (opioids, anticholinergics, phenothiazines, benzodiazepines, calcium channel blockers, chemotherapeutic agents, and antiparkinsonian agents), and postoperative patients (Box E1).
GENETICS: None

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute abdominal distention and crampy abdominal pain are the most common symptoms associated with Ogilvie syndrome. The distention can be so severe that it may lead to labored breathing. Nausea, vomiting, obstipation, constipation, and, paradoxically, diarrhea, can also be seen but are not consistently present. It has been estimated that 40% to 50% of patients continue to pass flatus.
- Physical exam is significant for massive abdominal distention that is tympanic to percussion and varying degrees of abdominal pain or discomfort are also present. Hypoactive or hyperactive bowel sounds are often described. Peritoneal signs are often absent early on but their presence is concerning for imminent perforation.

ETIOLOGY

Colonic motor and secretory functions are mediated by the autonomic nervous system with the ascending colon receiving parasympathetic innervation from the medulla oblongata via the vagus nerve, which increases gut motility, and sympathetic innervation from the spinal cord, which decreases motility. It is thought that parasympathetic dysfunction is the main driving force that leads to Ogilvie syndrome but the exact mechanism is unknown.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Mechanical obstruction
- Volvulus
- Intussusception
- Ileus
- Toxic megacolon

BOX E1 Clinical Factors Predisposing to Ogilvie Syndrome or Acute Colonic Pseudo-Obstruction

Cardiovascular
- Heart failure, stroke
- Gut ischemia

Critical illness
- Severe sepsis
- Acute pancreatitis
- Shock or hypoxemia

Postoperative state or trauma
- Intestinal manipulation
- Peritonitis
- Immobility and dehydration
- Vertebral, pelvic or hip fracture/surgery
- Retroperitoneal hematoma

Metabolic factors
- Hypokalemia and hyperglycemia
- Hypothyroidism, diabetes mellitus
- Liver or renal failure
- Amyloidosis

Drugs
- α-Adrenergic agonists, dopamine
- Clonidine and dexmedetomidine
- Opioids
- Anticholinergics, calcium channel antagonists
- Antipsychotics
- Antidepressants
- High-dose phosphodiesterase inhibitors

Gastrointestinal infections
- Cytomegalovirus, herpes zoster
- Tuberculosis

Neurologic
- Transection of the spinal cord
- Low spinal cord disease
- Parkinson disease

Obstetric
- Caesarean section
- Normal delivery

From Vincent JL et al: *Textbook of critical care*, ed 6, Philadelphia, 2011, Saunders.

WORKUP

- History should be focused on the perceived progression of distention and timing of most recent flatus or bowel movement as well as determining any predisposing factors such as recent surgery, severe illness, and recent medication changes.
- Physical examination should focus on assessing the degree of abdominal distention and percussion to evaluate for tympanic sounds, which is a hallmark of Ogilvie syndrome. Serial abdominal exams should be performed to ensure no peritoneal signs such a rebound, guarding, or rigidity that would suggest impending or frank perforation.
- Laboratory evaluation should center on metabolic abnormalities as well as lactic acidosis and leukocytosis, which can both be used as a barometer of the severity of the patient's underlying illness as well as a marker for impending perforation.
- Imaging of the abdomen with plain radiograph is important for tracking degree of distention.

LABORATORY TESTS

- Metabolic abnormalities such as hypocalcemia, hypomagnesemia, and hypokalemia are commonly present and should be corrected accordingly.
- Leukocytosis as well as lactic acidosis are markers of underlying disease and impending perforation.

IMAGING STUDIES

- Plain and upright abdominal radiographs (Fig. E1) are important to establish degree of colonic distention, which often involves

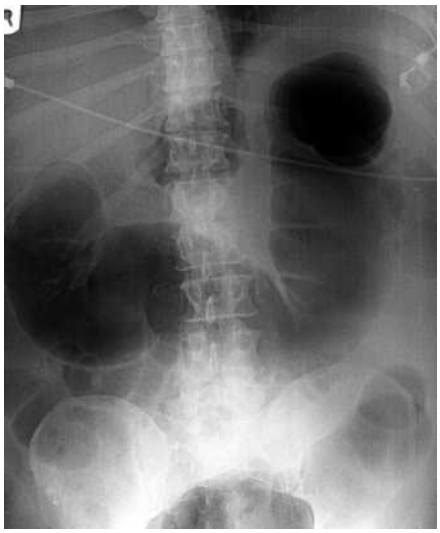

FIG. E1 Plain abdominal radiograph of patient with Ogilvie syndrome 11 days after surgery for ruptured aneurysm of abdominal aorta. Dilation (probably due to ischemia) is present in both right and left colon. Syndrome resolved with vasodilators and intravenous neostigmine. (From Vincent JL et al: *Textbook of critical care*, ed 6, Philadelphia, 2011, Saunders.)

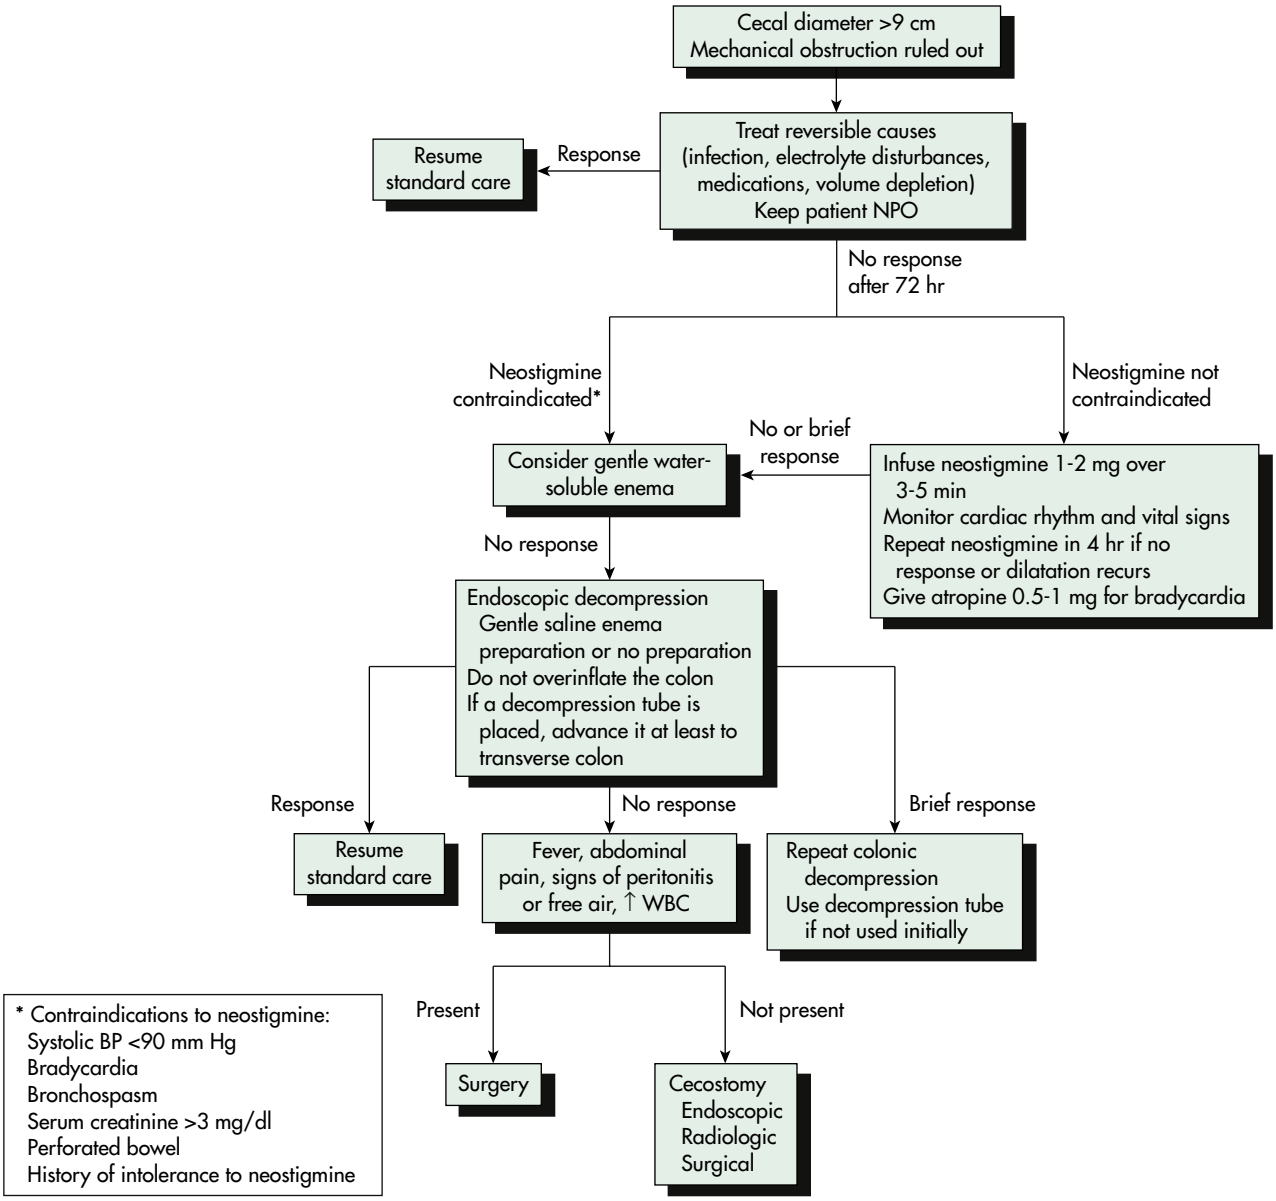

FIG. E2 Algorithm for the treatment of acute colonic pseudo-obstruction. *BP,* Blood pressure; *NPO*, nothing by mouth; *WBC*, white blood cell. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fortran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.)

the cecum but can also extend to the splenic flexure or rectum. Haustral markings are usually normal.

- CT scan or enema-enhanced radiograph is imperative to confirm the diagnosis and rule out underlying mechanical obstruction.

Rx TREATMENT

The goals of treatment are to decompress the colon in order to relieve the patient's abdominal discomfort and also mitigate the risk of developing intestinal ischemia or frank perforation. Fig. E2 illustrates an algorithm for the treatment of acute colonic pseudo-obstruction.

NONPHARMACOLOGIC THERAPY

- Supportive care with plain radiographs every 12 to 24 hr, serial abdominal exams, elimination of potential precipitants (medications, treatment of underlying medical illness), correction of electrolyte abnormalities, restricting PO intake, gastric decompression with nasogastric tube tube to intermittent suction, rectal decompression with rectal tube attached to gravity, IV fluids, encouraging ambulation if possible, and alternating the patient in bed between right and left lateral decubitus as well as prone positioning with hips elevated are all appropriate nonpharmacologic approaches that can be made initially in the absence of colonic distention >12 cm or significant abdominal pain.
- Colonoscopic decompression with or without placement of a decompression tube is often the next step in management, although use of this technique remains controversial as some studies indicate that the majority of patients spontaneously resolve within 48 hr. The risk of complication with colonoscopy in this setting is 3%, with a quoted death rate of 1%. Other studies suggest a success rate of 69% to 90% with colonoscopic decompression.
- Colonoscopic decompression is indicated when supportive measures fail, there is clinical deterioration, or colonic diameter is between 11 and 13 cm. Placement of a decompression tube at the time of colonoscopy is thought to reduce the need for repeat colonoscopic decompression, which is required in about 40% of cases, but no trials have been done to compare rates of repeat decompression with and without decompression tube placement.
- Alternative minimally invasive options which are usually reserved for failed colonoscopic decompression include percutaneous tube cecostomy performed under radiologic

guidance and percutaneous endoscopic colostomy, which are both techniques that grant percutaneous access to the colon for both decompression and irrigation to promote transit.
- Surgical management is reserved for those who have failed minimally invasive approaches or for patients with peritonitis or perforation. Surgical cecostomy tube or right hemicolectomy can be performed in the absence of perforation whereas ileostomy, colectomy, and Hartmann procedure can be performed in patients who have perforated or who have significant ischemia.

ACUTE GENERAL Rx

- Neostigmine is an IV anticholinesterase inhibitor that induces rapid colonic decompression in 80% to 100% of appropriate candidates with a median response rate of 4 min at a starting dose of 2 mg, but requires close cardiovascular monitoring at the time of its administration and has several contraindications. Dose adjustments are required in chronic kidney disease and caution should be used in patients who have bradyarrhythmias, recent myocardial infarction, beta-blocker use, and asthma. Atropine should be made available at bedside and administration of glycopyrrolate, an anticholinergic agent, should be considered to decrease the risk of bradycardia and bronchoconstriction.
- Methylnaltrexone, a peripherally acting opiate receptor antagonist, can also be considered in cases thought to be precipitated by opioids but little data supports its use at this time.

CHRONIC Rx

None

COMPLEMENTARY AND ALTERNATIVE MEDICINE

None

DISPOSITION

- Close inpatient monitoring is indicated until there is return of spontaneous bowel function and resolution of abdominal distention.

BOX E2 Strategies to Prevent Ogilvie Syndrome in the Critically Ill

- Early resuscitation of the circulation
- Minimizing prolonged infusion of high doses of α-adrenergic drugs
- Minimizing the use of dopamine
- Minimizing the prolonged use of opioids
- Use of thoracic epidural anesthesia
- Minimally invasive or laparoscopic surgery
- Selective decontamination of the digestive tract
- Avoiding antibiotics that disrupt growth of anaerobic fecal bacteria
- Early oral or enteral feeding
- Avoidance of proton pump inhibitors
- Early mobilization and ambulation
- Promoting timely defecation with:
  1. Oral polyethylene glycol from day 3
  2. Intravenous neostigmine from day 5

From Vincent JLet al: *Textbook of critical care*, ed 6, Philadelphia, 2011, Saunders.

REFERRAL

Ogilvie syndrome is best managed in a team approach involving both surgeons and gastroenterologists. Administration of neostigmine in proper candidates or decompressive colonoscopy should be pursued in patients with absence of peritoneal signs. If there is evidence of perforation, surgical management is indicated.

PEARLS & CONSIDERATIONS

COMMENTS

- Maximal supportive care should be initiated for up to 48 hr barring any significant abdominal pain or massive distention >12 cm on imaging.
- Administration of neostigmine is suggested in appropriate candidates.
- Colonic decompression should be attempted with or without decompression tube placement in patients who fail neostigmine or those who have contraindications to its use.
- Minimally invasive fluoroscopic, endoscopic, or surgical approaches are rarely needed.
- Surgery is reserved for patients who show signs of perforation.
- Oral laxatives should be discontinued with diagnosis but should be restarted once decompression is achieved.

PREVENTION

Box E2 describes some prevention strategies for Ogilvie syndrome in the critically ill.

AUTHOR: **Jason D. Ferreira, MD**

BASIC INFORMATION

Acute coronary syndrome (ACS) represents a spectrum of clinical disorders that includes unstable angina (UA), non–ST-elevation myocardial infarction (NSTEMI), and ST-elevation myocardial infarction (STEMI). Although the severity of disease will vary between the three subsets of ACS, they share a common clinical presentation and pathophysiology. This syndrome is typically caused by atherosclerotic coronary artery disease (CAD) and abrupt reduction in coronary blood flow. In this spectrum, UA and NSTEMI are represented electrocardiographically by the absence of ST-segment elevation in the appropriate clinical setting (i.e., chest discomfort). NSTEMI is additionally characterized by positive cardiac biomarkers because ischemia is severe enough to cause myocardial damage. STEMI is characterized by ST-segment elevation or presumed new left bundle branch block on electrocardiogram (ECG) in the appropriate clinical setting. ACS should be thought of as a continuous spectrum as UA will often progress to a myocardial infarction if left untreated (Table 1). Because of this continuum, the 2014 American College of Cardiology/American Heart Association (ACC/AHA) guidelines have grouped UA and NSTEMI into a single category called non–ST-elevation ACS (NSTE-ACS).

SYNONYMS

ACS
Unstable angina
NSTEMI
STEMI
Acute myocardial infarction

ICD-10CM CODES	
I20.0	Unstable angina
I21.0-I21.3	ST elevation (STEMI)
I21.4	Non-ST elevation (NSTEMI) myocardial infarction
I24.9	Acute ischemic heart disease, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: In the U.S., cardiovascular disease accounts for approximately 841,000 deaths each yr. The estimated annual incidence of heart attack in the U.S. is 720,000 new attacks and 335,000 recurrent attacks. Approximately 70% of myocardial infarctions are listed as NSTEMI, with the remainder being listed as STEMI. Patients with NSTE-ACS have more cardiac and noncardiac comorbidities than patients with STEMI. The underlying etiology, atherosclerotic CAD, is the number one cause of mortality.

PREDOMINANT SEX AND AGE: In evaluating chest pain, male gender and older age are important clinical factors that can identify ACS as a potential cause. The average age of first myocardial infarction is 65.6 yr old for men and 72.0 yr old for women. In a 2005-2011 study sponsored by National Heart, Lung, and Blood Institute, the average age-adjusted first MI or fatal coronary heart disease rates per 1000 population in patients age 35 to 84 yr of age were 3.7 for white men, 5.9 for black men, 2.1 for white women, and 4.0 for black women. As noted in this study, heart disease affects African Americans disproportionately. Heart disease is also the leading cause of death in women, surpassing all forms of cancer.

RISK FACTORS: Hypertension, diabetes mellitus, dyslipidemia, tobacco use, and family history of premature CAD (CAD in a male first-degree relative younger than 55 yr or a female younger than 65 yr) are all associated risk factors for CAD. There are also female-specific risk factors for CAD, including disorders of pregnancy and early onset of menopause. Refer to the topic "Angina Pectoris" for an extensive list of risk factors. Presence of these risk factors causes damage to the vascular endothelium and progression of atherosclerotic coronary artery plaques.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms often, but not always, include chest discomfort described as a pressure that may radiate to the shoulders, neck, jaw, or back. Typical angina is substernal in location, brought on by emotional or physical stress, and relieved with rest and/or nitroglycerin. The pain and discomfort associated with an ACS event is often diffuse rather than localized. It is often associated with diaphoresis.
- Women, diabetics, the elderly (>75 yr old), and postoperative patients often have an atypical presentation for ACS.
- Unstable angina has three typical presentations:
  1. Rest angina: Angina occurring at rest and prolonged usually for longer than 20 minutes.
  2. New-onset angina: New-onset angina of at least Canadian Cardiovascular Society (CCS) class III symptoms (Table 2).
  3. Increasing angina: Previously diagnosed angina that has become distinctly more frequent, longer in duration, or lower in threshold (i.e., increased by ≥1 CCS class to at least CCS class III severity).
- "Anginal equivalents" may include dyspnea, nausea, vomiting, and fatigue.
- ECG for NSTE-ACS may reveal transient ST-segment elevation, ST-segment depression, and/or new T-wave inversion. ECG for definition of STEMI will reveal at least 1-mm ST-segment elevation in two contiguous leads or new left bundle branch block in the appropriate clinical presentation.
- Physical examination findings alone are insufficient for the diagnosis of ACS. The physical examination may provide clues as to alternative diagnoses, such as aortic dissection (differences in pulse and blood pressure between the arms, murmur of aortic regurgitation), pericarditis (friction rub), cardiac tamponade (pulsus paradoxus), and pneumothorax (differential breath sounds.) In ACS it is important to assess the patient's hemodynamic stability, as signs of heart failure may be present. These signs include elevated jugular venous pressure (JVP), presence of an S3 gallop, and peripheral edema. The degree of heart failure with MI can be represented by the Killip classification, with the greater the Killip classification, the greater the mortality noted:
  1. Killip Class 1 is no heart failure.
  2. Killip Class 2 includes individuals with rales, elevated JVP, and S3 on examination.
  3. Killip Class 3 includes individuals with frank pulmonary edema.
  4. Killip Class 4 describes individuals in cardiogenic shock or hypotension with evidence of vasoconstriction noted.

ETIOLOGY

Atherosclerotic CAD is the underlying etiology. The hallmark of ACS is the vulnerable atherosclerotic plaque, which typically has a thin fibrous cap and a large lipid core. This vulnerable plaque ultimately ruptures, which leads to platelet activation and aggregation, leading to thrombus formation. STEMI typically results from complete thrombotic occlusion of a coronary artery, whereas NSTE-ACS often has partial occlusion. Angiographically, it is often the intermediate coronary artery lesions (30% to 50% diameter vessel stenosis) that lead to subtotal or total vessel occlusion in two thirds of STEMI cases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Chest pain mimicking ACS may be the result of various underlying disorders, some of which are also accompanied by ECG changes and/or cardiac biomarker release. Examples include acute pulmonary embolism, acute aortic dissection, pericarditis, myocarditis, costochondritis, pneumonia, tension pneumothorax, perforating ulcer, or Boerhaave syndrome. Refer to topics "Angina Pectoris," "Coronary Artery Syndrome," and "Myocardial Infarction" for extensive differential diagnoses of chest pain.

TABLE 1 Acute Coronary Syndromes

	Spectrum of Acute Coronary Syndrome		
	Unstable Angina	**NSTEMI**	**STEMI**
Chest discomfort	1	1	1
Cardiac biomarkers	2	1	1
ECG changes	TWI and/or ST depression	TWI and/or ST depression	ST elevation or presumed new left bundle branch block
Pathophysiology	Partial/transient thrombotic occlusion	Partial/transient thrombotic occlusion	Complete thrombotic occlusion

ECG, Electrocardiogram; *NSTEMI,* non–ST-segment elevation myocardial infarction; *STEMI,* ST-segment myocardial infarction; *TWI,* T-wave inversion.

TABLE 2 Grading of Angina Pectoris According to CCS Classification

Class	Description of Stage
I	"Ordinary physical activity does not cause ... angina," such as walking or climbing stairs. Angina occurs with strenuous, rapid, or prolonged exertion at work or recreation.
II	"Slight limitation of ordinary activity." Angina occurs on walking or climbing stairs rapidly; walking uphill; walking or stair climbing after meals; in cold, in wind, or under emotional stress; or only during the few hours after awakening. Angina occurs on walking 0.2 blocks on the level and climbing 0.1 flight of ordinary stairs at a normal pace and under normal conditions.
III	"Marked limitations of ordinary physical activity." Angina occurs on walking 1 to 2 blocks on the level and climbing 1 flight of stairs under normal conditions and at a normal pace.
IV	"Inability to carry on any physical activity without discomfort—anginal symptoms may be present at rest."

Adapted with permission from Campeau L. Grading of angina pectoris (letter), *Circulation* 54:522-523, 1976. © 1976, American Heart Association, Inc.

A report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines (Committee on the Management of Patients With Unstable Angina), *J Am Coll Cardiol* 36:970-1062, 2000.

WORKUP

Focused history and physical exam, 12-lead ECG, cardiac biomarkers, and chest radiograph (CXR). Initial biomarkers may not be positive early in the disease process. Often serial biomarkers are drawn every 6 to 8 hours for a total of three sets for the purposes of ruling out myocardial infarction (MI), or until peak to determine the severity of an established MI. Echocardiogram may reveal new regional wall motion abnormalities or newly depressed LV function or aneurysm formation. Fig. 1 summarizes the evaluation of patients for acute coronary syndrome.

LABORATORY TESTS:

- Biomarkers and, in particular, the rising and/or falling pattern play an important role in the early detection and diagnosis of acute coronary syndrome (ACS). While troponin is essential to the diagnosis of acute myocardial infarction, other markers have demonstrated utility in the setting of acute chest pain and ACS. CK-MB and myoglobin are two traditional markers that are frequently used in combination with troponin and will be elevated in the setting of NSTEMI or STEMI. See Fig. E2, *A* for timing of release of each biomarker. Troponin I is the most sensitive biomarker for cardiac myocyte damage and also predicts 42-day mortality in ACS. Troponin I is considered the gold standard biomarker for diagnosis of myocardial infarction (Fig. E2, *B*).
- Creatinine kinase-myocardial band (CK-MB) is the cardiac specific isoform of creatinine kinase (CK) and is found in high concentrations in the myocardium. After an acute myocardial injury, CK-MB levels peak within 4-6 hours. Its shorter half-life leads to normal values within 24 to 48 hours after an event. As such, CK-MB is especially useful when assessing a patient for possible reinfarction because troponin levels can often be elevated up to 2 wk after an acute myocardial infarction.
- Myocardial infarction cannot always be assumed to be the etiology of elevations in troponin levels. Cardiac conditions, including arrhythmias, hypotension/hypertension, heart failure, and myocarditis, are a few of the common conditions that can lead to elevated levels. Noncardiac conditions, including renal failure, sepsis, respiratory failure, and neurological diseases, may also lead to elevations in troponin.
- Meanwhile, other biomarkers also have significant prognostic value. Testing for B-type natriuretic peptide (BNP) has a class IIb recommendation in the 2014 NSTE-ACS guidelines for use as a prognostic tool in patients presenting with an MI. BNP >80 portends a high risk of death at initial presentation of a STEMI.

RISK MODELS & RISK SCORES

Risk models and scores such as TIMI (see "Risk Assessment" in "Myocardial Infarction" topic), PURSUIT, and GRACE based on clinical, ECG, and laboratory data at presentation help to discriminate patients at high risk versus low risk for short- and intermediate-term adverse outcomes (Fig. E2, *C*).

IMAGING STUDIES

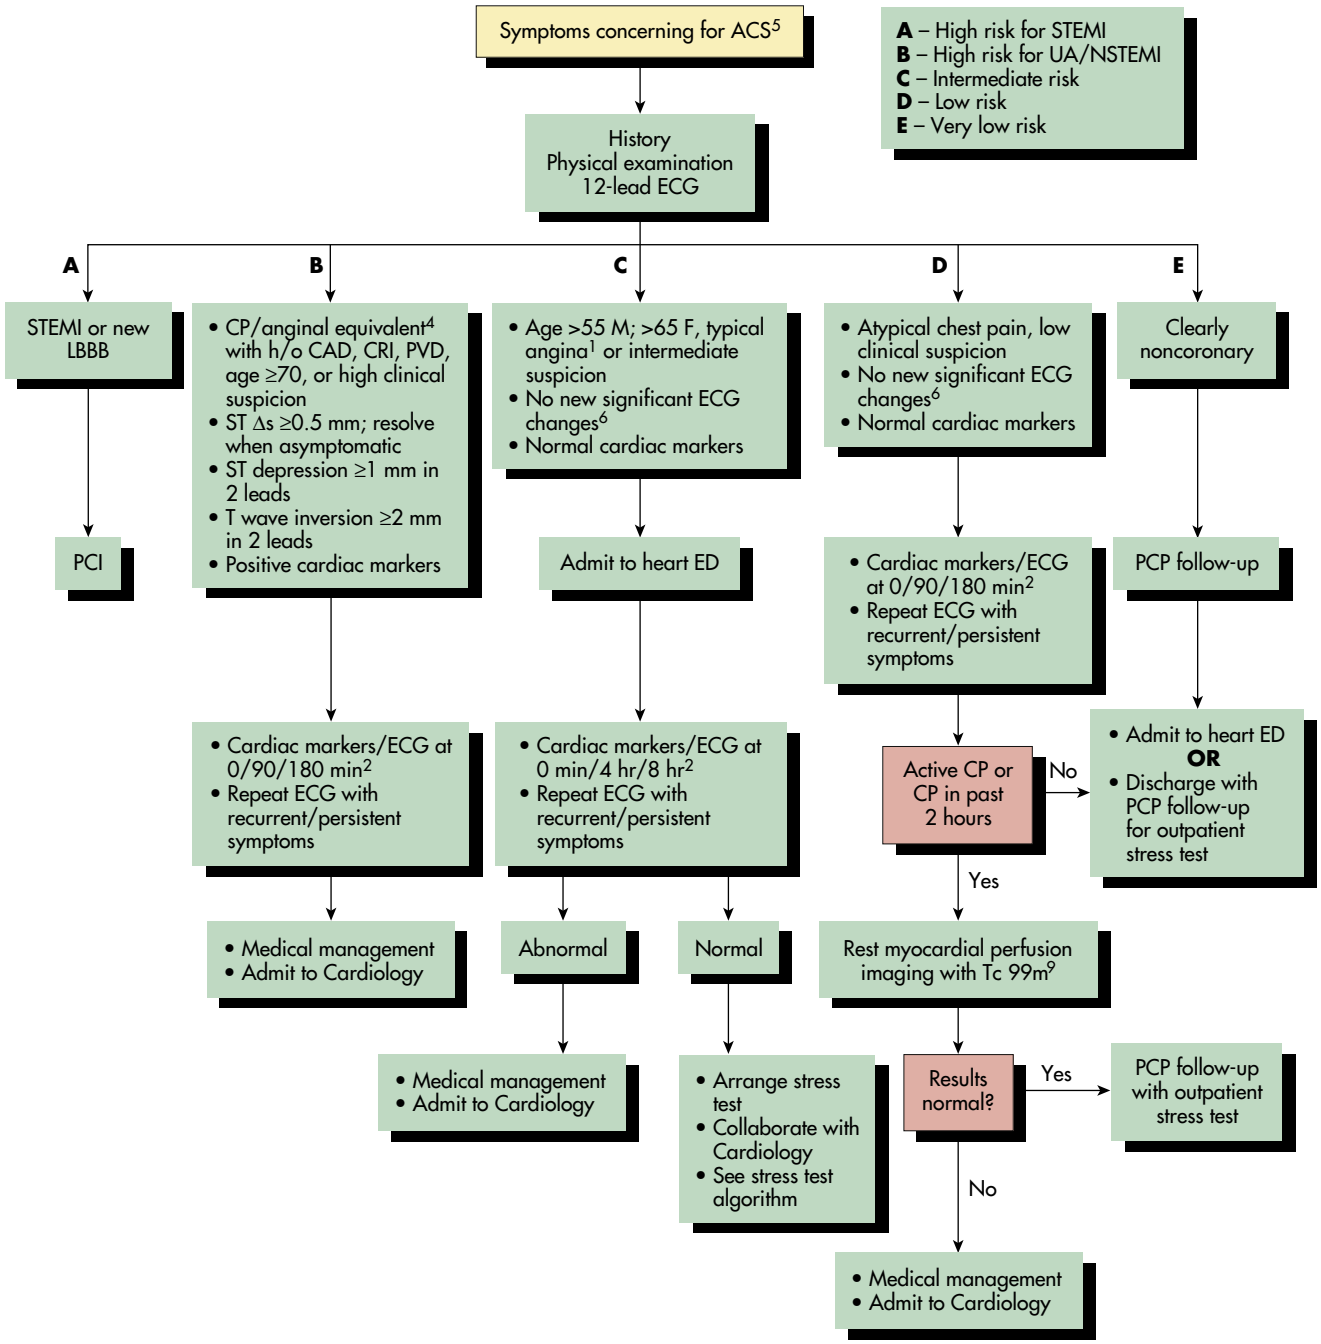
- A CXR to assist in evaluating for volume overload and possible widened mediastinum, which could be indicative of an aortic dissection. CXR can be useful in assessing for pneumonia, pneumothorax, and other pulmonary causes of chest pain.
- In patients for whom ECG and cardiac biomarkers are nondiagnostic but the suspicion for ACS is high given the history, an echocardiogram may be helpful to assess left ventricular (LV) function and regional wall motion abnormalities.
- Coronary CT angiography can be performed in patients with possible ACS, a normal 12-lead EKG result, negative troponin results, and no history of coronary artery disease (Class IIa).
- Cardiac stress testing (treadmill ECG, imaging stress studies using echocardiography or nuclear modalities) may further help to diagnose and risk stratify these patients. (See "Coronary Artery Syndrome" in Section I.)
- Coronary angiogram/cardiac catheterization will reveal coronary artery luminal irregularities/stenotic lesions. In patients with ACS who undergo coronary angiography, approximately 25% will have one vessel disease, 25% will have two vessel disease, 25% will have three vessel disease, 10% will have left main disease, and 15% will have coronary stenosis of <50% or normal coronaries.

Rx TREATMENT

The overall goal for patients with NSTE-ACS is to relieve myocardial ischemia and to prevent recurrent cardiovascular events. Antithrombotic therapy is needed to reduce thrombus burden, prevent further thrombosis, and improve coronary artery flow. Revascularization is needed to prevent further events and improve flow within the coronary artery lumen. For patients with STEMI, the goal is immediate reperfusion therapy, whether it is chemical (i.e., thrombolysis) or mechanical (i.e., percutaneous coronary intervention [PCI]), and time from onset of ischemia to revascularization is an important prognostic factor. STEMI patients presenting to a hospital with PCI capability should be treated with primary PCI within 90 minutes of first medical contact (Figs. 3 and 4). At non–PCI-capable hospitals where the first medical contact to balloon time is more than 120 minutes, thrombolytic therapy should be given if no contraindications are present; thrombolytics should not be administered 24 hours after initial diagnosis of STEMI. Absolute contraindications to thrombolytic therapy include the following: History of intracranial hemorrhage, known structural cerebral vascular lesion, known intracranial neoplasm, ischemic stroke within 3 mo, suspected aortic dissection, active bleeding, head trauma within 3 mo, or intracranial surgery within 2 mo. Relative contraindications include ischemic stroke more than 3 mo prior, dementia, major surgery within 3 wk, current oral anticoagulant therapy, and traumatic or prolonged CPR.

NONPHARMACOLOGIC THERAPY

- STEMI is a medical emergency and requires immediate reperfusion therapy; the best outcomes are seen with cardiac catheterization with primary PCI. Guidelines call for a goal door-to-balloon time of ≤90 minutes
- Patients with NSTE-ACS should be risk stratified in conjunction with the cardiology consult service. Risk scores such as the TIMI and GRACE scores can be used to decide between an early invasive strategy and an ischemia-guided strategy. Overall, an early invasive strategy is associated with better outcomes in patients with higher risk (i.e., TIMI score >3 or GRACE >140) and involves cardiac catheterization followed by revascularization with PCI or coronary artery bypass grafting (CABG) within 4 to 24 hours of presentation. An ischemia-guided strategy involves aggressive medical management and revascularization only if ischemia recurs or is documented on noninvasive testing. This should only be reserved for selected patients with low-risk scores (TIMI score 0 to 2). The early invasive strategy can be further stratified by timing:
  1. Immediate (within 2 hours): Patients with refractory or recurrent angina despite opti-



DEFINITIONS:

[1]Typical angina:
(1) Substernal chest pain or discomfort that is (2) provoked by exertion or emotional stress and (3) relieved by rest and/or nitroglycerin

[2]Cardiac marker timing: Based on symptom onset; in cases of uncertainty assume symptom onset at ED arrival

[3]ECG normal: No significant ST depression/T wave inversions, BBB, LVH with repolarization, conduction defect, digoxin effect

[4]Anginal equivalent:
- Any symptoms that the physician feels may represent ACS
- Exertional dyspnea—most common anginal equivalent symptom

[5]ACS:
- STE-ACS—1 mm ST elevation in 2 leads
- NSTE-ACS
  - NSTEMI—positive cardiac biomarkers
  - Unstable angina—ischemia with negative biomarkers

[6]New significant ECG changes:
- ST Δs ≥0.5 mm; resolve when asymptomatic
- ST depression ≥1 mm in 2 leads
- T wave inversion ≥2 mm in 2 leads

[7]Regadenoson is preferred agent for chemical nuclear stress test. Technetium Tc-99m tetrofosmin is the preferred tracer.

FIG. 1 Evaluation of patients for acute coronary syndrome *(ACS).* *CAD,* Coronary artery disease; *CP,* chest pain; *CRI,* chronic renal insufficiency; *ECG,* electrocardiogram; *ED,* emergency department; *h/o,* history of; *LBBB,* left bundle branch block; *NSTE,* non–ST-segment elevation; *NSTEMI,* non–ST-segment elevation myocardial infarction; *PCP,* primary care physician; *PVD,* peripheral vascular disease; *STE,* ST-segment elevation; *STEMI,* ST-segment elevation myocardial infarction; *UA,* unstable angina. (From Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.)

mal initial treatment, signs or symptoms of heart failure, new or worsening mitral regurgitation, hemodynamic instability, sustained ventricular tachycardia or ventricular fibrillation

2. Early (within 24 hours): No characteristics from the immediate category but new ST-segment depression, a GRACE risk score >140 or temporal change in troponin

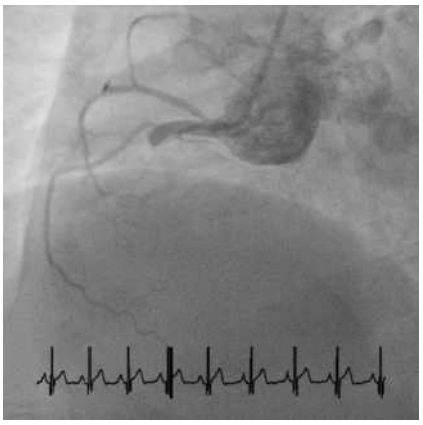


FIG. 3 Right coronary artery totally occluded proximally during ST-elevation myocardial infarction.

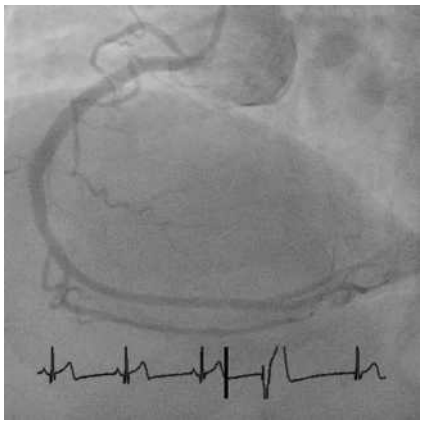

FIG. 4 Right coronary artery after successful percutaneous coronary artery stenting during ST-elevation myocardial infarction.

3. Delayed invasive (25 to 72 hours): None of the immediate or early characteristics but renal insufficiency, left ventricular ejection fraction of <40%, early post-infarct angina, history of PCI within the past 6 mo, prior coronary artery bypass graft, GRACE risk score of 109 to 140, or TIMI score of 2 or more

- Continuous ECG monitoring is recommended for all ACS patients. Supplemental oxygen should be administered to patients with arterial oxygen saturation of less than 90%, respiratory distress, or other high-risk features of hypoxemia. Finger pulse oximetry should be utilized to assess arterial oxygen saturation.

ACUTE GENERAL Rx

- Table 3 is a summary of recommendations for standard medical therapy in the early hospital care phase of management of patients with NSTE-ACS.
- Antithrombotic therapy (Table 4) is critical in treating the underlying pathophysiology

TABLE 3 Summary of Recommendations for Standard Medical Therapy in the Early Hospital Care Phase of Management of Patients with Non–ST-Elevation Acute Coronary Syndromes (NSTE-ACS)

Recommendations	COR	LOE
Oxygen		
Administer supplemental oxygen only with oxygen saturation <90%, respiratory distress, or other high-risk features for hypoxemia.	I	C
Nitrates		
Administer sublingual NTG every 5 min ×3 for continuing ischemic pain and then assess need for IV NTG.	I	C
Administer IV NTG for persistent ischemia, HF, or hypertension.	I	B
Nitrates are contraindicated with recent use of a phosphodiesterase inhibitor.	III: Harm	B
Analgesic Therapy		
IV morphine sulfate may be reasonable for continued ischemic chest pain despite maximally tolerated anti-ischemic medications.	IIb	B
NSAIDs (except aspirin) should not be initiated and should be discontinued during hospitalization for NSTE-ACS because of the increased risk of MACE associated with their use.	III: Harm	B
Beta-Adrenergic Blockers		
Initiate oral beta blockers within the first 24 hr in the absence of HF, low-output state, risk for cardiogenic shock, or other contraindications to beta blockade.	I	A
Use of sustained-release metoprolol succinate, carvedilol, or bisoprolol is recommended for beta-blocker therapy with concomitant NSTE-ACS, *stabilized* HF, and reduced systolic function.	I	C
Reevaluate to determine subsequent eligibility in patients with initial contraindications to beta blockers.	I	C
It is reasonable to continue beta-blocker therapy in patients with normal LV function with NSTE-ACS.	IIa	C
IV beta blockers are potentially harmful when risk factors for shock are present.	III: Harm	B
Calcium Channel Blockers (CCBs)		
Administer initial therapy with nondihydropyridine CCBs with recurrent ischemia and contraindications to beta blockers in the absence of LV dysfunction, increased risk for cardiogenic shock, PR interval >0.24 sec, or second- or third-degree atrioventricular block without a cardiac pacemaker.	I	B
Administer oral nondihydropyridine calcium antagonists with recurrent ischemia after use of beta blocker and nitrates in the absence of contraindications.	I	C
CCBs are recommended for ischemic symptoms when beta blockers are not successful, are contraindicated, or cause unacceptable side effects.*	I	C
Long-acting CCBs and nitrates are recommended for patients with coronary artery spasm.	I	C
Immediate-release nifedipine is contraindicated in the absence of a beta-blocker.	III: Harm	B
Cholesterol Management		
Initiate or continue high-intensity statin therapy in patients with no contraindications.	I	A
Obtain a fasting lipid profile, preferably within 24 hr.	IIa	C

*Short-acting dihydropyridine calcium channel antagonists should be avoided.

COR, Class of recommendation; *HF,* heart failure; *IV,* intravenous; *LOE,* level of evidence; *LV,* left ventricular; *MACE,* major adverse cardiovascular events; *N/A,* not available; *NSAIDs,* nonsteroidal anti-inflammatory drugs; *NTG,* nitroglycerin.

From Amsterdam EA et al: 2014 AHA/ACC guideline for the management of patients with non–ST-elevation acute coronary syndromes: A report of the American College of Cardiology/American Heart Association task force on practice guidelines. *J Am Coll Cardiol* 64:e139-228, 2014 in Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

of ACS. This consists of administering antiplatelet and anticoagulant agents (Table 5).

- Antiplatelet agents (Table 6) inhibit platelet activation and aggregation. Aspirin is a cyclooxygenase inhibitor that blocks platelet aggregation and should be administered to all ACS patients without contraindications.
- All patients with ACS should receive full-dose non–enteric-coated chewable aspirin of 162 to 325 mg to establish a high blood level for its antiplatelet effects. Thereafter, daily dose of 81mg should be continued indefinitely.
- Clopidogrel is a thienopyridine agent that inhibits platelet activation and aggregation. It should be administered in all ACS patients, with the timing dependent on the clinical scenario and management strategy. It requires a loading dose of 300 to 600 mg followed by 75 mg daily. It should be discontinued at least 5 days before CABG. If a patient is unable to take aspirin in the setting of hypersensitivity or major gastrointestinal intolerance, a loading dose of clopidogrel followed by daily maintenance should be started.
- Other antiplatelet agents that can be substituted instead of clopidogrel include prasugrel and ticagrelor. Ticagrelor has a half-life of 12 hours with a more rapid onset and more consistent onset of action. There was a reduction in death from vascular causes, MI, and stroke in patients with NSTE-ACS over clopidogrel. This benefit is limited to patients taking aspirin 75 to 100 mg per day. Prasugrel is not recommended in patients with NSTE-ACS. Multiple studies have demonstrated an increase in bleeding in patients taking Prasugrel, in particular those with a history of cerebrovascular events. Cangrelor is an IV ADP-P2Y12 receptor antagonist that may be used initially as a load in the emergency department before an invasive strategy, given its initial action and quick platelet recovery time. As a rule, all ACS patients should have two antiplatelet agents initiated and should be continued up to 12 mo regardless of ischemia-guided vs. invasive strategy.
- GP IIB/III a inhibitors (Table 7) may be considered as an intravenous antiplatelet therapy in addition to aspirin for medium- or high-risk patients with NSTE-ACS in whom an invasive strategy is planned (Class IIb). Eptifibatide and tirofiban are preferred agents over abciximab for NSTE-ACS patients; however, for STEMI patients undergoing primary PCI, IV abciximab has the same Class IIa indication as tirofiban and eptifibatide.
- Anticoagulant agents should be administered to all ACS patients, irrespective of initial treatment strategy. Options include either unfractionated heparin (UFH), or low-molecular-weight heparin (enoxaparin), or factor Xa inhibitors such as fondaparinux, or direct thrombin inhibitors such as bivalirudin (Table 8).
- For STEMI, fondaparinux can be used for anticoagulation. It has been shown to decrease bleeding complications as compared with either UFH or LMWH. However, it should not

TABLE 5 2014 Guideline Recommendations for Antithrombotic Agents in Patients with Non–ST-Elevation Acute Coronary Syndromes

Antiplatelet Therapy

Non–enteric-coated, chewable aspirin (162 to 325 mg) should be given to all patients without contraindications on presentation, and a maintenance dose of aspirin (81 to 325 mg/day) continued indefinitely.

In patients who are unable to take aspirin because of hypersensitivity or major gastrointestinal intolerance, a loading dose of clopidogrel (300 or 600 mg) followed by a daily maintenance dose of 75 mg should be substituted.

Either clopidogrel or ticagrelor can be used initially with either an early invasive or ischemic guided strategy (COR I, LOE: B).

Ticagrelor may be preferred over clopidogrel as the initial treatment (COR IIa, LOE: B).

In patients treated with ticagrelor, the preferred aspirin maintenance dose is 81 mg/day.

Use prasugrel only in patients receiving coronary stents (COR I, LOE: B).

The use of glycoprotein IIb/IIIa receptor inhibitors is reserved mainly to the time of PCI in high-risk patients who were not adequately pretreated with $P2Y_{12}$ inhibitors (COR I, LOE: A) or in those patients who were adequately pretreated with $P2Y_{12}$ inhibitors but have a high-risk profile (COR IIa, LOE: B).

Clopidogrel and ticagrelor should be discontinued at least 5 days (COR I, LOE: B) and prasugrel at least 7 days (COR I, LOE: C) before major surgery.

Anticoagulant Therapy

Enoxaparin is recommended at presentation (COR I, LOE: A); other options include unfractionated heparin (UFH) (COR I, B) and fondaparinux (COR I, LOE: B). If an early invasive strategy is planned, bivalirudin (COR I, LOE: B) is also an option.

If fondaparinux is used initially, add UFH or bivalirudin just before or during PCI to prevent catheter-related thrombosis (COR I, LOE: B).

Bivalirudin is preferred over UFH plus GP IIb/IIIa inhibitor in patients undergoing PCI who are at high risk of bleeding (COR IIa, LOE: B).

It is reasonable to use enoxaparin during PCI if it was used as the initial anticoagulant (COR IIb, LOE: B).

COR, Class of recommendation; *LOE,* level of evidence; *PCI,* percutaneous coronary intervention.

Antiplatelet and anticoagulation treatment in patients with non–ST-segment elevation acute coronary syndrome: comparison of the updated North American and European guidelines. *Cardiol Rev* 24:170-6, 2016; and Amsterdam EA et al: 2014 AHA/ACC guideline for the management of patients with non–ST-elevation acute coronary syndromes: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. *J Am Coll Cardiol* 64: e139-228, 2014, in Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

TABLE 6 Pharmacologic Characteristics of Oral Antiplatelet Drugs Commonly Used in the Management of Acute Coronary Syndromes

		ADP Receptor Antagonists		
Characteristic	**Aspirin**	**Clopidogrel**	**Prasugrel**	**Ticagrelor**
Class	COX inhibitor	Thienopyridine (second generation)	Thienopyridine (third generation)	Cyclopentyl triazolopyrimidine
Target	COX-1	P2Y12	P2Y12	P2Y12
Dose	162–325-mg loading dose; 75-325mg/day maintenance dose	300–600-mg loading dose; 75mg/day maintenance dose	60-mg loading dose; 10mg/day maintenance dose	180-mg loading dose; 90 mg bid maintenance dose
Prodrug	No	Yes	Yes	No
Time to effect[a]	<1 hour	4-6 hours[b]	<1 hour	<1 hour
Drug half-life	20 min	Minutes	Minutes	12 hours
Reversible	No	No	No	Yes

ADP, Adenosine diphosphate; bid, twice daily; *COX,* cyclooxygenase.

[a]After loading dose

[b]Increased antithrombotic benefit was seen after the first hour in patients enrolled in the COMMIT trial who did not receive a loading dose, but maximum effect is not seen until after 4-6 hours.

From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

be used as the sole anticoagulant in PCI because of the risk of catheter thrombosis.

- Bivalirudin is a reversible direct thrombin inhibitor and may be considered as an alternative to UFH and GP IIb/IIIa inhibitors in patients with STEMI (HORIZONS AMI trial) who are undergoing primary PCI. When bivalirudin was compared to UFH plus a glycoprotein IIb/IIIa inhibitor in patients with STEMI and PCI, less bleeding and a short- and long-term reduction in cardiac events and overall mortality was observed. With bivalirudin, there is no risk of heparin-induced thrombocytopenia, less bleeding is observed, and the anticoagulant effect can be monitored during intervention by the activated clotting time. Similar results were reported in the use of bivalirudin alone in patients with UA/NSTEMI in the ACUITY trial when compared to enoxaparin/UFH with GP IIb/IIIa arms.
- Beta-blocker therapy reduces ischemia by decreasing myocardial oxygen demand and has a proven long-term mortality benefit. Oral therapy should be initiated within 24 hours of onset of ACS unless signs or symptoms of heart failure and shock are present or arrhythmias preclude its use. Oral administration, titrated to a heart rate of 50-60 beats/min, is preferred. Intravenous beta-blockers can be administered to STEMI patients who are hypertensive or have ongoing ischemia; they should be avoided if the patients have any of the following:
  1. Signs of heart failure.
  2. Evidence of a low output state.
  3. Increased risk for cardiogenic shock.
  4. Other relative contraindications to beta-blockade (PR interval >0.24 second, second- or third-degree heart block, active asthma, or reactive airway disease).
- Nitroglycerin is a vasodilator that should be administered to relieve chest discomfort in all ACS patients. It can be administered sublingually at first, up to 3 doses, followed by intravenous administration if symptoms persist. In the setting of an inferior STEMI, it is necessary to rule out a right ventricular (RV) infarct with a right-sided ECG before the administration of nitroglycerin. This is because RV infarcts are preload dependent and nitroglycerin decreases preload through venodilation, which leads to hypotension in this setting. This can be corrected by discontinuing nitroglycerin and starting bolus intravenous fluids. Nitrates should not be administered in patients who recently received a phosphodiesterase inhibitor. Nitroglycerin provides no mortality benefit in ACS patients.
- Oxygen should be administered to patients with shortness of breath, signs of acute heart failure, cardiogenic shock, or an arterial oxyhemoglobin saturation of less than 90%. The 2014 ACC/AHA guidelines report no demonstrated benefit for routine use of supplemental oxygen in normoxic patients

TABLE 7 Pharmacologic Characteristics of Intravenous Antiplatelet Drugs Used in the Management of Acute Coronary Syndrome

	GP IIb/IIIa inhibitors			ADP Receptor Antagonists

ACS, Acute coronary syndromes; *aPTT,* activated partial thromboplastin time; *CrCl,* creatinine clearance; *HIT,* heparin-induced thrombocytopenia; *IV,* intravenous; *SC,* subcutaneous.
[a]The first dose of enoxaparin was given by the intravenous route in the TIMI-11B (Thrombolysis In Myocardial Infarction 11B) and EXTRACT-TIMI 25 (Enoxaparin and Thrombolysis Reperfusion for Acute Myocardial Infarction Treatment, Thrombolysis in Myocardial Infarction 25) studies. The first dose of fondaparinux was given by the intravenous route in the OASIS-6 (Optimal Antiplatelet Strategy for Interventions 6) trial.
[b]Acute coronary syndrome patients with creatinine up to 265 μmol/L were eligible for inclusion in the OASIS-5 and -6 trials (equivalent to an estimated creatinine clearance of 15-20 ml/min in a 70-kg patient who is 70 yr of age).
[c]Fondaparinux is contraindicated in patients with venous thromboembolism who have severe renal impairment.
[d]Monitoring and dose adjustment required in patients with creatinine clearance below 30 ml/min.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

with NSTE-ACS; rather, emerging data suggest that routine use of oxygen can lead to adverse effects such as increased coronary vascular resistance, reduced coronary blood flow, and increased mortality rate.

- Morphine can be used intravenously in patients with NSTE-ACS if there is continued ischemic chest pain despite treatment with maximally tolerated anti-ischemic medications (Class IIb).
- Calcium channel blockers (nondihydropyridine) may be used in patients with persisting or recurrent symptoms, despite treatment with beta-blockers and nitroglycerin. They work by having negative inotropic and chronotropic effects and causing coronary vasodilation. They are especially useful when beta-blockers are contraindicated and in patients with coronary artery spasm. Calcium channel blockers should not be used in cases of severe LV dysfunction, pulmonary edema, increased risk for cardiogenic shock or advanced heart blocks.
- Patients routinely taking nonsteroidal antiinflammatory drugs (NSAIDs) (except for aspirin), both nonselective as well as COX-2 selective agents, before ACS should discontinue those agents at the time of presentation because of the increased risks of mortality, reinfarction, hypertension, heart failure, and myocardial rupture associated with their use.
- Angiotensin-converting enzyme (ACE) inhibitors may be added and should be used within 24 hours of onset of ACS in all patients with depressed LV function (ejection fraction [EF] <40%) and those with a history of hypertension, diabetes mellitus, or stable chronic kidney disease. Angiotensin receptor blockers (ARBs) should be used in patients who are ACE inhibitor intolerant.
- Table 9 summarizes indications and cautions for adjunctive medical therapies for patients with ST-elevation myocardial infarction.
- Refer to topic "Cocaine Overdose" for treatment of cocaine-related ACS.

CHRONIC Rx

- Post-ACS medical therapy involves aspirin, statin, beta-blocker, and a second anti-platelet agent such as clopidogrel, ticagrelor, or prasugrel.
- In patients already on an oral anticoagulant for another diagnosis such as atrial fibrillation, the duration of triple therapy should be minimized. Strategies aimed at minimizing the risk of bleeding in patients treated with triple therapy (dual antiplatelet therapy and an oral anticoagulant) are summarized in Table 10. The WOEST trial showed that using clopidogrel along with an oral anticoagulant but without aspirin resulted in a significant reduction in bleeding complications with those patients on a triple therapy of oral anticoagulant, aspirin, and clopidogrel. It is a class IIB recommendation in those patients with atrial fibrillation and a CHADS-VASC score of 2 or greater after coronary revascularization to consider using clopidogrel concurrently

with oral anticoagulant (Table 11) but without aspirin. Similarly, the AUGUSTUS trial in 2019 demonstrated that triple therapy (ASA, P2Y12 inhibitor, DOAC or warfarin) was associated with substantial increases in bleeding without improved thrombotic protection compared with P2Y12 inhibitor and oral anticoagulation alone.

- Lipid lowering with statins has been evaluated in trials such as the MIRACL study, in which high-dose atorvastatin 80 mg reduced death, MI, and cardiac events at 16 wk when administered early, within 24 to 96 hours after an ACS. The A-Z trial and PROVE IT-TIMI 22 trials demonstrated benefit of early high-intensity statin therapy with LDL targets <70 mg/dl in ACS.
- ACE inhibitors may be added to treat hypertension and should be used in all patients with depressed LV function (EF <40%) or pulmonary vascular congestion. ARBs should be used in patients who are ACE inhibitor intolerant.
- An aldosterone blocker should be used in post-MI patients without significant renal dysfunction (creatinine >2.5 mg/dl in men or creatinine >2.0 mg/dl in women) or hyperkalemia (K >5.0 mEq/L) who have an ejection fraction of less than 40% and are already on therapeutic doses of an ACE inhibitor and a beta-blocker.
- Cardiac rehabilitation and a monitored exercise program should be recommended at the time of discharge.
- Aggressive risk factor management, including smoking cessation, weight loss, diet and exercise, diabetes control, and so on, for secondary prevention of future events is crucial.

REFERRAL

- All ACS patients should be cared for in conjunction with the cardiology consult service.
- When appropriate, referral to a cardiac surgeon may be necessary for CABG and heart team approach.
- At the time of discharge, patients should be referred for cardiac rehabilitation.

PEARLS & CONSIDERATIONS

COMMENTS

- ACS is common and a leading cause of mortality in the U.S.
- The diagnosis hinges on the basics—history and physical, ECG, biomarkers, and CXR.
- Remember the potentially fatal non-ACS causes of chest discomfort, which include acute pulmonary embolism and acute ascending aortic dissection.
- STEMI patients presenting to a hospital with PCI capability should be treated with primary PCI within 90 minutes of first medical contact.
- STEMI patients presenting to a hospital without PCI capability and who cannot be transferred to a PCI center and undergo PCI within 120 minutes of first medical contact should be treated with fibrinolytic therapy within 30 minutes of hospital presentation unless fibrinolytic therapy is contraindicated.
- Refer to topics "Angina Pectoris" and "Myocardial Infarction" for additional discussion of this subject matter.

PREVENTION

Primary prevention of ACS is based on recognizing the major risk factors for CAD:

- Patients should be counseled to end all tobacco use by developing a plan for quitting that may include pharmacotherapy or a referral to a smoking cessation program.
- Patients with blood pressure ≥130/80 mm Hg should be treated, as tolerated, with blood pressure medication, treating initially with β-blockers and/or ACE inhibitors, with addition of other drugs as needed to achieve goal blood pressure.
- All patients should be counseled regarding the need for lifestyle modification: Weight control; increased physical activity; alcohol moderation; sodium reduction; and emphasis on increased consumption of fresh fruits, vegetables, and low-fat dairy products.
- It may also be reasonable to add omega 3 fatty acids from fish or fish oil capsules for cardiovascular disease reduction.
- Patients should be encouraged to perform 30 to 60 minutes of moderate intensity aerobic activity for a minimum of 5 days a week.
- Body mass index and waist circumference should be assessed at every visit and patients should be encouraged to maintain/achieve a body mass index between 18.5 and 24.9 kg/m^2.
- Patients with diabetes mellitus should maintain strict control of their glucose and A1C, under the care of their primary care physician or endocrinologist. Metformin is first-line pharmacotherapy. Target HbA1c of ≤7% may be considered.
- For patients with recent myocardial infarction or coronary artery bypass surgery, it is beneficial to screen for depression.

TABLE 9 Indications and Cautions for Adjunctive Medical Therapies for Patients with ST-Elevation Myocardial Infarction

Therapy	Indications	Cautions
Beta-adrenergic receptor–blocking agents	Oral: All patients without contraindication IV: Patients with refractory hypertension or ongoing ischemia without contraindication	Signs of congestive heart failure Low-output state Increased risk for cardiogenic shock Prolonged first-degree or high-grade atrioventricular block Reactive airways disease
Angiotensin-converting enzyme (ACE) inhibitors	Anterior myocardial infarction and LVEF ≤0.40 or congestive heart failure All patients without contraindication	Hypotension Renal failure Hyperkalemia
Angiotensin receptor–blocking agents (ARBs)	Intolerant of ACE inhibitors	Hypotension Renal failure Hyperkalemia
Statins	All patients without contraindications	With drugs metabolized via CYP3A4, fibrates Monitor for myopathy, hepatotoxicity Adjust dose for lipid targets
Nitroglycerin	Ongoing chest pain Hypertension and congestive heart failure	Suspected right ventricular infarction SBP <90 (or 30 mm Hg below baseline) Recent use of a type 5 PDE inhibitor
Oxygen	Clinically significant hypoxemia (Spo_2 <90) Congestive heart failure Dyspnea	Chronic obstructive pulmonary disease and CO_2 retention
Morphine	Pain Anxiety Pulmonary edema	Lethargic or moribund patient Hypotension Bradycardia Known hypersensitivity

IV, Intravenous; *LVEF,* left ventricular ejection fraction; *PDE,* phosphodiesterase; *SBP,* systolic blood pressure.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

- All eligible patients should be referred to a comprehensive cardiac rehabilitation program.
- Patients with depressed LV function (ejection fraction <35%) at least 40 days after an acute MI benefit from an implantable cardioverter defibrillator (ICD) for the prevention of sudden cardiac death.

TABLE 10 Strategies Aimed at Minimizing the Risk of Bleeding in Patients Treated with Triple Therapy (Dual Antiplatelet Therapy and an Oral Anticoagulant)

Proposed Approach	Rationale
Aspirin maintenance dose ≤100 mg/day	Higher aspirin maintenance doses increase bleeding, and there is no evidence that they improve efficacy.
PPI with a preference for agents that interfere less with CYP 2C19 (e.g., pantoprazole)	Much of the excess bleeding is from the GI tract. The use of acid-suppressive agents that interfere less with CYP 2C19 minimizes the potential for a negative interaction with clopidogrel.
Preference for a non–vitamin K antagonist oral anticoagulant	Dabigatran 110 mg twice daily and apixaban 2.5 or 5.0 mg twice daily are associated with lower rates of bleeding than warfarin.
For warfarin, use a target INR of 2–2.5	Some evidence that a restricted target INR range reduces the risk of bleeding.
Manage warfarin in a specialized anticoagulation clinic	Compared with usual care, specialist clinics achieve a higher TTR of the INR.
Minimize duration of triple therapy	The risk of bleeding is highest during the first 30 days but remains elevated with long-term treatment.
Avoid NSAIDs	NSAIDs are a common cause of upper GI bleeding.
Avoid prasugrel and ticagrelor	Prasugrel and ticagrelor cannot be recommended because they are more potent than clopidogrel and cause more bleeding.

BASIC INFORMATION

DEFINITION

Acute glomerulonephritis (GN) is inflammation of the glomeruli, usually caused by deposition of immunoreactants. Clinically, patients present with blood and protein in the urine and high blood pressure. If untreated, chronic glomerular inflammation leads to progressive chronic kidney disease.

SYNONYMS

Acute nephritic syndrome
Glomerulonephritis, acute GN

ICD-10CM CODES

N00.0	Acute nephritic syndrome with minor glomerular abnormality
N00.1	Acute nephritic syndrome with focal and segmental glomerular lesions
N00.2	Acute nephritic syndrome with diffuse membranous glomerulonephritis
N00.3	Acute nephritic syndrome with diffuse mesangial proliferative glomerulonephritis
N00.4	Acute nephritic syndrome with diffuse endocapillary proliferative glomerulonephritis
N00.5	Acute nephritic syndrome with diffuse mesangiocapillary glomerulonephritis
N00.6	Acute nephritic syndrome with dense deposit disease
N00.7	Acute nephritic syndrome with diffuse crescentic glomerulonephritis
N00.8	Acute nephritic syndrome with other morphologic changes
N00.9	Acute nephritic syndrome with unspecified morphologic changes

EPIDEMIOLOGY & DEMOGRAPHICS

- Incidence of primary glomerulonephritis varies between 0.2/100,000 per yr and 2.5/100,000 per yr.
- Immunoglobulin A (IgA) nephropathy is the most common form of glomerulonephritis worldwide.
- Glomerulonephritis accounts for 23% of end-stage kidney disease cases worldwide.
- Glomerulonephritis affects adults and children.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute onset of hypertension.
- Dark, "tea-colored" urine.
- Edema (peripheral, periorbital, or pulmonary).
- Fatigue.
- Concurrent pulmonary hemorrhage and rapidly progressive decline in kidney function may indicate antineutrophil cytoplasmic antibody (ANCA) vasculitis or anti-glomerular basement membrane (anti-GBM) disease.
- Joint pains, oral ulcers, and malar rash are frequently seen with systemic lupus erythematosus (SLE).
- Palpable purpura may be seen in patients with systemic vasculitides such as Henoch-Schönlein purpura, ANCA-associated vasculitis, SLE, or cryoglobulinemia.
- A recent history of endocarditis, cellulitis, or pharyngitis preceding urinary abnormalities may indicate infection-related glomerulonephritis.
- Hepatitis C virus infection may cause membranoproliferative glomerulonephritis (MPGN) with or without cryoglobulinemia.
- Concurrent upper respiratory tract infection (synpharyngitic infection) and gross hematuria may indicate IgA nephropathy.
- Table 1 summarizes the clinical and laboratory features of the different causes of rapidly progressive glomerulonephritis.

ETIOLOGY

Acute glomerulonephritis (GN) may occur as a renal-limited disease or part of a systemic disorder. A description of target antigens is included in Table 2.

In the past decade, the knowledge of the pathogeneses of several acute GNs has greatly expanded. IgA nephropathy is thought to be caused by a multi-hit process that involves under-galactosylated IgA1, development of anti-glycan antibodies, and deposition of immune complexes in the kidney. Post-streptococcal GN is now part of infection-related glomerulonephritis, a broader category that includes IgA-dominant staphylococcus-associated GN. ANCA-associated vasculitis is associated with antibodies to myeloperoxidase and proteinase 3, although not all studies have supported direct disease causation. C3 glomerulopathy, composed of C3 glomerulonephritis and dense deposit disease, is caused by dysregulation of the alternative complement pathway. The alternative complement pathway is now implicated in several different GNs, including IgA nephropathy and ANCA-associated vasculitis, which may have treatment implications in the future.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS FOR HEMATURIA AND/OR PROTEINURIA, IN ADDITION TO ACUTE GLOMERULONEPHRITIS

- Urinary tract infection
- Nephrolithiasis
- Urothelial malignancy
- Polycystic kidney disease
- Acute interstitial nephritis
- Acute tubular necrosis
- Nephrotic syndrome
- Hereditary nephritis (Alport syndrome and thin basement membrane nephropathy)
- Diabetic nephropathy

WORKUP

Initial evaluation of suspected glomerulonephritis consists of laboratory testing.

LABORATORY TESTS

- Urinalysis, with albuminuria (majority of proteinuria in glomerulonephritis is albuminuria) and hematuria (dysmorphic erythrocytes and red cell casts).
- Blood urea nitrogen and serum creatinine to estimate glomerular filtration rate (GFR).
- 24-hour urine collection for total protein excretion (includes albumin plus tubular proteins) and creatinine clearance to document degree of renal dysfunction. Random urine (spot) specimen for evaluation of the protein-to-creatinine ratio instead of a 24-hour collection is also acceptable. Proteinuria in acute glomerulonephritis typically ranges from 500 mg/day to 3 gram/day, but nephrotic-range proteinuria (>3.5 g/day) may be present.
- Streptococcal tests (Streptozyme) and anti-streptolysin O (ASO) quantitative titer (highest in 3 to 5 weeks). The ASO titer is not related to severity of kidney disease, duration, or prognosis.
- Additional serologic testing, including anti-nuclear antibody (ANA), antibody directed against double-stranded DNA (anti-dsDNA), C3, C4, hepatitis B and C viral serologies, HIV, ANCA (myeloperoxidase and proteinase-3 antigens), anti-glomerular basement membrane (GBM) antibodies, cryoglobulins, rheumatoid factor, serum and urine protein electrophoresis with immunofixation, and serum free light chain analysis.
- Hematocrit and platelet count are decreased in thrombotic microangiopathies.
- Blood cultures are indicated in all febrile patients.

IMAGING STUDIES

- Chest x-ray: If opacities present, consider diffuse alveolar hemorrhage as seen in ANCA-associated vasculitis and anti-GBM disease (Goodpasture syndrome).
- Renal ultrasound to exclude structural causes of hematuria and proteinuria. A kidney size of <9 cm in sagittal length may indicate extensive scarring and a low likelihood of reversibility.
- Echocardiogram in patients with new cardiac murmurs or positive blood cultures to rule-out endocarditis and pericardial effusion.
- Kidney biopsy with light, electron, and immunofluorescence microscopy to establish diagnosis.
- Biopsy of other affected organs if systemic vasculitis is suspected.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Low-salt diet if edema or hypertension is present.
- Avoidance of high-potassium foods if patient is hyperkalemic.

ACUTE GENERAL Rx

- Diuretics in patients with significant edema or hypertension.
- Correction of electrolyte abnormalities (hypocalcemia, hyperkalemia) and acidosis.
- High-dose steroids (1 mg/kg/day) for rapidly progressive glomerulonephritis.
- Additional immunosuppressive treatment with alkylating agents, calcineurin inhibitors, antimetabolites, or biologic agents may be required depending on the underlying disease.

TABLE 1 Clinical and Laboratory Features in the Different Causes of Rapidly Progressive Glomerulonephritis

Disease	Typical Clinical Features	Serologic Findings	Complement Levels	Immune Deposits in Glomerulus on Renal Biopsy
Vasculitis				Few/pauci-immune
Granulomatosis with polyangiitis (Wegener granulomatosis)	Prodrome of nasal stuffiness, blocked ears, arthralgia; then onset of hemoptysis, purpura, peripheral neuropathy	C-ANCA	Normal or increased	
Microscopic polyangiitis	Similar to granulomatosis with polyangiitis (Wegener granulomatosis) or affecting the kidneys only (renal-limited) or overlap with polyarteritis nodosa	P-ANCA	Normal or increased	
Anti-GBM disease	Macroscopic hematuria and hemoptysis	Anti-GBM antibodies	Normal or increased	Linear staining for IgG and C3
SLE (diffuse proliferative, WHO class IV)	Previous history of SLE, marked hematuria and proteinuria, hypertension "telescoping" urinary sediment	ANA, anti–dsDNA antibodies	Low C3, low C4	Granular immune deposits
IgA disease	Persistent microscopic hematuria with episodes of synpharyngitic macroscopic hematuria, with proteinuria, hypertension	IgA (increased in about half of cases)	Normal or increased	
Poststreptococcal glomerulonephritis	At 1 to 3 weeks after streptococcal pharyngitis or impetigo, macroscopic hematuria, edema, hypertension, oliguria	ASO, anti-DNase B antibodies	Low C3, normal C4	

ANA, antinuclear antibody; *anti-DNase B,* anti-deoxyribonuclease B antibody; *anti–dsDNA*, anti–double-stranded DNA antibody; anti-GBM, glomerular basement membrane antibody; *ASO*, antistreptolysin O antibody; *C-ANCA,* cytoplasmic antineutrophil cytoplasmic antibody; *IgA,* immunoglobulin A; *IgG,* immunoglobin G; *P-ANCA,* perinuclear antineutrophil cytoplasmic antibody; *SLE,* systemic lupus erythematosus; *WHO,* World Health Organization.
Ronco C et al: *Critical care nephrology,* ed 3, Philadelphia, 2019, Elsevier.

TABLE 2 Antigens Identified in Glomerulonephritis

Poststreptococcal GN	Streptococcal Pyrogenic Exotoxin B, Plasmin Receptor
Anti-GBM disease	α3 type IV collagen (likely induced by molecular mimicry)
IgA nephropathy	Immune complex of anti-glycan antibodies and complement components
Membranous nephropathy	Phospholipase A_2 receptor (idiopathic), neutral endopeptidase in podocyte (congenital), HBeAg (hepatitis associated)
Staphylococcus aureus–associated GN	*Staphylococcus* superantigens induce polyclonal response; not necessarily antigen in glomeruli
Membranoproliferative GN	HCV and HBsAg in hepatitis-associated MPGN
ANCA-associated vasculitis	Proteinase 3 (C-ANCA) and myeloperoxidase (P-ANCA) in neutrophils; antibodies to lysosome-associated membrane protein 2 (LAMP2) on endothelial cells (likely induced by molecular mimicry to fimbriated bacterial antigens)

ANCA, Antineutrophil cytoplasmic antibody; *GBM,* glomerular basement membrane; *GN,* glomerulonephritis; *HBeAg,* hepatitis B virus early antigen; *HBsAg,* hepatitis B surface antigen; *HCV,* hepatitis C virus; *IgA,* immunoglobulin A; *MPGN,* membranoproliferative glomerulonephritis.
Adapted from Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, Saunders.

- Treatment of streptococcal infection with penicillin (or erythromycin in penicillin-allergic patients). Hemodialysis in patients with diuretic-resistant volume overload, refractory hyperkalemia, uremic symptoms, and severe metabolic acidosis. Plasma exchange therapy for antibody removal for diffuse alveolar hemorrhage or rapidly progressive glomerulonephritis should be considered.

CHRONIC Rx

- Periodic monitoring of blood pressure, urinalysis, serum creatinine and blood urea nitrogen, serum albumin, and random urine protein-to-creatinine ratio.
- Angiotensin–converting-enzyme (ACE) inhibitors or angiotensin II receptor blockers (ARBs) to reduce proteinuria.
- Lipid management with statins and fibrates as indicated.
- Monitor for side effects related to immunosuppression such as infection, leukopenia and anemia, osteoporosis or osteopenia, gastrointestinal ulcers, high blood pressure, and tumors.
- Routine health maintenance with vaccinations for influenza and pneumococcus, age-appropriate vaccinations, and age-appropriate malignancy screening. Live vaccines are contraindicated in patients treated with immunosuppressants.

DISPOSITION

- Prognosis is generally correlated to initial serum creatinine and degree of renal fibrosis on biopsy.
- In general, prognosis is worse in patients with heavy albuminuria/proteinuria, low GFR at presentation, severe hypertension, and kidney biopsy-proven crescentic glomerulonephritis.
- Recovery of kidney function occurs within 8 to 12 weeks in 95% of patients with poststreptococcal glomerulonephritis.

REFERRAL

- Nephrology consultation for all patients with suspected glomerulonephritis. Urgent consultation is recommended if hyperkalemia, acidosis, or azotemia is present.

PEARLS & CONSIDERATIONS

COMMENTS

- Diagnosis of acute GN is established by kidney biopsy. Biopsy is indicated when the histologic diagnosis will alter the treatment plan, especially with systemic illnesses; significant proteinuria (>500 mg to 1 g per day); or increasing serum creatinine. A search for systemic illness, including infections, autoimmune disease, and malignancy is required with careful history, physical examination, and serologic tests. Some patients with suspected glomerulonephritis may not require a kidney biopsy because of the success of supportive therapies (e.g., infection-related GN).
- Nephrology consultation should be obtained before initiating immunosuppressive therapy. ACE inhibitor or ARB therapy is essential for proteinuria reduction, unless contraindicated. Spironolactone has been added to ACE inhibitor treatment for greater proteinuria reduction.
- Periodic monitoring for side effects of immunosuppressive drugs and complications of corticosteroids is necessary.
- Monitor lipids and treat persistent hyperlipidemia.

BASIC INFORMATION

DEFINITION

Acute kidney injury (AKI) is defined as a rapid impairment in kidney function that results in retention of products in the blood normally excreted by the kidneys. The decline in kidney function can result in volume overload and dysregulation of acid-base status and electrolytes. Current consensus criteria for diagnosis of AKI requires an increase in serum creatinine of 0.3 mg/dl within 48 hours or 1.5 times baseline serum creatinine over 7 days, and/or a decline in urine in output to <0.5 ml/kg/hour for 6 to 12 hours. AKI is further graded by severity as described in Table 1.

SYNONYMS

AKI
Acute renal failure (ARF)
Acute renal insufficiency syndrome
Acute kidney failure

ICD-10CM CODES

N17.9	Acute kidney failure, unspecified
N17.0	Acute kidney failure with tubular necrosis
N17.1	Acute kidney failure with acute cortical necrosis
N17.2	Acute kidney failure with medullary necrosis
N17.8	Other acute kidney failure
N99.0	Postprocedural (acute) (chronic) kidney failure
O90.4	Postpartum acute kidney failure

EPIDEMIOLOGY & DEMOGRAPHICS

- Using consensus criteria, an estimated 20% of hospitalized patients and nearly 60% of intensive care unit patients develop AKI.
- AKI occurs in 20% of patients with moderate sepsis and in >50% of patients with septic shock and positive blood cultures.
- Greater than 40% of hospital-associated AKI is iatrogenic.
- AKI in hospitalized patients is associated with increased hospital length-of-stay and cost.
- Most common cause of AKI in hospitalized patients is intrinsic kidney failure caused by acute tubular necrosis (ATN) and prerenal azotemia.
- Key risk factors for AKI include older age, preexisting chronic kidney disease, diabetes mellitus, and preexisting proteinuria.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Early or mild AKI may be asymptomatic
- Frequent presenting symptoms include weakness, anorexia, generalized malaise, and nausea
- Patients may develop oliguric or nonoliguric kidney injury
- Oliguria is defined as <400 to 500 ml of urine per 24 hours
- Physical examination should focus on evaluation of volume status
- Findings vary with duration and rapidity of onset of renal failure and underlying cause of AKI
- Peripheral edema from volume overload, heart failure, liver failure, or nephrotic syndrome
- Pulmonary edema
- Arrhythmias from electrolyte imbalances and metabolic acidosis
- Neurologic findings include altered mental status, delirium, lethargy, myoclonus, seizures, and flapping tremor (asterixis)
- Pruritus, uremic odor
- Flank pain
- Painless hematuria may be seen with glomerulonephritis, whereas painful hematuria is more consistent with obstructive uropathy
- Fasciculations, myoclonus, muscle cramps
- Pericardial effusion and/or pericardial rub
- Fever, skin rash, and arthralgia can be seen with systemic vasculitis
- Classic triad of fever, rash, and eosinophilia in the setting of AKI suggests allergic interstitial nephritis (AIN) and occurs in only 30% of cases. When considering AIN as the cause of AKI, a careful review of medications is required

ETIOLOGY

- **Prerenal:** Inadequate renal perfusion caused by hypovolemia, congestive heart failure (impaired cardiac output), cirrhosis (fluid third-spacing), sepsis (vasodilation), abdominal compartment syndrome, or other. Sixty percent of community-acquired cases of AKI are from prerenal conditions.
- **Postrenal:** Bladder outlet obstruction (prostatic enlargement, urethral fibrosis), ureteral obstruction (stones, bladder masses, retroperitoneal fibrosis, ureteral fibrosis), or renal vein occlusion. With two functioning kidneys, bilateral obstruction is usually required to cause significant AKI. Postrenal causes of AKI account for 5% to 15% of community-acquired AKI.
- **Intrinsic renal:** ATN, glomerulonephritis, AIN. Common causes of ATN include ischemia (e.g., hypotension or shock, postcardiac bypass, or aorta surgery), rhabdomyolysis, sepsis, drug toxicity (e.g., aminoglycosides, amphotericin, cisplatin), and iodinated radiocontrast nephropathy. Contrast-induced nephropathy is the third-most common cause of new-onset AKI in hospitalized patients. AIN can develop after exposure to a variety of medications, most commonly nonsteroidal antiinflammatory drugs, antibiotics, and proton pump inhibitors. Microvascular diseases that cause AKI include thrombotic microangiopathies (e.g., thrombotic thrombocytopenic purpura, classical and atypical hemolytic uremic syndrome, or preeclampsia) and cholesterol emboli.
- Causes of AKI are listed in Table 2.
- Nearly one third of cases of AKI may be prevented or mitigated by appropriate intervention.

DIAGNOSIS

Table 3 summarizes useful clinical features, urinary findings, and confirmatory tests in the differential diagnosis of AKI.

DIFFERENTIAL DIAGNOSIS

Refer to "Etiology." Diagnostic tests to distinguish prerenal and renal AKI are described in Table 4. A diagnostic approach to patients with suspected AKI is shown in Fig. 1.

LABORATORY TESTS

- Elevated serum creatinine: Rate of rise is approximately 0.5 to 2 mg/dl per day in complete kidney failure.
- Standard estimating equations for glomerular filtration rate (GFR) require steady-state creatinine levels and are not recommended to estimate GFR during AKI.
- Elevated blood urea nitrogen (BUN): BUN-to-creatinine ratio is commonly >20:1 in prerenal azotemia, postrenal azotemia, and acute glomerulonephritis.
- BUN-to-creatinine ratio is <20:1 in acute interstitial nephritis and ATN.
- Hyperkalemia, hyperphosphatemia, and metabolic acidosis are common.
- Hypocalcemia and hyponatremia or hypernatremia may occur, depending on underlying etiology.
- Urinalysis is the initial step of diagnostic evaluation. Prerenal and postrenal AKI are typically characterized by a normal urinalysis. Conversely, abnormal findings should prompt further work-up for specific intrinsic causes of AKI that may require urgent intervention. Hematuria and proteinuria imply glomerulonephritis, heavy

TABLE 1 Kidney Disease: Improving Global Outcomes (KDIGO) Criteria for Diagnosis of Acute Kidney Injury

AKI Definition and Staging		
Stage	**Serum Creatinine Criteria**	**Urine Output Criteria**
1	ΔS_{Cr} ≥0.3 mg/dl (30 μmol/L) or S_{Cr}≥1.5, <2.0 × baseline*	UO <0.5 ml/kg per hour × 6-12 h
2	S_{Cr} >2.0, <3.0 × baseline	UO <0.5 ml/kg per hour >12 h
3	S_{Cr} >3.0 × baseline or	
	S_{Cr} ≥4.0 mg/dl with an acute rise ≥0.5 mg/dl (50 μmol/L) or on renal replacement therapy	UO <0.3 ml/kg per hour × 24 h or anuria × 12 h

AKI, Acute kidney injury; *S_{Cr},* serum creatinine; *UO,* urinary output.
*To fulfill AKI criteria, an S_{Cr} rise of ≥0.3 mg/dl must occur within 48 hours; or increase to ≥1.5 times baseline SCr is known or presumed to have occurred within previous 7 days.
Adapted from KDIGO Clinical Practice Guideline for Acute Kidney Injury, 2012.

TABLE 2 Etiologies of Acute Kidney Injury

Prerenal Causes (Decreased Renal Blood Flow)	Intrinsic Renal Causes	Postrenal Causes
Hypovolemia	**Vascular: Large and Small Vessels**	**Ureteral Obstruction**
Renal losses (diuretics, osmotic agents, polyuria)	Trauma	Calculus
Gastrointestinal losses (vomiting, diarrhea)	Renal vein obstruction (thrombosis, ventilation with high-level PEEP, abdominal compartment syndrome)	Tumor (intrinsic or extrinsic)
Cutaneous losses (burns, exfoliative syndromes)	Microangiopathy (thrombotic thrombocytopenic purpura, hemolytic-uremic syndrome, disseminated intravascular coagulation, preeclampsia)	Fibrosis
Hemorrhage	Malignant hypertension	Ligation during pelvic surgery
Pancreatitis	Scleroderma renal crisis	**Bladder Neck Obstruction**
Decreased Cardiac Output	Transplant rejection	Benign prostatic hypertrophy
Congestive heart failure	Atheroembolic disease	Prostate cancer
Pulmonary embolism	**Glomerular**	Neurogenic bladder
Acute myocardial infarction	Antiglomerular basement membrane disease (Goodpasture syndrome)	Tricyclic antidepressants
Severe valvular heart disease	Antineutrophil cytoplasmic antibody-associated glomerulonephritis (Wegener granulomatosis)	Ganglionic blockers
Abdominal compartment syndrome	Immune complex glomerulonephritis, systemic lupus erythematosus, postinfectious cryoglobulinemia, primary membranoproliferative glomerulonephritis	Bladder tumor
Renal artery obstruction (stenosis, embolism, thrombosis, dissection)	**Tubular**	Calculus
Systemic Vasodilation	Ischemic	Hemorrhage/clot
Sepsis	Cytotoxic	**Urethral Obstruction**
Anaphylaxis	Heme pigment (rhabdomyolysis, intravascular hemolysis)	Strictures
Anesthetics	Crystals (tumor lysis syndrome, seizures, ethylene glycol poisoning, vitamin C megadose, acyclovir, indinavir, methotrexate)	Tumor
Drug overdose	Drugs (aminoglycosides, lithium, amphotericin B, pentamidine, cisplatin, ifosfamide, radiocontrast agents), synthetic cannabinoid use	Phimosis
Afferent Arteriolar Vasoconstriction	**Interstitial**	Renal calcinosis
Hypercalcemia	Drugs (penicillins, cephalosporins, NSAIDs, proton pump inhibitors, allopurinol, rifampin, indinavir, mesalamine, sulfonamides, trimethoprim)	Obstructed urinary catheter, ureteral stent, or ileal conduit
Drugs (NSAIDs, amphotericin B, calcineurin inhibitors, norepinephrine, radiocontrast agents, aminoglycosides)	Infection (pyelonephritis, viral infection)	Pelvic trauma, retroperitoneal hematoma
Hepatorenal syndrome	**Systemic Disease**	
Efferent arteriolar vasodilation (angiotensin converting enzyme inhibitors, aldosterone receptor blockers)	Sjögren syndrome, sarcoidosis, systemic lupus erythematosus, lymphoma, leukemia, tubulonephritis, uveitis	

NSAIDs, Nonsteroidal antiinflammatory drugs; *PEEP,* positive end-expiratory pressure.
Modified from Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.

(>3+) proteinuria is associated with nephrotic syndrome, and leukocyturia may signify AIN. Microscopic examination of urine sediment may facilitate diagnosis: Granular casts in ATN, dysmorphic red blood cells or red blood cell casts in acute glomerulonephritis, and white blood cell casts in AIN.

- In oliguric patients, obtain urine sodium and creatinine concentrations for determination of fractional excretion of sodium [$FE_{Na} = 100\% \times (U_{Na} \times P_{Cr})/(P_{Na} \times U_{Cr})$]. FE_{Na} <1% is seen in prerenal AKI and >1% in intrinsic AKI. FE_{Na} may be falsely elevated in patients taking diuretics or falsely low in several intrinsic renal conditions, including acute glomerulonephritis, contrast-induced nephropathy, and rhabdomyolysis.
- Fractional excretion of urea (FE_{Urea}) may be used to assess renal dysfunction in AKI. FE_{Urea} is calculated as [$FE_{Urea} = 100\% \times (U_{Urea} \times P_{Cr}) / (P_{Urea} \times U_{Cr})$]. FE_{Urea} <35% suggests prerenal acute kidney injury, and FE_{Urea} >50% indicates intrinsic AKI. FE_{Urea} is more useful than FE_{Na} during diuretic therapy.
- Urinary osmolarity is 250 to 300 mOsm/kg in ATN (isosthenuria), <400 mOsm/kg in postrenal azotemia, and >500 mOsm/kg in prerenal azotemia and acute glomerulonephritis.
- Blood cultures for suspected sepsis.
- In suspected glomerulonephritis (GN) (e.g., hematuria plus proteinuria, suggestive systemic clinical picture), additional serologic testing may be warranted. Abnormal liver function tests and elevated inflammatory markers are nonspecific. Immune complex deposition disorders (e.g., infectious GN, lupus nephritis, cryoglobulinemic vasculitis) are characterized by decreased complement (C3, C4) levels. Specific testing may include antinuclear antibodies (lupus), antineutrophil cytoplasmic antibodies (ANCA-associated vasculitis), anti-glomerular basement membrane antibodies (Goodpasture syndrome), and cryoglobulins. Kidney biopsy is frequently required for diagnostic confirmation.
- Creatinine kinase level is indicated if rhabdomyolysis is suspected; positive blood reaction on a urine dipstick with few or no red blood cells by microscopy may indicate myoglobinuria from rhabdomyolysis, but this finding is not invariable.
- Serum free light chain analysis, serum and urine protein electrophoresis, and serum and urine immunofixation electrophoresis for suspected multiple myeloma or other plasma cell dyscrasias. Myeloma can cause AKI via a variety of mechanisms, including tubular precipitation of light chains (cast nephropathy), hypercalcemia, and amyloidosis, among others.
- Kidney biopsy may be indicated in patients with intrinsic kidney failure when considering specific therapy. The major reasons for renal biopsy are for the differential diagnosis of nephrotic syndrome, distinguishing lupus vasculitis from other vasculitides, and lupus membranous nephropathy from idiopathic membranous nephropathy, confirmation of hereditary nephropathies based on ultrastructure, diagnosis of rapidly progressive glomerulonephritis, distinguishing AIN from ATN, and separation of primary glomerulonephritides. In addition to establishing a diagnosis, biopsy may determine renal prognosis and guide direction of management. Severe interstitial fibrosis is associated with poor renal outcomes.
- Biomarkers of kidney injury have been explored for earlier diagnosis of AKI or to separate intrinsic from prerenal causes. Candidate markers include cystatin C, neutrophil gelatinase-associated lipocalin (NGAL), kidney-injury molecule 1 (KIM-1), and liver fatty acid binding protein (LFABP).
- In 2014, tissue inhibitor of metalloproteinases and insulin-like growth-factor binding protein 7 (TIMP2*IGFBP7) became the first biomarker for AKI risk prediction approved in the U.S. However, there remains little published experience with this test, and the clinical role remains undefined.

IMAGING STUDIES

- ECG for arrhythmia detection, especially in hyperkalemia: Peaked T waves in precordial leads, widening QRS interval, and/or bradycardia with AV nodal blockade

TABLE 3 Useful Clinical Features, Urinary Findings, and Confirmatory Tests in the Differential Diagnosis of Acute Kidney Injury

Cause of Acute Kidney Injury	Some Suggestive Clinical Features	Typical Urinalysis Results	Some Confirmatory Tests
Prerenal azotemia	Evidence of true volume depletion (thirst, postural or absolute hypotension and tachycardia, low jugular venous pressure, dry mucous membranes and axillae, weight loss, fluid output greater than input) or decreased effective circulatory volume (e.g., heart failure, liver failure), treatment with NSAID, diuretic, or ACE inhibitor/ARB	Hyaline casts FE_{Na} <1% U_{Na} <10 mmol/L SG >1.018	Occasionally requires invasive hemodynamic monitoring; rapid resolution of AKI with restoration of renal perfusion
Diseases Involving Large Renal Vessels			
Renal artery thrombosis	History of atrial fibrillation or recent myocardial infarction, nausea, vomiting, flank or abdominal pain	Mild proteinuria Occasionally RBCs	Elevated LDH level with normal transaminase levels, renal arteriogram, MAG3 renal scan, MRA*
Atheroembolism	Usually age >50 yr, recent manipulation of aorta, retinal plaques, subcutaneous nodules, palpable purpura, livedo reticularis	Often normal Eosinophiluria Rarely casts	Eosinophilia, hypocomplementemia, skin biopsy, renal biopsy
Renal vein thrombosis	Evidence of nephrotic syndrome or pulmonary embolism, flank pain	Proteinuria, hematuria	Inferior venacavogram, Doppler flow studies, MRV*
Diseases of Small Renal Vessels and Glomeruli			
Glomerulonephritis or vasculitis	Compatible clinical history (e.g., recent infection), sinusitis, lung hemorrhage, rash or skin ulcers, arthralgias, hypertension, edema	RBC or granular casts, RBCs, white blood cells, proteinuria	Low complement levels; positive antineutrophil cytoplasmic antibodies, antiglomerular basement membrane antibodies, anti-streptolysin O antibodies, anti-DNase, cryoglobulins; renal biopsy
HUS/TTP	Compatible clinical history (e.g., recent gastrointestinal infection, cyclosporine, anovulants), pallor, ecchymoses, neurologic findings	May be normal, RBCs, mild proteinuria, rarely RBC or granular casts	Anemia, thrombocytopenia, schistocytes on peripheral blood smear, low haptoglobin level, increased LDH, renal biopsy
Malignant hypertension	Severe hypertension with headaches, cardiac failure, retinopathy, neurologic dysfunction, papilledema	May be normal, RBCs, mild proteinuria, rarely RBC casts	LVH by echocardiography or ECG, resolution of AKI with BP control
Ischemic or Nephrotoxic Acute Tubular Necrosis			
Ischemia	Recent hemorrhage, hypotension, surgery often in combination with vasoactive medication (e.g., ACE inhibitor, NSAID)	Muddy-brown granular or tubular epithelial cell casts FE_{Na} >1%, U_{Na} >20 mmol/L SG ≈ 1.010	Clinical assessment and urinalysis usually inform diagnosis
Exogenous toxin	Recent contrast medium-enhanced procedure; nephrotoxic medications; certain chemotherapeutic agents often with coexistent volume depletion, sepsis, or chronic kidney disease	Muddy-brown granular or tubular epithelial cell casts FE_{Na} >1%, U_{Na} >20 mmol/L SG ≈ 1.010	Clinical assessment and urinalysis usually inform diagnosis
Endogenous toxin	History suggestive of rhabdomyolysis (coma, seizures, drug abuse, trauma)	Urine supernatant tests positive for heme in absence of RBCs	Hyperkalemia, hyperphosphatemia, hypocalcemia, increased CK, myoglobin
	History suggestive of hemolysis (recent blood transfusion)	Urine supernatant pink and tests positive for heme in absence of RBCs	Hyperkalemia, hyperphosphatemia, hypocalcemia, hyperuricemia, and free circulating hemoglobin
	History suggestive of tumor lysis (recent chemotherapy), myeloma (bone pain), or ethylene glycol ingestion	Urate crystals, dipstick-negative proteinuria, oxalate crystals, respectively	Hyperuricemia, hyperkalemia, hyperphosphatemia (for tumor lysis); circulating or urinary monoclonal protein (for myeloma); toxicology screen, acidosis, osmolal gap (for ethylene glycol)
Diseases of the Tubulointerstitium			
Allergic interstitial nephritis	Recent ingestion of drug and fever, rash, loin pain, or arthralgias	White blood cell casts, white blood cells (frequently eosinophiluria), RBCs, rarely RBC casts, proteinuria (occasionally nephritic)	Systemic eosinophilia, renal biopsy
Acute bilateral pyelonephritis	Fever, flank pain and tenderness, toxic state	Leukocytes, occasionally white blood cell casts, RBCs, bacteria	Urine and blood cultures
Postrenal AKI	Abdominal and flank pain, palpable bladder	Frequently normal, hematuria if stones, prostatic hypertrophy	Plain abdominal radiography, renal ultrasonography, postvoid residual bladder volume, computed tomography, retrograde or antegrade pyelography

ACE, Angiotensin-converting enzyme; *AKI,* acute kidney injury; *ARB,* angiotensin receptor blocker; *BP,* blood pressure; *CK,* creatine kinase; *DNase,* deoxyribonuclease; *ECG,* electrocardiography; FE_{Na}, fractional excretion of sodium; *HUS,* hemolytic uremic syndrome; *LDH,* lactate dehydrogenase; *LVH,* left ventricular hypertrophy; *MAG3,* mercaptoacetyltriglycine; *MRA,* magnetic resonance angiography; *MRV,* magnetic resonance venography; *NSAID,* nonsteroidal antiinflammatory drug; *RBC,* red blood cell; *SG,* specific gravity; *TTP,* thrombotic thrombocytopenic purpura; U_{Na}, urinary sodium concentration.

*Contrast-enhanced MRA and MRV should be used with extreme caution in patients with AKI.

TABLE 4 Diagnostic Tests to Distinguish between Prerenal and Renal Acute Kidney Injury

Index	Prerenal Causes	Renal Causes
FE_{Na}	<1%	>2%
Urine sodium	<10 mmol/L	>40 mmol/L
Urine/plasma osmolality	>1.5	1 to 1.5
Renal failure index	<1	>2
BUN/creatinine ratio	>20	<10

BUN, Blood urea nitrogen; *FE_{Na},* fractional excretion of sodium. Calculation of FE_{Na}: (Urine sodium × Plasma creatinine)/(Plasma sodium × Serum creatinine) × 100. Renal failure index: (Urine sodium × Urine creatinine)/Plasma creatinine.
From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.

- Chest radiograph to detect signs of congestive heart failure and pulmonary renal syndromes, which frequently present with alveolar hemorrhage (Goodpasture syndrome, ANCA-associated vasculitis)
- Kidney ultrasonography to determine kidney sizes (distinguishes acute from chronic kidney disease), presence of obstruction, and renal vascular status (Doppler study)
- Bladder scan to assess post-void residual urine when urinary obstruction is suspected
- Computed tomography (CT) with radiocontrast administration is typically avoided in AKI. However, unenhanced CT scans may identify obstructing ureteral stones

Rx TREATMENT

Management of AKI depends on the underlying etiology. Some conditions (e.g., glomerulonephritis) require specific therapy, but the general focus of treatment for established AKI is supportive care and limiting additional injury. Fig. 2 illustrates an algorithm for management of AKI.

NONPHARMACOLOGIC THERAPY

- Withdraw nephrotoxic medications.
- Evaluate volume status and correct hypovolemia. Goal of therapy is to increase cardiac output and improve tissue perfusion.
- Among patients in intensive care units, utilize hemodynamic tools to avoid excessive fluid administration in patients who are non-volume responsive.
- Dietary modification: (1) Energy prescription of 29 to 36 Kcal/kg per day, (2) potassium restriction (60 mEq per day), (3) sodium restriction (90 mEq per day), (4) phosphorus restriction (800 mg per day), and (5) protein supplementation of 0.6 to 1.4 g/kg per day depending on requirement for dialysis.
- Daily weight to monitor for fluid retention (in addition to intake and output measurement).
- Modification of drug dosages or schedules of renally excreted medications. Dosing should consider the trajectory of renal function (during evolving and recovering AKI) and may require additional adjustments in patients who require dialysis.

ACUTE GENERAL Rx

- Correct electrolyte abnormalities and metabolic acidosis.
- Administer loop diuretics for volume overload.
- Administer vasopressors or vasodilators, when appropriate, to optimize cardiac output in congestive heart failure.

Specific treatment is variable and dependent on etiology of AKI:

- Prerenal: IV volume expansion with isotonic solutions in hypovolemic patients or those with shock.
- Intrinsic kidney failure: Discontinue all potential nephrotoxins and treat condition(s) causing kidney failure. In severe AIN cases, consider a trial of corticosteroids. For acute noninfectious glomerulonephritis, high-dose pulse corticosteroids are first-line therapy, typically in conjunction with other immunomodulatory therapy and plasma exchange, depending on the clinical scenario.
- Postrenal: Eliminate cause of obstruction. Immediate bladder catheter insertion for suspected bladder outlet obstruction. Percutaneous nephrostomy tubes or ureteral stents may be required for upper tract obstruction.
- Hyperkalemia-related ECG changes: IV (intravenous) calcium if electrocardiographic changes present; IV insulin and/or glucose to shift potassium into cells; and IV bicarbonate therapy when metabolic acidosis is present to shift potassium into cells. These three treatments are temporary, and definitive therapy requires potassium removal via the gastrointestinal tract (potassium-binding agents or cathartics) or urinary tract by diuretics or dialytic therapy.

Dialysis in AKI:

- General indications for initiation of dialysis during AKI
  1. Uremic symptoms (encephalopathy, pericarditis)
  2. Extracellular fluid volume overload refractory to medical management
  3. Severe acid-base imbalance refractory to medical management
  4. Significant electrolyte derangement (e.g., hyperkalemia, hyponatremia) refractory to medical management
- Among critically ill patients, dialysis may be warranted even in the absence of the previous indications. Optimal timing of initiation of dialysis remains controversial and is not solely dependent on previous metabolic parameters. Recent clinical trials have not shown early dialysis in AKI to carry a mortality benefit.
- Intermittent hemodialysis (IHD) and continuous renal replacement therapy (CRRT) have similar outcomes for patients with AKI. However, CRRT is associated with greater hemodynamic stability and fluid removal compared to conventional IHD. CRRT is the preferred modality in critically ill patients with hemodynamic instability.

ADJUNCTIVE Rx

- Monitoring of renal function parameters and electrolytes.
- Renally excreted drugs are adjusted according to creatinine clearance or glomerular filtration rate to prevent further kidney damage or other medication-related toxicities.
- Prevent further renal insult with appropriate volume expansion, particularly before contrast administration, and avoid nephrotoxic agents. Volume expansion with isotonic solutions is more effective than hydration with hypotonic solutions. Isotonic saline or bicarbonate-containing solutions are effective, with or without concomitant N-acetylcysteine prophylaxis, which has shown conflicting results regarding its ability to reduce the risk of iodinated radiocontrast-induced nephropathy.
- Renal function recovery (ability to discontinue dialysis) varies from 50% to 75% in AKI survivors. Preexisting CKD, longer duration of dialysis dependence, congestive heart failure, and older age are negative prognostic factors for renal function recovery.
- Overall mortality rate in AKI is nearly 25% and approaches 50% to 60% in patients who require acute dialysis.
- The combination of AKI and sepsis is associated with a mortality rate as high as 70%.

PEARLS & CONSIDERATIONS

- Patients with AKI are susceptible to infections and sepsis.
- In patients with community-acquired AKI, it is important to obtain a thorough medication history, including nonprescription medications or supplements.
- AKI survivors are at risk for development of CKD, and follow-up with monitoring of kidney function is essential even after apparent renal recovery.

BASIC INFORMATION

DEFINITION

Acute liver failure (ALF) is defined as the constellation of acute (<26 wk) severe hepatic injury; synthetic liver dysfunction, specifically coagulopathy (international normalized ratio [INR] >1.5); and any degree of mental alteration (encephalopathy) in a patient without preexisting liver disease, in the absence of acute alcoholic hepatitis. ALF can also be diagnosed in patients with preexisting liver disease, such as Wilson disease, vertically acquired hepatitis B, and autoimmune hepatitis, provided that diagnosis of these conditions was made within the preceding 26 weeks. Box 1 summarizes classifications of acute liver failure.

SYNONYMS

Fulminant hepatic failure
Fulminant hepatitis
Fulminant hepatic necrosis
Acute hepatic necrosis
Acute and subacute necrosis of liver
ALF

ICD-10CM CODES

K72	Hepatic failure, not elsewhere classified
K72.0	Acute and subacute hepatic failure
K72.00	Acute and subacute hepatic failure without coma
K72.01	Acute and subacute hepatic failure with coma

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Affects approximately 2000 people/yr in U.S. and 1-8 people per million population in the U.K.

PREDOMINANT SEX AND AGE: Seen more often in women (90% of cases), average age 38 yr

RISK FACTORS:

- Intentional or inadvertent drug overdose
- Risk factors for viral hepatitis:
  1. Intravenous drug use
  2. Occupational exposure to blood or body fluids
  3. Blood transfusions
  4. Hemodialysis
  5. Intranasal cocaine use
  6. Imprisonment
  7. Travel to endemic hepatitis areas
- Previous alcohol use
- Hepatotoxic medications
- Critical illness

ETIOLOGY

- Common causes in the Western world:
  1. Acetaminophen toxicity (46%)
  2. Indeterminate (14%)
  3. Idiosyncratic drug reaction (12%)
  4. Viral hepatitis (A, B) (10%)

Other, more rare causes include alcoholic hepatitis, autoimmune hepatitis, Wilson disease, ischemic hepatopathy, Budd-Chiari syndrome, acute fatty liver of pregnancy, venoocclusive disease, toxin ingestion (e.g., mushroom poisoning *[Amanita phalloides]*), sepsis, infiltrative malignancy (breast cancer, lymphoma, myeloma, melanoma, small cell lung cancer), and other viruses (adenovirus, hepatitis E, HSV). Box 2 summarizes possible etiologies of liver failure.

CLINICIAN PRESENTATION & PHYSICAL FINDINGS

- **CLINICAL PRESENTATION** Initial symptoms of ALF are mostly nonspecific, such as fatigue, lethargy, anorexia, and nausea/vomiting. Pruritus, jaundice, and right upper quadrant abdominal pain and distention may be present.
- **PHYSICAL EXAMINATION** Findings include, by definition, abnormal neurologic findings of encephalopathy (see Table 1). Other findings may include jaundice, asterixis, hepatomegaly, decreased hepatic mass on percussion, and ascites. Multisystem organ failure can ensue. In rare cases, as the hepatic encephalopathy progresses, cerebral edema and increased intracranial pressure can occur, with abnormal pupillary exam findings, hypertension, bradycardia, respiratory depression (Cushing's triad), seizures, and loss of brain stem reflexes. Vesicular skin lesions are suggestive of herpes simplex virus (HSV).
- Family history of unexplained liver disease/cirrhosis should prompt slit lamp ocular examination for the identification of Kayser-Fleischer rings (copper rings around the iris seen in Wilson disease).

LABORATORY FINDINGS

- Patients with ALF typically have a prolonged prothrombin time (INR >1.5), elevated transaminases, and elevated bilirubin, and may have a low platelet count (<150,000).
- Other possible laboratory findings can include an elevated BUN/creatinine (studies show 30% to 50% also have acute kidney injury), hypoglycemia (impairment of gluconeogenesis), hypophosphatemia, hypomagnesemia, hypokalemia, metabolic acidosis or respiratory alkalosis, elevated LDH, and elevated ammonia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Severe acute hepatitis, also known as acute liver injury (including alcoholic hepatitis): Jaundice and coagulopathy without encephalopathy
- Acute on chronic liver failure (in patients with liver disease duration >26 weeks)
- Cirrhosis (includes decompensated cirrhosis)
- Hepatocellular carcinoma

WORKUP (BOX 3)

- Fig. 1 describes an algorithm for evaluation of acute liver failure.
- Clinical history is critical, but in the case of patients with severe encephalopathy, the history may be limited, and efforts should be made to obtain information from the patient's family. Important history components include medication use (6-month history of prescriptions, over-the-counter medications, herbal supplements), alcohol use, recreational drug use, prior symptoms of jaundice, onset of symptoms, history of depression and suicide attempts, recent travel to endemic areas of viral hepatitis, sexual exposures, previous blood transfusions, family history of liver failure/disease, history of malignancy, or hypercoagulable state.

BOX 1 Classifications of Acute Liver Failure

Trey and Davidson
Fulminant hepatic failure: Development of HE within 8 weeks of onset of symptoms

British Classification
Acute liver failure (includes only patients with encephalopathy)

Subclassification Depending on the Interval between the Onset of Jaundice and HE
- Hyperacute liver failure: 0 to 7 days
- Acute liver failure: 8 to 28 days
- Subacute liver failure: 29 to 72 days
- Late-onset acute liver failure: 56 to 182 days

French Classification
Acute hepatic failure: A rapidly developing impairment of liver function
Severe acute hepatic failure: Prothrombin time or factor V concentration below 50% of normal with or without HE

Subclassification
- Fulminant hepatic failure: HE within 2 weeks of onset of jaundice
- Subfulminant hepatic failure: HE between 3 and 12 weeks of onset of jaundice

International Association for the Study of Acute Liver Failure
Acute liver failure (occurrence of HE within 4 weeks after onset of symptoms)

Subclassification
- Acute liver failure—hyperacute: Within 10 days
- Acute liver failure—fulminant: 10 to 30 days
- Acute liver failure—not otherwise specified
- Subacute liver failure (development of ascites and/or HE from 5 to 24 weeks after onset of symptoms)

HE, Hepatic encephalopathy.

BOX 2 Etiologic Classification of Acute Liver Failure

Acetaminophen Toxicity
Idiosyncratic Drug Injury

Infrequent Agents
Isoniazid
Valproate
Halothane
Phenytoin
Sulfonamide
Propylthiouracil
Amiodarone
Disulfiram
Dapsone
Bromfenac
Troglitazone
Zidovudine
Lamivudine
Lamotrigine
Gatifloxacin
Methotrexate

Miscellaneous Agents
Ecstasy
Cocaine
Phencyclidine

Rare Agents
Carbamazepine
Ofloxacin
Ketoconazole
Lisinopril
Nicotinic acid
Labetalol
Etoposide
Imipramine
Interferon alfa
Flutamide
Tolcapone
Nefazodone
Oral contraceptives

Combination Agents with Enhanced Hepatotoxicity
Alcohol-acetaminophen
Trimethoprim-sulfamethoxazole
Rifampicin-isoniazid
Amoxicillin-clavulanic acid

Viral Hepatitides
Hepatitis A, B, C, D, E, G
Human herpesvirus
Cytomegalovirus
Epstein-Barr virus
Herpes simplex virus
Varicella zoster virus
Paramyxovirus
Parvovirus B19
Adenovirus
Togavirus
Parvovirus
SEN virus
TT virus
Yellow fever virus

Toxins
CCl_4
Amanita phalloides
Yellow phosphorus
Herbal products

Vascular
Ischemic
Veno-occlusive disease
Budd-Chiari syndrome
Malignant infiltration
Non-Hodgkin's lymphoma

Miscellaneous
Wilson disease
Autoimmune hepatitis
Acute fatty liver of pregnancy
Reye syndrome

CCl4, Carbon tetrachloride.
From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

TABLE 1 Grades of Encephalopathy

Grade	Description
I	Changes in behavior with minimal change in level of consciousness (mild confusion, slurred speech, disordered sleep)
II	Gross disorientation, drowsiness, possibly asterixis, inappropriate behavior
III	Marked confusion (stupor), incoherent speech, sleeping most of the time but rousable to vocal stimuli
IV	Comatose, unresponsiveness to pain, decorticate or decerebrate posturing

- Physical examination should include mental status examination. Grading of hepatic encephalopathy should be performed (Table 1). Perform an asterixis maneuver, consider psychometric tests (i.e., number connection test) to detect subtle degree of encephalopathy. Looking for stigmata of chronic liver disease is also important as their presence has different diagnostic and management implications.
- Laboratory evaluation should be targeted to assess the severity of ALF, as well as its etiology. Early testing includes complete blood count, liver function tests (LFTs) including prothrombin time and INR, chemistry panel (sodium, potassium, chloride, bicarbonate, BUN, creatinine, glucose, magnesium, phosphate, calcium), arterial blood gas, arterial lactate, blood type and screen, acetaminophen level, ethanol level, toxicology screen, viral hepatitis serologies (hepatitis A IgM, hepatitis B surface antigen, anti-hepatitis B core IgM, anti-hepatitis C antibody [IgM and IgG]), hepatitis C viral load (HCV RNA), anti-hepatitis E IgM and IgG, HSV-1 IgM and HSV PCR, EBV DNA PCR, CMV DNA PCR, anti-hepatitis D IgM and IgG, hepatitis D viral load (HDV RNA), ceruloplasmin level (as well as serum copper and 24-hour urine copper if high suspicion), pregnancy test, arterial ammonia level, autoimmune markers (ANA, ASMA, anti-LKM-1, total IgG levels), HIV-1, HIV-2, amylase, lipase. Imaging studies include abdominal ultrasound with Doppler to evaluate for Budd-Chiari syndrome, portal hypertension, hepatic congestion, and hepatic steatosis. Cirrhosis cannot be diagnosed in the setting of ALF, as the liver may appear nodular in ALF due to massive necrosis; consider cross-sectional imaging of the liver (triphasic CT, MRCP, or MRI with gadolinium). CT or MRI of the head should be considered to ensure no other causes for altered mental status.
- Prompt liver biopsy (via transjugular approach to decrease risk of bleeding) should be performed in cases in which:
  1. The etiology is unknown after the initial workup; *or*
  2. Etiology is thought to be secondary to autoimmune hepatitis, malignancy, or HSV.

BOX 3 Investigations in Fulminant Hepatic Failure

Baseline essential investigations
Biochemistry
- Bilirubin, transaminases
- Alkaline phosphatase
- Albumin
- Urea and electrolytes
- Creatinine
- Calcium, phosphate
- Ammonia
- Acid-base, lactate
- Glucose

Hematology
- Full blood count, platelets
- PT, PTT
- Factors V or VII
- Blood group cross-match
  Septic screen

Omitting lumbar puncture
- Radiology
- Chest radiograph
- Abdominal ultrasound
- Head CT scan or MRI

Neurophysiology
- Electroencephalogram

Diagnostic investigations
  Serum
- Acetaminophen levels
- Cu, ceruloplasmin (>3 yr)
- Autoantibodies
- Immunoglobulins
- Amino acids
- Lactate
- Pyruvate
- Hepatitis A, B, C, E
- EBV, CMV, HSV viral loads
- Other viruses

Urine
- Toxic metabolites
- Amino acids, succinylacetone
- Organic acids
- Reducing sugars

CMV, Cytomegalovirus; *CT,* computed tomography; *EBV,* Epstein-Barr virus; *HSV,* herpes simplex virus; *PT,* prothrombin time; *PTT,* partial thromboplastin time.
From Fuhrman BP, Zimmerman JJ: *Fuhrman and Zimmerman's pediatric critical care,* ed 4, Philadelphia, 2011, Mosby.

COMPLICATIONS

Complications or progression of liver failure may result in cerebral edema due to increased intracranial pressure (in up to 40% of patients), high-output cardiac failure, hypoglycemia, lactic acidosis, acute respiratory distress syndrome,

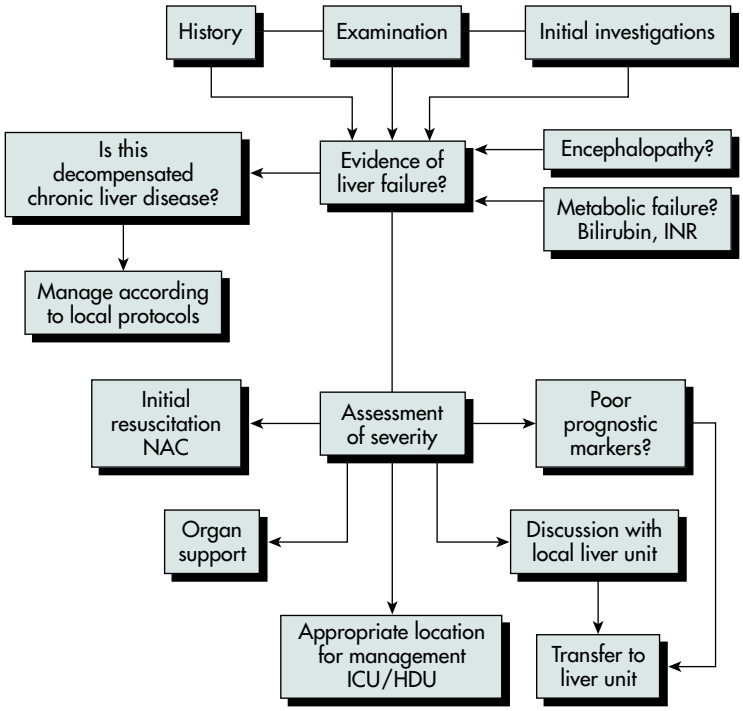

FIG. 1 Initial management of a patient presenting with liver failure. *HDU,* High-dependency unit; *ICU,* intensive care unit; *INR,* international normalized ratio; *NAC,* N-acetylcysteine. (From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.)

upper gastrointestinal hemorrhage (in 1.5% of patients), infectious disease from impaired leukocyte function (in nearly 80% patients), acute kidney injury, and pancreatitis (particularly in acetaminophen-induced ALF). Hypotension can occur due to decreased oral intake as well as extravasation of fluid into extravascular space.

Rx TREATMENT (BOXES 4 AND 5)

NONPHARMACOLOGIC THERAPY

- Initial treatment should focus on the patient's mental status.
  1. Grade I encephalopathy may be managed on a medical ward (neuro vital signs q4h).
  2. Grade II, III, and IV encephalopathy should be managed in ICU (elevate head of the bed to 30 degrees).
  3. Decrease stimulation (dimly lit, quiet room, no audible monitor alarms).
- A liver specialist should be notified urgently, and arrangements should be made for imminent transfer to a transplant center.
- Nutritional support should be initiated early. A daily intake goal of 60 g of protein is recommended to prevent catabolism of protein stores. Enteral feeding should be initiated in patients with grade III or IV encephalopathy.
- Fluid support should be initiated if patient is not tolerating oral intake, or signs of hypoperfusion are present. Crystalloid solutions (normal saline in hypotensive patients, ½ normal saline + 75 mEq/L $NaCO_3$ in acidotic patients, normal saline + dextrose in hypoglycemic patients) can be used.

MONITORING

- In patients with high-grade HE awaiting transplant, intracranial pressure (ICP) monitoring is recommended in centers with expertise in ICP monitoring.
- Neurologic examination every 1 to 4 hours is recommended in the absence of ICP monitoring.
- Patients with suspected acetaminophen toxicity should have LFTs monitored every 12 hr. Otherwise, LFTs can be monitored daily.
- Chemistry panels and PT/INR should be monitored every 8 to 12 hr. Correction of coagulopathy should be avoided because it can interfere with assessment of liver function. In the setting of life-threatening bleeding, fresh frozen plasma (FFP) and recombinant factor VIIa can be considered.
- Glucose finger sticks should be checked every 4 hr initially to evaluate for hypoglycemia. If hypoglycemia is detected, dextrose should be added to crystalloid solution.
- Because of the increased risk of infection, daily urine, sputum, and blood cultures, as well as chest radiographs, should be checked in the absence of signs or symptoms of infection.

PHARMACOLOGIC TREATMENT

- If acetaminophen is the known or suspected cause, an IV acetylcysteine protocol must be initiated. *N*-acetylcysteine is not harmful and dramatically alters the course in acetaminophen toxicity, so there should be a low threshold to start, particularly in young patients or those with no known cause of ALF.

BOX 4 Management of Fulminant Hepatic Failure

No sedation except for procedures
Minimal handling
Enteric precautions until infection ruled out
Monitor:
- Heart and respiratory rate
- Arterial BP, CVP
- Core/toe temperature
- Neurologic observations
- Gastric pH (>5.0)
- Blood glucose (>4 mmol/L)
- Acid-base
- Electrolytes
- PT, PTT

Fluid balance
- 75% maintenance
- Dextrose 10% to 50% (provide 6 to 10 mg/kg/min)
- Sodium (0.5 to 1 mmol/L)
- Potassium (2 to 4 mmol/L)

Maintain circulating volume with colloid/FFP
Coagulation support only if required
Drugs
- Vitamin K
- H_2 antagonist
- Antacids
- Lactulose
- *N*-acetylcysteine for acetaminophen toxicity
- Broad-spectrum antibiotics
- Antifungals

Nutrition
- Enteral feeding (1 to 2 g protein/kg/day)
- PN if ventilated

BP, Blood pressure; *CVP,* central venous pressure; *FFP,* fresh frozen plasma; *PN,* parenteral nutrition; *PT,* prothrombin time; *PTT,* partial thromboplastin time.

From Fuhrman BP, Zimmerman JJ: *Fuhrman and Zimmerman's pediatric critical care,* ed 4, Philadelphia, 2011, Mosby.

- The 20-hr protocol is:
  1. Initial loading dose of 150 mg/kg IV given over 60 min followed by;
  2. 12.5 mg/kg IV/hr over 4 hr followed by;
  3. 6.25 mg/kg IV/hr for 16 hr.
- A repeat acetaminophen level and ALT should be checked at hour 18 of NAC treatment. If either the acetaminophen level or the ALT is elevated, the 16-hour portion of treatment (6.25 mg/kg) should be extended and another ALT, INR, or acetaminophen level should be checked every 12 hr. The acetylcysteine can be stopped once the acetaminophen level is undetectable, INR <2, or ALT is shown to be either normal or decreasing. Additional information on acetaminophen overdose is available in the topic "Acetaminophen Poisoning."
- *N*-acetylcysteine therapy outside of acetaminophen poisoning has been investigated and may be beneficial; however, its routine use is not currently recommended by practice guidelines and is center specific.
- Patients should be placed on stress ulcer prophylaxis given the risk of gastrointestinal bleeding.

BOX 5 Hepatic Replacement Therapeutic Options Available to Patients with Fulminant Hepatic Failure

Liver Transplantation
- Cadaveric transplantation
- Whole liver
- Reduced-size liver
- Split liver
- Auxiliary partial liver
- Orthotopic position
- Heterotopic position
- Auxiliary whole liver
- Living-related transplantation
- Left lateral segment
- Left lobe
- Extended left lobe
- Right lobe

Artificial Liver Assist Devices
- Non–cell-based systems
- Charcoal hemoperfusion
- High-volume plasmapheresis
- Continuous high-frequency hemodiafiltration
- Molecular adsorbent recirculating system (MARS)
- Cell-based systems (bioartificial liver assist devices)
- Primary porcine hepatocytes
- Human hepatoblastoma cells
- Extracorporeal liver assist device (ELAD)

Hepatocyte Transplantation

From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, Saunders.

- Broad-spectrum antibiotics should be started immediately if infection is suspected. Sources usually include respiratory, urinary, and blood; there is no evidence for empiric antibiotic treatment. Antifungals should be initiated if no initial improvement with antibiotics occurs.
- Norepinephrine is the initial vasopressor of choice; vasopressin can be added as a second pressor to maintain MAP >75 mm Hg. Persistent hypotension despite fluid resuscitation and pressor support should prompt concern for adrenal insufficiency.
- Lactulose is not routinely recommended for encephalopathy treatment; neomycin should be avoided due to concerns of nephrotoxicity.
- Sedative medications should also be avoided as they are not cleared well and may mask signs of worsening encephalopathy or cerebral edema.
- If cerebral edema develops leading to increased ICP, intravenous mannitol is recommended to reduce cerebral edema transiently. Prophylactic hyperventilation is not recommended in patients with ALF.

TABLE 2 King's College Hospital Criteria for Liver Transplantation in Acute Liver Failure

Acetaminophen-Induced Acute Liver Failure	Non–Acetaminophen-Induced Acute Liver Failure
Arterial pH <7.3 (irrespective of grade of encephalopathy) *OR* Grade III or IV encephalopathy *and* Prothrombin time >100 sec *and* Serum creatinine >3.4 mg/dl	Prothrombin time >100 sec (irrespective of grade of encephalopathy *OR* Any of three of the following variables (irrespective of grade of encephalopathy): 1. Age <10 yr or >40 yr 2. Etiology: Non-A hepatitis, non-B hepatitis, halothane hepatitis, idiosyncratic drug reactions 3. Duration of jaundice before onset of encephalopathy >7 days 4. Prothrombin time >50 sec 5. Serum bilirubin >18 mg/dl

Sec, Seconds.

Liver support systems:
- Liver support systems have been trialed either to support the patient until the liver recovers or as a bridge to liver transplantation.
- Plasmapheresis can improve hepatic encephalopathy, but no survival benefit has been shown.
- The molecular absorbents recirculation system (MARS) allows albumin-bound toxins to be removed. But this too has failed to show a survival benefit in patients with ALF.

PROGNOSIS

- Overall mortality from ALF is 30% to 40% and improved significantly over the last 20 yr.
- Transplant-free survival in ALF in the setting of acetaminophen, hepatitis A, shock liver, and pregnancy-related disease is >50%; for all other causes of ALF, transplant-free survival is <25%.
- Multiple models have been developed to predict spontaneous recovery in ALF patients (King's College criteria, Clichy criteria, MELD score, APACHE II score).
- The King's College criteria form the basis of the model most commonly used for prognostication (Table 2).
- Transplantation:
  1. Patients with ALF are given the highest priority for liver transplantation.
  2. Contraindications to listing include medical history of psychiatric illness severe enough to affect patients' survival or likelihood of compliance with medications, active sepsis, severe medical comorbidities including malignancy, increasing dependence on ventilator/inotropic support, acute substance abuse, previous episodes of self-harm (>5 episodes), refractory mental illness.
  3. For patients with alcoholic liver disease, many centers require a 6-month abstinence period, but several transplant centers in North America and Europe have transplanted selected patients with alcoholic hepatitis who were unlikely to survive 6 months.
  4. Mortality on the waiting list is 25%; 1-yr and 5-yr survival after transplantation is 73% and 67%, respectively.
  5. Various prognostic criteria used for liver transplantation in patients with fulminant hepatic failure are summarized in Box E6.

PEARLS & CONSIDERATIONS

- ALF is defined as severe hepatic injury (as evidenced by elevated liver enzymes) with INR >1.5 and hepatic encephalopathy occurring <26 wk before presentation in a patient with no prior history of liver disease.
- Close to half of ALF is caused by drug ingestion, usually acetaminophen.
- Given the potential rapidity of deterioration, referral must be made as soon as possible to a liver transplant center.
- There should be a low threshold to start *N*-acetylcysteine.
- Coagulopathy should not be corrected unless life-threatening bleeding occurs or it is recommended by the liver transplant hepatologist.

BOX E6 Various Prognostic Criteria Used for Liver Transplantation in Patients with Fulminant Hepatic Failure

King's College Criteria

Acetaminophen Overdose

- Arterial pH <7.3 (irrespective of grade of encephalopathy)
  or
- PT >100 sec (INR >6.5) *and*
- Serum creatinine >3.4 mg/dl (>300 μmol/L) *and*
- Patients with grade III and IV hepatic encephalopathy

Non–Acetaminophen-Induced Liver Injury

Acute form (delayed jaundice-encephalopathy <7 days):

- PT >100 sec (INR >6.5) (irrespective of grade of encephalopathy) or any three of the following variables:
- Aged <10 or >40 yr
- Non-A, non-B hepatitis, halothane hepatitis, idiosyncratic drug reactions
- Subacute form: Delayed encephalopathy >7 days
- Serum bilirubin 17.4 mg/dl (300 μmol/L)
- PT >50 sec

Clichy Criteria

- Grade III or IV encephalopathy
  and
- Factor V <20% in patients <30 yr
  or
- Factor V <30% in patients >30 yr

Serum Gc Globulin Levels

Decreasing Gc levels due to dying hepatocytes

Serum α-Fetoprotein Levels

Serial increase from day 1 to day 3 has been correlated with survival

Liver Biopsy

70% necrosis is discriminant of 90% mortality

Gc, Plasma group-specific component protein; *INR,* international normalized ratio; *PT,* prothrombin time.

BASIC INFORMATION

DEFINITION

Acute lower gastrointestinal bleeding is defined as sudden colonic blood loss.

SYNONYMS

Acute colonic bleeding
Gastrointestinal hemorrhage
Melena
Hematochezia

ICD-10CM CODES

K92.2 Gastrointestinal hemorrhage, unspecified
K92.1 Melena
K62.5 Hemorrhage of rectum and anus

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Annual incidence in U.S. of lower gastrointestinal (GI) bleeding is 72/100,000.
- Annual incidence in U.S. of hospitalization is 36/100,000 (about half of that for upper GI bleeding).

PEAK INCIDENCE: The rate of lower GI bleeding, including that necessitating hospitalization, is higher in the elderly.

PREDOMINANT SEX AND AGE: 24.2/100,000 in males versus 17.2/100,000 in females. This increases 200-fold by the ninth decade of life

RISK FACTORS: Risk factors include NSAID use, aspirin use, alcohol abuse, GI malignancy, atrial fibrillation, coagulopathies, prior GI bleed, cirrhosis, constipation, congenital malformations, radiation exposure, recent infectious illness, recent travel, abdominal aortic aneurysm (AAA) repair, and inflammatory bowel disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Attention should be paid in the history to details suggesting the location and etiology of the bleed. For instance, weight loss and abdominal pain suggest inflammatory bowel disease; recent AAA repair, especially with history of a sentinel bleed, raises suspicion for aortoenteric fistula; a history of cirrhosis suggests bleeding from portal hypertension, e.g., varices. Bright red blood is typically from a brisk upper GI bleed, distal colon, or anorectal disease. Melena arises from the upper GI tract, small bowel, or proximal colon. Take a detailed medication history, noting NSAIDs or other drugs that may cause or mimic GI bleeding as well as beta blockers that may mask tachycardia in the setting of significant blood loss.
- The clinician should first and foremost check vital signs, including orthostatics, if stable. Perform ABCs as indicated. Check for pallor and signs of volume depletion, such as delayed capillary refill and skin tenting. Observe for stigmata of liver disease, such as telangiectasias and jaundice. Auscultate for bowel sounds. Absence of bowel sounds may indicate perforation. Palpate the abdomen for pain, masses, and hepatosplenomegaly. Rectal exam should be performed, noting the presence of blood, rate of bleeding, masses, fissures, hemorrhoids, tenderness, and skin changes. If no gross bleed is seen, perform hemoccult testing. Ensure that the bleeding is, in fact, gastrointestinal, excluding hematuria, vaginal bleeding, and wounds.

ETIOLOGY

Diverticulosis is the most common cause of lower GI bleeding at 30%. Internal hemorrhoids are the second most common cause. 15% of lower GI bleeds are due to upper GI bleeding.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Upper GI bleed
- Diverticulosis
- Diverticulitis
- Ischemic colitis
- Postpolypectomy bleeding
- Vascular ectasias (angiodysplasia, arteriovenous malformation)
- Anal fissure
- Rectal ulcer
- Colonic polyps
- Advanced neoplasms
- Hemorrhoids
- Intussusception
- Coagulopathies
- Infectious colitis (*E. coli, Shigella, Salmonella, Giardia*)
- Autoimmune (hemolytic uremic syndrome)
- Radiation colitis or proctitis
- Aortoenteric fistula
- Vasculitis
- Inflammatory (ulcerative colitis, Crohn disease)
- Colonic varices
- Drugs (iron, NSAIDs)
- Foreign body

WORKUP

Establish large-bore intravenous access. If the patient has significant hematochezia without hematemesis, consider performing nasogastric lavage to evaluate for upper GI bleeding. An algorithm for the management of severe hematochezia is illustrated in Fig. 1.

LABORATORY TESTS

- Complete blood count may reveal anemia and/or thrombocytopenia. The hematocrit and hemoglobin should generally be trended every 4 to 6 hours to document the status of the bleed
- Order a comprehensive metabolic panel to evaluate the following: elevated blood urea nitrogen, which indicates reabsorption of red blood cells; elevated creatinine, which indicates poor renal perfusion; liver function tests, which could reveal liver disease that is exacerbating bleeding
- International normalized ratio, especially if patient is taking warfarin
- Partial thromboplastin time, especially if the patient is on heparin
- Type and screen/cross in anticipation of the need for blood products
- Stool studies, including white blood cell count, gram stain, culture, and pathogen-specific testing to identify infectious etiologies

IMAGING STUDIES

- Computed tomography (CT) angiography can potentially identify the location of the bleed as well as abnormal vasculature.
- Perform a tagged red blood cell scan if source is not identified on CT angiography.
- CT scan of the abdomen and pelvis may identify malignancy as the source of bleeding.
- If free air is suspected from perforation, an abdominal or chest plain film should be ordered immediately. An abdominal plain film can also identify radiopaque foreign bodies.
- Abdominal ultrasound if intussusception is suspected.
- Meckel (technetium-99) scan if Meckel diverticulum is suspected.

TREATMENT

Begin crystalloid bolus to maintain a systolic blood pressure of at least 100 mm Hg. Transfuse for hemoglobin and hematocrit of 7 and 21, respectively, or less. If the patient has coronary artery disease or multiple medical comorbidities and is older than 65 yr, the goal hemoglobin and hematocrit are 8 and 24, respectively. Platelets should be maintained above 50,000 mm and international normalized ratio 1.5 or less.

NONPHARMACOLOGIC THERAPY

- Colonoscopy defines the colonic anatomy, can identify the source of bleeding, and allows for potential therapy.
- Endoscopy can be performed if the source of the bleed is suspected to be proximal to the ligament of Treitz.
- Anoscopy can be performed for bleeding internal hemorrhoids or other anorectal disorders.
- Balloon tamponade of esophageal or anorectal bleeds.
- Perform surgery if the source of the bleed cannot be otherwise identified, for aortoenteric fistula, or if air enema for intussusception is unsuccessful.
- Interventional radiology for embolization.
- Ablation.

ACUTE GENERAL Rx

Proton pump inhibitor, histamine 2 blocker if suspecting UGI blood with rapid transit

CHRONIC Rx

Avoid NSAIDs and alcohol. Treat the underlying cause of the bleed, e.g., coagulopathy, portal hypertension, etc. Most patients are prescribed

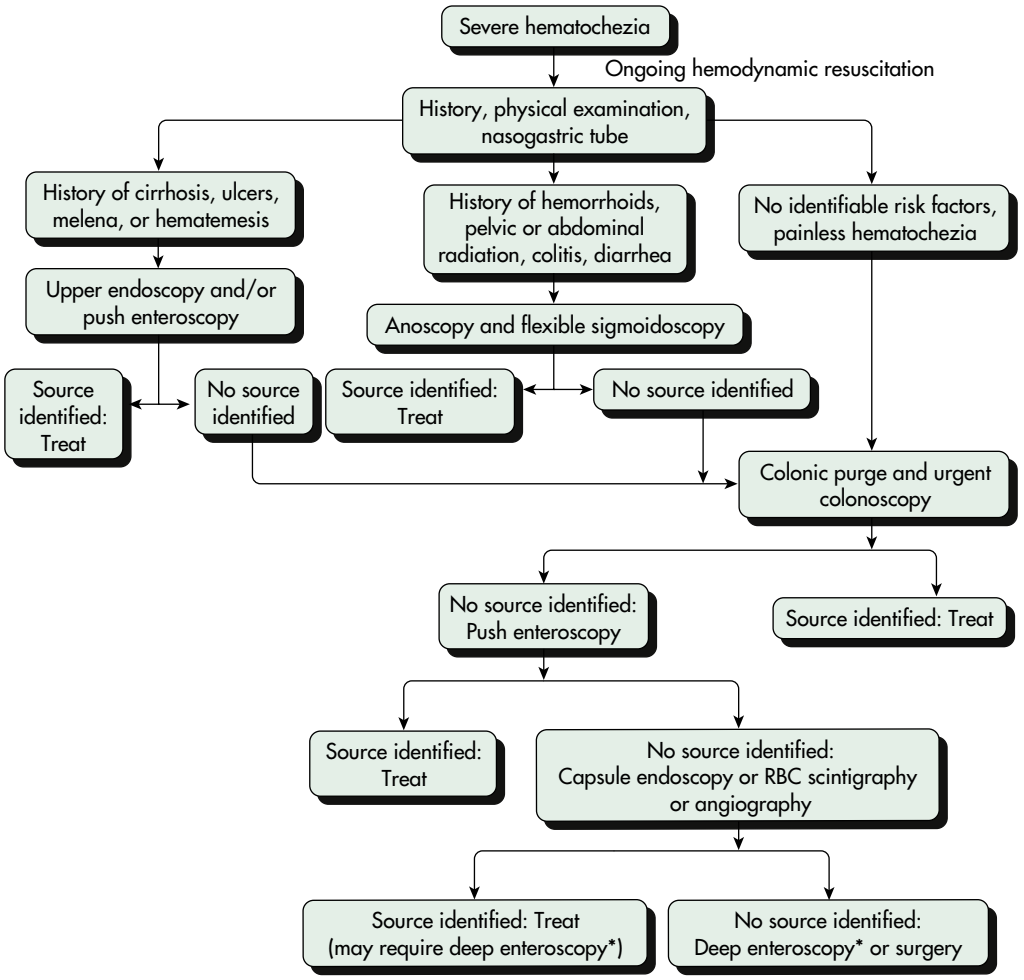

FIG. 1 Algorithm for the management of severe hematochezia modified according to patient's history. *Deep enteroscopy includes double-balloon enteroscopy, single-balloon enteroscopy, and spiral enteroscopy. *RBC,* Red blood cell. (From Feldman M et al: *Sleisenger and Fortran's gastrointestinal liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

daily proton pump inhibitors. Fiber, stool softeners, and analgesic creams may alleviate development and/or symptoms of hemorrhoids.

DISPOSITION

Lower GI bleeding will resolve spontaneously in 80% to 85% of patients. Therefore, if the patient is hemodynamically stable without symptomatic anemia or brisk bleeding, he or she may follow up with his or her primary care physician or a gastroenterologist. However, patients with shock or other hemodynamic compromise, severe bleeding, or significant comorbidities should be admitted to the intensive care unit. These patients are at high risk for acute decompensation and as such require close monitoring and aggressive resuscitation; furthermore, they will require urgent diagnosis and intervention to stop the bleeding. Clinical factors predictive of severe colonic bleeding include aspirin use, at least two comorbid illnesses, pulse greater than 100 beats/minute, and systolic blood pressure <115 mm Hg. The overall mortality rate from colonic bleeding is 2.4% to 3.9%. Independent predictors of in-hospital mortality are age over 70 yr, intestinal ischemia, and two or more comorbidities.

REFERRAL

Patients should be referred to gastroenterology for follow-up.

BASIC INFORMATION

DEFINITION

Acute lymphoblastic leukemia (ALL) is a malignancy of precursor B or T lymphocytes (lymphoblasts) characterized by uncontrolled proliferation of malignant lymphocytic cells with replacement of normal bone marrow elements and bone marrow failure. Lymphoblastic lymphoma is diagnosed when the disease presents in extramedullary sites (most commonly as mediastinal mass in T-cell disease) *and* less than 25% of the bone marrow is involved.

SYNONYMS

Acute lymphocytic leukemia
Acute lymphoblastic leukemia
ALL

ICD-10CM CODES

C91.00	Acute lymphoblastic leukemia not having achieved remission
C91.01	Acute lymphoblastic leukemia, in remission
C91.02	Acute lymphoblastic leukemia, in relapse

EPIDEMIOLOGY & DEMOGRAPHICS

- ALL is primarily a disease of children (peak incidence occurring at 3 to 5 yr of age).
- Overall incidence is 4.5 cases per 100,000 persons per yr; 60% are under age 20. It is the most common malignancy of childhood. (SEER database accessed 11/26/15.)
- Incidence varies according to race and ethnic group: 14.8 cases per million for blacks, 35.6 cases per million for whites, and 40.9 cases per million for Hispanics.
- Male:female ratio is 55% to 45%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Findings consistent with bone marrow failure and peripheral cytopenias—pallor, bruising, petechiae
- Lymphadenopathy or hepatosplenomegaly
- Fever (disease related or infectious), bone pain, weakness, weight loss, mental status changes, and neurologic findings associated with central nervous system (CNS) involvement (if present)
- T-cell lymphoblastic lymphoma is usually associated with a mediastinal mass
- Table 1 summarizes the clinical presentation of acute lymphoblastic leukemia

ETIOLOGY

- Most cases are sporadic without established risk factors.
- Ionizing radiation exposure appears to be a risk factor.
- Down syndrome (trisomy 21) is associated with an approximately 3% risk of developing leukemia by age 30, predominantly ALL. ALL may be seen with other hereditary premalignancy syndromes (e.g., ataxia-telangiectasia)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Disorders associated with lymphocytosis (lymphocytes >5000/mcl):

- Adults: Chronic lymphocytic leukemia, mantle cell lymphoma, marginal zone lymphoma, hairy cell leukemia
- Adolescents/young adults: Infectious mononucleosis syndromes due to Epstein-Barr virus or cytomegalovirus, among others, may present with lymphocyte abnormalities with appearance suggestive of leukemic blasts
- Disorders associated with circulating blasts or blastlike cells such as acute myeloid leukemia, prolymphocytic leukemia, blastoid mantle cell lymphoma, and Burkitt lymphoma (mature B-cell leukemia/lymphoma)
- Lymphoblastic lymphoma
- Aplastic anemia; ALL may present without circulating leukemia cells and with only manifestations of bone marrow failure

WORKUP

- Identification of circulating abnormal cell population by flow cytometry. CD19 identifies most precursor B cells. Immature leukemic blasts should have *absence* of surface immunoglobulin and will usually express CD34 and stain positive for terminal deoxynucleotidyltransferase (TdT). Cytoplasmic CD3 and CD7 establish immature T-cell lineage in most cases. Aberrant myeloid markers (CD13, CD33) can be seen.
- Cytochemical stains are sometimes easier to perform and may be available sooner but are less specific. ALL blasts should be negative for myeloperoxidase and esterase stains.
- Bone marrow examination (Fig. E1).
- Genetic studies define important treatment categories, of which the most important is Philadelphia chromosome positive (Ph+) vs. Philadelphia chromosome negative (Ph–) disease, as these are treated differently. Ph status can be determined rapidly by polymerase chain reaction (PCR) or fluorescence *in situ* hybridization (FISH) and should be available within 24 to 48 hours of diagnosis. The WHO classification recognizes genetic variants of ALL as distinct syndromes (Table 2), and the clinical significance of common abnormalities is outlined in Table 3.
- Genetic profiling for "Ph-like" ALL (genetic profile similar to Ph+ disease, but no BCR/ABL abnormality) or IKZF1 (IKAROS) mutations may provide additional prognostic information, but may not be uniformly available. Ph-like ALL may respond to tyrosine kinase inhibitor therapy and may behave more like Ph+ ALL.
- Lumbar puncture is usually done at diagnosis, if practical, to assess for CNS involvement and to initiate CNS prophylactic therapy.

LABORATORY TESTS

- Complete blood count reveals normochromic, normocytic anemia, thrombocytopenia.
- Peripheral smear will usually reveal lymphoblasts, but in some cases only the marrow is involved.
- Initial blood work should also include assessment for basic organ function (creatinine, bilirubin), blood glucose (glucocorticoids are part of therapy), and spontaneous tumor lysis syndrome (K^+, Ca^{++}, $PO4^{++}$, uric acid).
- Coagulation studies (full disseminated intravascular coagulation [DIC] screen) prior to lumbar puncture.
- Studies appropriate to identifying and risk-stratifying leukemia as outlined previously.

IMAGING STUDIES

- Chest x-ray to evaluate fever and for the presence of mediastinal mass.
- CT for symptomatic complaints. Be cautious about contrast dye exposure in patients with evidence of spontaneous tumor lysis syndrome to avoid further renal injury.

TREATMENT

ACUTE GENERAL Rx

- Survival of children with ALL has improved from 10% to 90% in the last 40 yr and is a major success story of modern medical science and research. Adults have fared less

TABLE 1 Clinical Presentation of Acute Lymphoblastic Leukemia

Symptoms/ Signs	Etiology	Management
Fever	Disease or infection	Always conduct fever work up and provide broad antimicrobial coverage until infectious etiology is ruled out
Fatigue, pallor	Anemia (ALL infiltrating bone marrow)	Packed red blood cell transfusion (slow if anemia is severe, avoid in hyperleukocytosis)
Petechiae, bruising, bleeding	Thrombocytopenia (ALL infiltrating bone marrow)	Transfuse with platelets
Pain	Leukemia infiltrating bones/ joints, or expanding marrow cavity	Establish diagnosis and start chemotherapy
Respiratory distress/ superior vena cava syndrome	Mediastinal mass	Avoid sedation in presence of tracheal compression. Establish diagnosis as soon as possible and start chemotherapy

ALL, Acute lymphoblastic leukemia.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE 2 WHO Classification of Precursor Lymphoid Neoplasms

B-lymphoblastic leukemia/lymphoma, not otherwise specified
B-lymphoblastic leukemia/lymphoma with recurrent cytogenetic abnormalities:
- B-lymphoblastic leukemia/lymphoma with t(9;22)(q34;q11.2); *BCR-ABL1*
- B-lymphoblastic leukemia/lymphoma with t(v*;11q23) *MLL* rearranged.
- B-lymphoblastic leukemia/lymphoma with t(12;21)(p13;q22); *TEL-AML1 (ETV6-RUNX1)*
- B-lymphoblastic leukemia/lymphoma with hyperdiploidy
- B-lymphoblastic leukemia/lymphoma with hypodiploidy
- B-lymphoblastic leukemia/lymphoma with t(5;14)(q32;q32); IL3-IGH
- B-lymphoblastic leukemia/lymphoma with t(1;19)(q23;p13.3); EZA-PBX1 (TCF3-PBX-1)

T-lymphoblastic leukemia/lymphoma
Provisional entities:
- B-lymphoblastic leukemia/lymphoma BCR/ABL1 like
- B lymphoblastic leukemia/lymphoma with iAMP21

Early T-cell precursor lymphoblastic leukemia/lymphoma

*v**, Variable gene partners; *WHO,* World Health Organization.

TABLE 3 More Common Recurrent Cytogenetic Abnormalities in B-Lymphoblastic Leukemia/Lymphoma

Abnormality	Clinical Relevance
t(9;22)(q34;q11.2); *BCR-ABL1*	Incidence approximately 3% in children, 25% in adults, rising with age; requires therapy with tyrosine kinase inhibitors.
t(v*;11q23) *MLL* rearranged	Most common variant is t(4;11); often presents with very high WBC; confers worse prognosis; rare in adults; common in infant leukemia.
t(12;21)(p13;q22); *TEL-AML1*	Common in children (20%-30%); rare in adults; confers improved prognosis.
Hyperdiploidy	Seen in about 25% of children, less in adults; confers favorable prognosis.
Hypodiploidy	Uncommon; confers worse prognosis.
t(5;14)(q32;q32); *IL3-IGH*	Rare; commonly associated with eosinophilia; T-cell disease, ? neutral prognostically
t(1;19)(q23;p13.3); *TCF3-PBX1*	Incidence approximately 5%; intermediate/favorable in children, intermediate/poor in adults.

*v**, Variable gene partners.
Many of these disorders also have distinct immunophenotypes by flow cytometry. Additional molecular abnormalities of recently defined relevance include mutations of *IKZF1,* which encodes a lymphoid transcription factor IKAROS, is associated with high relapse rates and gene expression profile similar to *BCR-ABL1* translocated disease. Gene expression profiling has identified a subgroup of "Philadelphia chromosome-like" acute lymphoblastic leukemia (ALL) with a gene expression similar to *BCR-ABL1* translocation associated disease, which confers worse prognosis, but which may identify new opportunities for targeted therapies.

well, but cure rates have also improved to about 60% to 70% in standard-risk patients in recent trials. Adults in particular have benefited from tyrosine kinase inhibitor therapy for Ph+ ALL, since this disease is more common in adults and may represent 50% or more of disease in patients over 50.

- **Hyperleukocytic leukemia** (WBC >100,000/mcl) is uncommon in ALL and lymphocyte counts of 100,000 may be well tolerated. Prednisone and vincristine usually offer rapid cytoreduction and leukapheresis is rarely (but sometimes) required.
- **Tumor lysis syndrome** is common in ALL and was seen in 23% of patients in one large series. It is sometimes spontaneous—i.e., present before therapy is given—and is a potential cause of early death. Tumor lysis syndrome is caused by release of intracellular potassium, phosphate, and nucleic acids. The nucleic acids adenosine and guanosine are eventually metabolized to uric acid. Elevated potassium may cause cardiac dysrhythmia and death. Elevated uric acid may cause renal failure through renal urate crystal deposition and possibly other mechanisms. Elevated phosphates cause renal calcium phosphate deposition and kidney injury while also lowering serum calcium, which can cause cardiac dysrhythmia and spasms. Therapy is directed mainly at maintaining renal function through vigorous hydration (3 liters normal saline per day if practical, alkalinization not recommended); "forced diuresis" if necessary to maintain urine output at 2 ml/kg/h; and dialysis if necessary to control K^+, phosphates, or fluid balance. Allopurinol, up to 800 mg/day for adults, 300 to 450 mg/m2/day for children, is given routinely. Rasburicase is a recombinant urate oxidase that rapidly lowers uric acid levels. The dose is 0.2 mg/kg, and one dose is usually enough. Rasburicase should be avoided in patients with G6PD deficiency. Phosphate binders are of uncertain value but are usually given. Asymptomatic hypocalcemia is not treated to avoid increasing calcium phosphate deposition. Definitions of laboratory and clinical tumor lysis and defined risk categories are outlined in Table 4.
- Numerous protocols have been used for Ph-ALL, and the specific protocol is likely to be determined by institution/physician familiarity and access to clinical trials, among other factors.
- In the 1990s and early 2000s, it was noted that adolescents and young adult (AYA) patients had better outcomes on pediatric trials than on adult trials. Consequently, this group (currently defined as ages 15 to 39) is now often (especially younger AYAs) treated on pediatric protocols by pediatric services or on adult "pediatric inspired" protocols.
- Therapy for Ph-negative ALL generally has four components:
  1. Induction therapy, typically with corticosteroids, cyclophosphamide (some regimens), vincristine, an anthracycline (doxorubicin or daunorubicin usually), and asparaginase. The CD20 directed antibody rituximab has shown benefit in patients with greater than 20% CD20 expression on their blast cells.
  2. Consolidation therapy is high-dose chemotherapy aimed at preventing relapse after remission and commonly consists of cytarabine and methotrexate in combination with other agents.
  3. Maintenance therapy is low-intensity outpatient therapy that is continued for 2 to 3 yr after completion of consolidation. Prednisone, monthly vincristine, methotrexate, and oral 6-mercaptopurine (POMP regimen) are commonly used.
  4. CNS prophylaxis is universal and is usually done with intrathecal therapy (methotrexate alone or in combination with cytarabine and hydrocortisone) administered by lumbar puncture or an Ommaya reservoir. Due to increased toxicity, cranial radiotherapy is reserved for patients with high-risk features, such as active CNS disease at diagnosis.
- Allogeneic bone marrow transplant in first remission of ALL is controversial because of improving results with current nontransplant therapies. It is usually recommended for patients in whom the likelihood of cure is considered less than 50% to 60% with chemotherapy alone, depending on age and donor availability. Autologous bone marrow transplant is rarely used in Ph-ALL. In 2008, the final results of the MRC/UKALL XII/ECOG E2993 study were published. This study evaluated the relative safety and efficacy of chemotherapy, and autologous and allogeneic transplant after first CR in Ph− patients. This was a randomized trial of 1826 patients with newly diagnosed ALL. Patients who had a matched related donor were offered an allogeneic transplant. Patients without a donor were further randomized to an autologous transplant or chemotherapy and maintenance. The key conclusions of this study were:
  1. Allogeneic transplant in first complete remission is associated with lower relapse rates versus autologous transplant or chemotherapy/maintenance therapy alone in Ph− patients.
  2. Allogeneic transplant in first complete remission improved overall survival in standard risk patients. There was a lower risk of relapse in both standard and high-risk patients. There was high treatment-related mortality in high-risk older

TABLE 4 Tumor Lysis Syndrome

Laboratory Tumor Lysis Syndrome[a]
Uric acid: ≥8 mg/dl or 476 μmol/L
Potassium: ≥6.0 mmol/L
Phosphorus: ≥4.5 mg/dl or 1.5 mmol/L (adults), ≥6.5 mg/dl or 2.1 mmol (children)
- Calcium: Corrected[b] Ca^{++} <7.0 mg/dl or 1.75 mmol/L or ionized Ca^{++} <1.12 mg/dl or 0.3 mmol/L, or 25% increase from baseline uric acid, potassium, phosphorus; 25% decrease for calcium.

Clinical Tumor Lysis Syndrome
Acute kidney injury
- Rise in serum creatinine ≥0.3 mg/dl (26.5 μmol/L).
- Any creatinine >1.5 age-appropriate upper limit normal if no baseline available.
- Oliguria defined as urine output <0.5 ml/kg/hr for 6 hours.

Cardiac arrhythmia
Seizure
Symptomatic hypocalcemia (e.g., neuromuscular irritability such as tetany)

[a]Laboratory tumor lysis syndrome present if two or more abnormalities are present within 3 days before or 7 days after therapy.
[b]Corrected calcium is measured calcium (mg/dl) + 0.8 × (4 – measured albumin g/dl).

patients. The increased mortality offsets the benefit of lower relapse risk for the patient group.
- The findings did not support autologous transplant as replacement therapy in any ALL group.
- Risk factors for treatment failure in recent protocols are outlined in Table 5. Prognostic factors in ALL are summarized in Tables 6 and 7.
- Therapy of Ph+ ALL consists of a tyrosine kinase inhibitor—imatinib, dasatinib, nilotinib, ponatinib have been used—with chemotherapy.
  1. 2-yr survival rates are reported at 50% to 65%, with various regimens.
  2. Low-intensity induction chemotherapy with dasatinib and prednisone or imatinib, vincristine, and prednisone have resulted in remission rates of 100% and 98% and may allow for less toxicity and hospitalization at diagnosis.
  3. Allogeneic bone marrow transplant is commonly used as consolidative therapy if available but has become more controversial. Maintenance therapy with tyrosine kinase inhibitor is usually given after BMT or non-BMT therapy.
- Therapy of relapsed disease:
  1. Allogeneic bone marrow transplant is offered for relapsed disease, but relapse after BMT is common, and long-term cure rates have been low at about 20%.
  2. In 2017, the FDA approved three new therapies for relapsed ALL: Chimeric antigen receptor T-cell (CAR-T) therapy, a form of targeted immunotherapy, yielded a remission rate of 90% in pediatric and young adult (under age 26 yr) patients with relapsed B-cell ALL. Chimeric antigen T-cells are created by harvesting the patient's T cells, then transfecting them with lentivirus vector that inserts DNA expressing an anti-CD19 domain (the target antigen on B cells) coupled to a T-cell receptor. The T cells expressing the chimeric anti-CD19/T-cell receptor specifically target CD19-expressing B cells. The CAR-T cell population is then expanded ex vivo and reinfused to the patient. About 70% of remissions were durable at 6 months. The main side effect is cytokine release syndrome (CRS) associated with "vascular leak," hypotension, respiratory and renal insufficiency, and coagulopathy. CRS is treated with tocilizumab and anti-IL6 receptor blocking antibody. CAR-T cells for ALL have been given the generic designation tisagenlecleucel (trade name Kymriah). It currently costs $475,000 and is available at centers certified for its use.
  3. Blinatumomab is a bispecific antibody that binds CD19 and CD3, redirecting T cells to leukemia cells. It was FDA-approved for relapsed ALL, including Ph+ ALL, in adults and children. Blinatumomab is administered as a continuous infusion for 4 wk (9 μg/day wk 1, 28 μg/day thereafter), with maintenance therapy for 4 wk every 12 wk. In a large phase III trial, the remission rate was 44% (vs. 25% with chemotherapy), a small number durable. In a smaller phase II trial for Ph+ ALL, the remission rate was 36%. A small number of blinatumomab responses have been durable. Blinatumomab can also be associated with cytokine release syndrome.
- Inotuzumab ozogamicin (IO) is an antibody drug conjugate, in which chemotherapeutic agent calicheamicin is bound to an anti-CD22 antibody. In a large phase III trial, the remission rate was 81% vs. 33% for standard chemotherapy, with a median duration of 4.6 mo. Approximately 40% of IO patients were successfully bridged to transplant vs. 10% with chemotherapy. A small number of responses were durable.
- Survivorship:
  1. Survivors of childhood and adult ALL are increasingly being seen in primary care practices; as of 2006 there were estimated >50,000 survivors, likely increasing by about 2000+ per yr.
  2. Long-term complications of ALL therapy include secondary malignancy from chemotherapy (usually in first 5 to 10 yr) or from radiation (if given, no plateau in risk, congestive heart failure from anthracycline therapy (often manifesting 20 to 30 yr after treatment), osteopenia and avascular necrosis from glucocorticoid therapy, obesity, and neurocognitive defects. Key recommendations include the following:
     a. Echocardiography every 3 to 5 yr for asymptomatic congestive heart failure, more often if anthracycline exposure was >250 to 300 mg/m^2, since asymptomatic congestive heart failure may warrant therapy. This may show up decades after therapy.
     b. Screening for malignancy and endocrinopathies in pertinent radiation fields.
     c. Attention to the increased risk of obesity and metabolic derangement in survivors.
     d. Recent reviews (see references) summarizing current recommendations and guidelines are accessible online (www.survivorshipguidelines.org/pdf/LTFUGuidelines_40.pdf, http://www.sign.ac.uk/pdf/sign132.pdf).

AUTHOR: **Todd F. Roberts, MD, FRCP(C)**

TABLE 6 Prognostic Factors in Acute Lymphoblastic Leukemia

Factor	Prognosis	Clinical Application
Age		
<1 yr	MLL+ (70%-80% infants) poor outcome; MLL– same outcome as older children	MLL–do well on standard ALL therapy Potential role for FLT3 inhibitors, proteasome inhibitors, histone deacetylase inhibitors, and hypomethylating agents for MLL+
1-9 yr	Lower (standard) risk	ALL biology may change risk
>9 yr	Higher risk	ALL biology may change risk
WBC		
$<50 \times 10^9$/L	Lower (standard) risk	ALL biology may change risk
$\geq 50 \times 10^9$/L	Higher risk	ALL biology may change risk
CNS		
CNS3	Higher risk of CNS and bone marrow relapse	Therapy intensification
CNS2 Traumatic lumbar puncture with blasts	Higher risk of CNS relapse	CNS directed therapy intensification
Testicular	Higher risk	Therapy intensification
Immunophenotype		
T cell	Higher risk	Poor outcome abolished with current therapy
pre-B (cIgM+)	Standard risk	Poor outcome abolished with current therapy
Early pre-B	Standard risk	Genetics may change risk
Early T-cell precursor	Adverse prognosis	Ongoing studies exploring targeted therapies
Ploidy		
>50 (DI >1.16)	Low risk	Good response to antimetabolites
<44	Higher risk	Therapy intensification
Genetic Alterations		
t(9;22)/*BCR-ABL1*	Higher risk	ABL TKI
t(4;11)/*MLL-AF4*	Higher risk	Potential role for FLT3 inhibitors, proteasome inhibitors, histone deacetylase inhibitors, and hypomethylating agents
t(1;19)/*E2A-PBX1*	Higher risk of CNS relapse	Improved outcome with current therapy
t(12;21)/*ETV6-RUNX1*	Low risk	
IKZF1	Poor prognosis. Present in 80% Ph+ and also in Ph-like ALL	Potential role for tyrosine kinase, JAK inhibitors
NUP214-ABL1	High risk	Potential benefits from TKI
CRLF2	In half of Ph-like cases, associated with Hispanic/Latino, poor outcome	Potential role for JAK inhibitors
CREBBP	Associated with drug resistance and relapse	Potential benefit from histone deacetylase inhibitors
MRD		
Day 15 <0.01%	Excellent outcome	No benefit from 2nd delayed intensification
Slow early responders	Higher MRD = higher risk of relapse	Benefit from augmented delayed intensification
End of induction >1%	Dismal prognosis	Transplantation in first CR
4 months after diagnosis >0.01%	Dismal outcome	Transplantation in first CR

ALL, Acute lymphoblastic leukemia; *CNS,* central nervous system; *CR,* complete remission; *DI,* deoxyribonucleic acid index; *JAK,* Janus kinase; *MLL,* mixed-lineage leukemia; *MRD,* minimal residual disease; *TKI,* tyrosine kinase inhibitor; *WBC,* white blood cell.

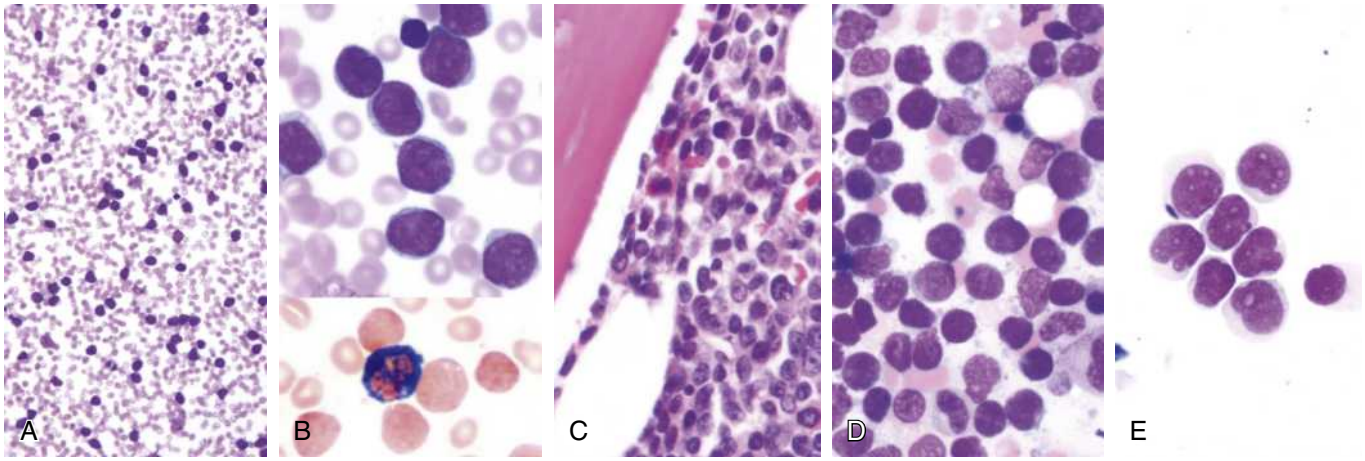

FIG. E1 Acute lymphoblastic leukemia: Peripheral blood, bone marrow biopsy and aspirate, and cerebral spinal fluid. The illustration is from a 37-yr-old male who presented with a white blood count of 170,000/L and more than 90% blasts with lymphoid morphology (**A** and **B,** *top*). An initial myeloperoxidase reaction (**B,** *bottom*) showed the blasts to be negative (positive cell is a segmented neutrophil that serves as an internal control). The bone marrow was packed with blasts as seen on the biopsy and aspirated material **(C** and **D)**. The blasts were immunophenotyped by flow cytometry and were shown to be precursor-B lymphoblasts with the following phenotype: CD34+, HLA–DR+, TdT+, CD19+, CDI0+, cyCD79A+, cylgM–, and slg–. Cytogenetic studies illustrated the t(9;22), and molecular analysis revealed the p190 *BCR/ABL*. A spinal tap showed a WBC count of 120/L with an RBC count of 37/L. The differential showed 80% blasts. The morphology of the blasts on the cytospin of the cerebrospinal fluid **(E)** is somewhat altered by the preparation. Note the absence of significant red blood cells in the specimen. Given the high number of blasts in the peripheral blood, a more traumatic tap would have made it difficult to distinguish between central nervous system disease and contamination of the cerebrospinal fluid specimen by blood. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 5, Philadelphia, 2009, Churchill Livingstone.)

BASIC INFORMATION

DEFINITION

Acute mesenteric ischemia (AMI) is the sudden onset of intestinal hypoperfusion to all or part of the small bowel caused by emboli, arterial or venous thrombosis, or vasoconstriction from low-flow states, which ultimately leads to ischemia and secondary inflammatory changes.

SYNONYMS

AMI
Mesenteric ischemia, acute

ICD-10CM CODE
K55.0 Acute vascular disorders of intestine

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Accounts for 0.09% to 0.2% of all acute admissions to emergency departments.
- Mortality ranges between 50% and 80%.
- The incidence appears to be increasing. Factors for this include increased awareness among clinicians, improved diagnostic modalities, the aging of the population, and improved intensive care leading to longer survival of sicker patients.

PREDOMINANT SEX AND AGE:

- AMI caused by arterial embolism or thrombosis occurs more frequently in the elderly.
- AMI due to mesenteric venous thrombosis often presents in younger age groups.

GENETICS: No specific genetic predisposition but may be related to underlying factors such as cardiac disease, atherosclerosis, and hypercoagulable states.

RISK FACTORS:

- Advanced age, atherosclerosis, low cardiac output (especially atrial fibrillation), severe cardiac valvular disease, intraabdominal malignancy.
- In the subgroup of cases caused by venous thrombosis, risk factors include hypercoagulable states, portal hypertension, abdominal infection, blunt trauma, pancreatitis, and portal malignancy.
- Additional risk factors for AMI caused by non-occlusive mesenteric ischemia include recent cardiac or aortic surgery, dialysis, hypovolemia, and vasoconstrictive medications (including illicit drugs such as cocaine).
- Table 1 summarizes risk factors for ischemic bowel disease.
- AMI may also occur rarely in patients with no identifiable risk factors.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The classic presentation is rapid onset of severe periumbilical pain "out of proportion to physical examination findings."
- Approximately one third of patients present with the triad of abdominal pain, fever, and hemoccult-positive stools. Nausea and vomiting are commonly associated.
- Generally patients with mesenteric venous thrombosis tend to present with less abrupt onset of abdominal pain than those with acute arterial occlusion.
- Initial abdominal examination may be normal, with no rebound or guarding, or may include minimal distention or stool positive for occult blood. An epigastric bruit may be present in some patients.
- Later in the disease course the patient may present with septic shock, gross abdominal distention, absence of bowel sounds, and peritoneal signs. In the elderly, mental status changes may occur.
- If the physical examination demonstrates signs of peritonitis, there is likely irreversible intestinal ischemia with bowel necrosis.

ETIOLOGY

Conventionally, AMI is stratified into four groups by etiology: arterial embolism, arterial thrombosis, venous thrombosis, and nonocclusive mesenteric ischemia (NOMI). The pathophysiology behind these different etiologies is summarized in Table 2. Causes and approximate frequencies of acute mesenteric ischemia are summarized in Table 3. The pathophysiologic mechanisms that cause AMI include:

TABLE 1 Risk Factors for Ischemic Bowel Diseases*

TABLE 2 Pathophysiology of the Four Different Causes of Acute Mesenteric Ischemia (AMI)

Cause	Pathophysiology
Embolism	• Often in patients with atrial fibrillation • Emboli lodge 3-10 cm distal to origin of SMA, often past branching of middle colic artery • Proximal midjejunum is spared
Thrombosis	• Typically these patients have a history of symptomatic stenosis of mesenteric arteries • Any clinical scenario that leads to low flow or hypotension can result in acute-on-chronic arterial thrombosis • Affects the orifice of the SMA • Flush occlusion of the SMA and the entire middle gut is involved during the initial presentation
Nonocclusive	• Low flow state resulting from any type of shock or the use of vasoconstrictors • The entire bowel may be involved
Mesenteric venous thrombosis	• Thrombosis of the veins draining the intestines; SMV, IMV, splenic and portal veins among hypercoagulable patients with cancer or hypercoagulable state • Decreased venous outflow, bowel edema, distension, and decreased mesenteric perfusion

IMV, Inferior mesenteric vein; *SMA,* superior mesenteric artery.
Modified from Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

TABLE 3 Causes and Approximate Frequencies of Acute Mesenteric Ischemia

Cause	Frequency (%)
SMA thrombosis	54-68
SMA embolus	26-32
Nonocclusive mesenteric ischemia	10
Mesenteric venous thrombosis	5
Focal segmental ischemia of the small intestine	5

SMA, Superior mesenteric artery.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

- Mesenteric arterial embolism (40% to 50% of cases of AMI) typically arises from a cardiac source: left atrium associated with cardiac dysrhythmias such as atrial fibrillation, left ventricle with global myocardial dysfunction associated with poor ejection fraction, or cardiac valves due to endocarditis. The superior mesenteric artery (SMA) is most commonly affected because of its relatively large diameter and low takeoff angle from the aorta.
- Mesenteric arterial thrombosis (20% to 35% of cases of AMI) is often seen in patients with prior progressive atherosclerotic stenosis, with superimposed abdominal trauma or infection. Many of these patients have a history consistent with chronic mesenteric ischemia (CMI), including postprandial pain, weight loss, or "food fear."
- Nonocclusive mesenteric ischemia (20% of cases of AMI) is usually a consequence of SMA vasoconstriction associated with low splanchnic blood flow as seen with hypotension, hypovolemia, vasoconstricting drugs, and hemodialysis.
- Mesenteric venous thrombosis (less than 10% of cases of AMI) may occur in the setting of hypercoagulable states (acquired or inherited), blunt trauma, abdominal infection, portal hypertension, pancreatitis, and portal malignancy. In these situations, the consequences of bowel edema and increased vascular resistance secondary to venous thrombosis result in reduced arterial blood flow, leading to bowel ischemia.
- Dissection or inflammation of the mesenteric artery accounts for less than 5% of cases of AMI.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Initially include other causes of acute-onset abdominal pain, including perforated peptic ulcer, acute pancreatitis, and early appendicitis, as well as the varied causes of peritonitis.

WORKUP

- Early diagnosis is key, and the key to early diagnosis is a high level of clinical suspicion.
- Treatment success is related to the duration of symptoms before diagnosis. Consider early laparotomy for diagnosis in cases with a high index of suspicion when imaging is not readily available.

LABORATORY TESTS

- Classically, patients with AMI have leukocytosis, metabolic acidosis, elevated D-dimer, and elevated serum lactate; however, these laboratory test results are nonspecific, especially early in the course. Elevated lactic acid, leukocytosis, and elevated hematocrit from hemoconcentration can occur later in the course, often after progression to bowel necrosis has occurred, hence are not useful for early diagnosis.
- D-Dimer has been reported to be an independent risk factor of intestinal ischemia, reflecting ongoing clot formation and endogenous degradation via fibrinolysis. Normal D-dimer testing may help rule out AMI while elevated levels are nonspecific.
- When a hypercoagulable state is suspected, workup may include proteins C and S, antithrombin III, and factor V Leiden. This will likely not affect the diagnosis of AMI but may help guide long-term therapy.
- Amylase levels may be elevated in up to 50% of individuals with intestinal ischemia; phosphate levels may be elevated in up to 80% of affected individuals.

IMAGING STUDIES

- Contrast-enhanced computed tomography (CT) has replaced conventional angiography as the gold standard imaging modality in AMI. It is more readily available and has similar sensitivity to angiography, the prior gold standard test. Computed tomographic angiography (CTA) has 95% to 100% accuracy for the diagnosis of visceral ischemic syndromes and is also useful in detecting potential sources of emboli and other pathologic processes.
- Plain CT findings are nonspecific and more often found late in the course. Portal venous gas or intramural gas may be seen after the development of gangrene (Fig. E1). In many cases, CT findings remain nonspecific even at advanced stages.
- Gadolinium-enhanced magnetic resonance imaging (MRI) can be used to detect proximal obstruction of the SMA and celiac axis, but it has less value in the evaluation of distal arterial occlusions and other intestinal findings in AMI. Magnetic resonance angiography (MRA) may be more useful in cases of mesenteric vein thrombosis causing AMI. It has also been found useful in monitoring the progress of patients with superior mesenteric venous thrombosis who are treated non-surgically. MRA, however, takes longer than CTA to perform and can overestimate the degree of stenosis.
- Plain radiographs are not useful in AMI; plain films are normal 25% of the time in early stages. Suggestive findings may include ileus (Fig. E2), bowel wall thickening, or intramural gas. Gas in the portal veins is a sign of extensive intestinal pneumatosis and implies that bowel necrosis has developed. Free air under the diaphragm may support early surgical intervention before further radiologic evaluation.
- Ultrasound is not recommended in AMI if CT is available. Doppler ultrasound evaluation of intestinal blood flow is time consuming and is often limited by the presence of air-filled loops of bowel.

Angiography may be considered if the diagnosis remains unclear after CT or MRI.

Rx TREATMENT

- The goal of treatment is to restore blood flow to ischemic bowel as rapidly as possible (Fig. E3) before the occurrence of infarction.
- Treatment varies depending on specific etiology.

ACUTE GENERAL Rx

- Initial management should include hemodynamic monitoring and support, including fluid resuscitation with crystalloid and blood products, correction of acidosis, pain control (using parenteral opioids), administration of broad-spectrum antibiotics, and gastric decompression by nasogastric tube.
- Vasopressors should be used with caution and only to avoid fluid overload and abdominal compartment syndrome. Dobutamine, low-dose dopamine, and milrinone to improve cardiac function have been shown to have less impact on mesenteric blood flow.
- In the absence of active bleeding, the use of systemic anticoagulation is usually indicated. The optimal timing of initiation is unclear.

NONPHARMACOLOGIC THERAPY

- Specific management will depend on patient status and most likely etiology of the ischemia. Signs of peritonitis mandate early laparotomy and resection of infarcted bowel.
- When workup is positive for major SMA embolus, embolectomy is considered standard treatment in the absence of peritoneal signs. Depending on the location and degree of occlusion of the embolus, surgical revascularization, intraarterial infusion of thrombolytics or vasodilators, or systemic anticoagulation may be considered.
- In cases of SMA thrombosis, emergency surgical revascularization is the treatment of choice. Stent placement may be a viable alternative.
- Management of NOMI is based on treatment of the underlying precipitating cause. Fluid resuscitation, optimization of cardiac output, and elimination of vasopressors remain important primary measures. Additional treatment may include systemic anticoagulation and the use of catheter-directed infusion of vasodilatory and antispasmodic agents, most commonly papaverine hydrochloride.
- In patients with mesenteric vein thrombosis, treatment depends on the presence or absence of peritoneal signs. Laparotomy and resection of infarcted bowel is indicated in more advanced cases. If there are no peritoneal signs, immediate anticoagulant therapy with heparin, and ultimately warfarin, may be adequate treatment.
- In general, percutaneous treatment with lytic therapy, balloon angioplasty, or stenting may be limited by the frequent presence of nonviable bowel, which would require laparotomy despite success with percutaneous treatment.
- A "second look" procedure is indicated in most patients, 24 to 48 hours after initial revascularization.

CHRONIC Rx

Patients should be followed up in an outpatient clinical setting at regular intervals.

- Patients who receive endovascular treatment should be managed with 3 to 6 months of clopidogrel; additionally, periodic surveillance for restenosis with duplex ultrasound or CTA is indicated.
- In the subgroup of patients with mesenteric venous thrombosis, prevention of further thrombosis is indicated. The optimal duration of anticoagulation is unclear.

DISPOSITION

- Prognosis is best in AMI due to mesenteric venous thrombosis and after surgical treatment for acute arterial embolism. It remains poor in cases of arterial thrombosis and nonocclusive ischemia.
- With delayed diagnosis, intestinal infarction—resulting in perforation or gangrenous bowel, sepsis, shock, and death—is typical.

REFERRAL

- Early surgical consultation should be considered. There should be no delay in patients with peritoneal signs.
- Surgery may also be warranted for diagnostic purposes.

PEARLS & CONSIDERATIONS

COMMENTS

- The diagnosis of AMI should be considered in any patient with acute onset of abdominal pain out of proportion to physical findings, particularly in at-risk patients.
- Early diagnosis, before intestinal infarction occurs, is critical and correlates with improved survival rates.
- The use of endovascular procedures for AMI is becoming more common and may be most appropriate for patients with ischemia that is not severe and for those who have severe coexisting conditions that place them at high risk for complications and death associated with open surgery.

PREVENTION

Prevention of underlying factors, most notably atherosclerotic disease (smoking cessation, management of hypertension, and use of statins) is indicated for primary prevention as well as prevention of recurrence.

Acute Myeloid Leukemia ALG PTG

BASIC INFORMATION

DEFINITION

Acute myeloid leukemia (AML) is a malignancy of hematopoietic progenitor cells that would normally give rise to mature granulocytes. Strictly speaking, AML is a subset of acute nonlymphocytic leukemia (ANLL), a designation that broadly distinguishes these diseases from the biologically distinct leukemias of lymphocytic origin. ANLL includes leukemias involving the spectrum of myeloid stem cells, including precursors of granulocytes, monocytes, erythrocytes, and megakaryocytes. Acute promyelocytic leukemia is a distinct leukemia syndrome that is part of the ANLL spectrum, but that has very different treatment implications. ANLL is characterized by maturation failure of myeloid progenitors, excessive numbers of immature progenitors ("blasts"), and various degrees of bone marrow failure (neutropenia, thrombocytopenia, anemia).

SYNONYMS

Acute nonlymphocytic leukemia (ANLL)
Acute myelogenous leukemia (AML)

ICD-10CM CODES

C92.60	Acute myeloid leukemia with 11q23-abnormality not having achieved remission
C92.61	Acute myeloid leukemia with 11q23-abnormality in remission
C92.62	Acute myeloid leukemia with 11q23-abnormality in relapse
C92.90	Myeloid leukemia, unspecified, not having achieved remission
C92.91	Myeloid leukemia, unspecified in remission
C92.92	Myeloid leukemia, unspecified in relapse
C92.A0	Acute myeloid leukemia with multilineage dysplasia, not having achieved remission
C92.A1	Acute myeloid leukemia with multilineage dysplasia, in remission
C92.A2	Acute myeloid leukemia with multilineage dysplasia, in relapse
C92.Z0	Other myeloid leukemia not having achieved remission
C92.Z1	Other myeloid leukemia, in remission
C92.Z2	Other myeloid leukemia, in relapse
C92.00	Acute myeloblastic leukemia, not having achieved remission
C92.01	Acute myeloblastic leukemia, in remission
C92.02	Acute myeloblastic leukemia, in relapse

EPIDEMIOLOGY & DEMOGRAPHICS

- AML incidence rises with age:
  1. Incidence 20 to 55 yr old: 1 to 3/100,000 persons/yr
  2. Incidence 65 to 80 yr old: 11 to 20/100,000 persons/yr
- Annual incidence is 4 cases/100,000 persons/yr
- Males slightly > females; European ancestry slightly > African ancestry

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Symptoms/exam findings:

- Complications of bone marrow failure:
  1. Thrombocytopenia-associated bleeding
  2. Fatigue and shortness of breath associated with anemia
  3. Infection associated with neutropenia
- Complications of leukocytosis (hyperleukocytic leukemia, WBC >100,000/mcl):
  1. Retinal hemorrhage with visual symptoms
  2. Headache and intracranial bleeding
  3. Respiratory symptoms from pulmonary involvement
- Systemic symptoms:
  1. Fatigue, fever (usually infectious, rarely tumor), bone pain (more common in ALL)
- Hemorrhagic complications of disseminated intravascular coagulation (DIC), especially with acute promyelocytic leukemia (APML)
- Physical exam will reflect consequences of cytopenias (bruising from thrombocytopenia, pallor from anemia). Enlarged lymph nodes and enlarged liver and spleen are rare. Exam is often normal
- Rarely disease will present as skin lesions (leukemia cutis) or mass lesions (granulocytic sarcoma)
- Gum hypertrophy and organ/skin involvement is more common in monocytic leukemia

ETIOLOGY

- Environmental/exposure related: Benzene (best documented), organic solvents (including gasoline), cigarette smoking (≥20 pack-yr 1.34 relative risk), obesity, best documented in women
- Hereditary disorders: Numerous, including Fanconi anemia, Bloom syndrome, Schwachman Diamond syndrome, Diamond Blackfan anemia, among others
- Therapy related:
  1. Alkylator (e.g., melphalan, busulfan, cisplatin) related: Typical latency 5 to 7 yr, associated with chromosome 5 and 7 abnormalities
  2. Topoisomerase II inhibitor (e.g. etoposide, doxorubicin): Typical latency 1 to 3 yr, associated with 11q23 (mixed lineage leukemia [MLL] gene) rearrangements
- Radiation exposures (therapeutic—generally low risk), occupational
- Antecedent hematologic disorders: Myelodysplasia, myeloproliferative disorders, aplastic anemia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Disorders that can present with circulating blasts or cells with blastlike appearance:
  1. Acute myeloid leukemia/acute lymphocytic leukemia
  2. Myelodysplasia (up to 20% circulating blasts, if ≥20% = AML)
  3. Primary myelofibrosis
  4. Chronic myeloid leukemia
  5. Blastoid variant of mantle cell lymphoma
  6. Prolymphocytic leukemia
  7. Blastic plasmacytoid dendritic cell neoplasm
  8. Atypical lymphocytes of Epstein-Barr and cytomegalovirus infection may have blastlike appearance

WORKUP

The diagnostic workup consists of a morphologic assessment, immunophenotyping by flow cytometry, assessment of karyotype, and a panel of gene mutations (Fig. 1).

LABORATORY TESTS

- Complete blood counts and blood smear evaluation. Note that morphologic evaluation of blasts may suggest myeloid or lymphoid origin, but flow cytometry or cytochemistries (often faster) are needed to confirm. Auer rods are seen in blasts of myeloid origin.
- LDH is commonly elevated. Other biochemistries to assess organ function (creatinine, liver enzymes) and spontaneous tumor lysis syndrome (uric acid, potassium, phosphate, calcium).
- Coagulation studies to assess DIC. DIC is always present in APML, but can be present in ***all*** forms of acute leukemia, especially acute monocytic leukemia.
- HLA typing for possible bone marrow transplant and platelet support.
- Cytochemical stains:
  1. Myeloperoxidase can be performed in minutes, + in myeloid origin leukemia.
  2. Alpha naphthyl acetate esterase ("nonspecific esterase") stains mainly monocytic cells.
- Flow cytometry on blood and/or bone marrow (see Table E1).
- Cytogenetic studies, ideally on bone marrow, but can be done on peripheral blood. Fluorescence in situ hybridization (FISH) is often used as an adjunct to conventional chromosome analysis.
- Next Generation Sequencing (NGS) by PCR to detect specific prognostic gene mutations
- Molecular studies to further stratify risk and prognosis, which may affect treatment choices (see Tables E2, 3, and 4). Directing this workup should be done with combined hematology and laboratory expertise and typically will consist of studies for fms-related tyrosine kinase gene (FLT3) mutations, nucleophosmin gene (NPM) mutations, and CCAAT/enhancer binding protein α gene (CEBPA) mutations. Wider molecular panels are increasingly common because of the increasing numbers of potential markers and the potential availability of targeted therapies for FLT3 mutated disease and those with isocitrate dehydrogenase mutations, among others. TP53 mutation, mutated RUNX1, and mutated ASXL1 have recently been added to the NCCN poor-risk category for AML in 2018. Table E5 summarizes common recurrent mutations in adult acute myeloid leukemia.

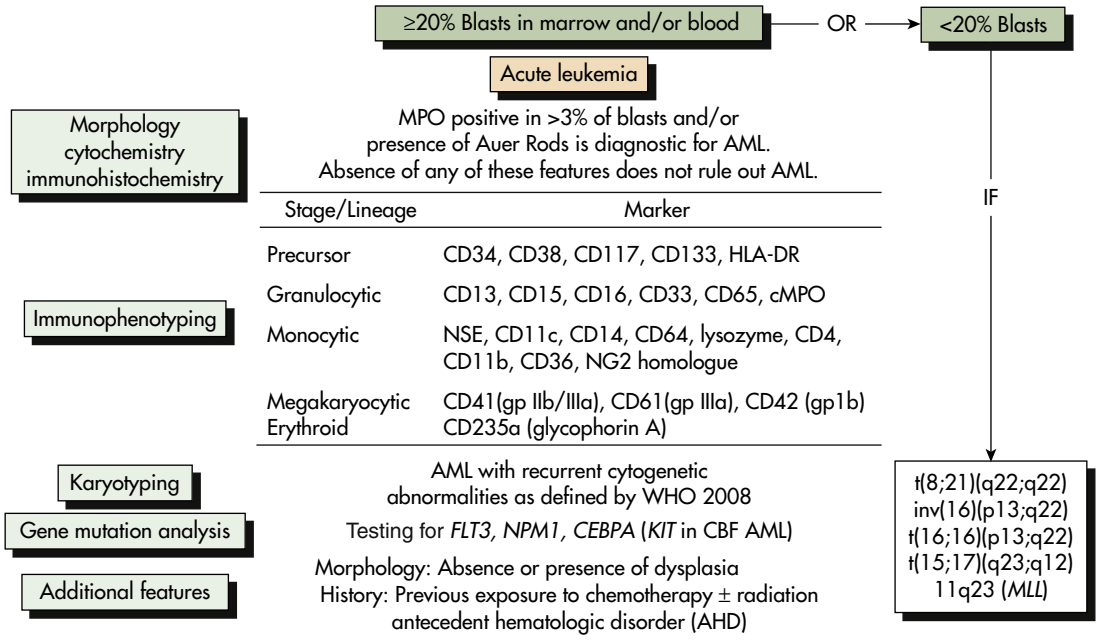

FIG. 1 Workup of acute myeloid leukemia. The diagnostic workup consists of a morphologic assessment, immunophenotyping by flow cytometry, assessment of the karyotype, and a panel of gene mutations. Whereas morphologic assessment by itself is often not sufficient to render a diagnosis, flow cytometry will confirm the lineage assignment (myeloid vs. lymphoid) and stage of differentiation in more than 95% of cases. In the remainder, either no lineage-specific antigens are expressed (acute undifferentiated leukemia) or antigens of more than one lineage are present (mixed-phenotype acute leukemia). In the latter scenario, antigens of several lineages can be found on one (biphenotypic) or separate populations of blasts (bilineal). Karyotyping and gene mutation analysis may add diagnostic information in morphologically ambiguous situations but is otherwise of more interest in determining prognosis. Additional information (exposure to previous chemotherapy and/or radiation therapy, history of an antecedent hematologic disorder, dysplasia) forms the basis for the 2008 revision of the WHO classification of AML. *AHD,* Antecedent hematologic disorder; *AML,* acute myeloid leukemia; *ANLL,* acute nonlymphocytic leukemia; *CBF,* core-binding factor; *MPO,* myeloperoxidase; *WHO,* World Health Organization. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

TABLE 3 European LeukemiaNet AML Risk Classification

Genetic Group	Subsets
Favorable	t(8;21)(q22;q22); *RUNX1-RUNX1T1*
	inv(16)(p13.1q22) or t(16;16)(p13.1;q22); *CBFB-MYH11*
	Mutated *NPM1* without *FLT3*-ITD (normal karyotype)
	Mutated *CEBPA* (normal karyotype)
Intermediate-I[a]	Mutated *NPM1* and *FLT3*-ITD (normal karyotype)
	Wild-type *NPM1* and *FLT3*-ITD (normal karyotype)
	Wild-type *NPM1* without *FLT3*-ITD (normal karyotype)
Intermediate-II	t(9;11)(p22;q23); *MLLT3-MLL*
	Cytogenetic abnormalities not classified as favorable or adverse[b]
Adverse	inv(3)(q21q26.2) or t(3;3)(q21;q26.2); *RPN1-EVI1*
	t(6;9)(p23;q34); *DEK-NUP214*
	t(v;11)(v;q23); *MLL* rearranged
	–5 or del(5q); –7; abnl(17p); complex karyotype[c]

[a]Includes all AMLs with normal karyotype except for those included in the favorable subgroup; most of these cases are associated with poor prognosis.
[b]For most abnormalities, adequate numbers have not been studied to draw firm conclusions regarding their prognostic significance.
[c]Three or more chromosome abnormalities in the absence of one of the WHO designated recurring translocations or inversions, that is, t(15;17), t(8;21), inv(16) or t(16;16), t(9;11), t(v;11)(v;q23), t(6;9), inv(3), or t(3;3).
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

- Formal diagnosis of acute nonlymphocytic leukemia is established if the marrow or peripheral blood blast percentage is ≥20%, unless t(8;21), inv(16), t(16;16) or t(15;17) are present, in which case the percentage of blasts may be lower.

1. Myeloperoxidase (MPO) staining of 3% of blasts establishes myeloid lineage, but MPO may be negative in some AML cases diagnosed by flow cytometry.
2. Specific criteria exist for diagnosing other forms of ANLL, mainly to distinguish it from myelodysplasia. The WHO AML classification is outlined in Table 6.
3. Bone marrow findings are described in Fig. E2.

IMAGING STUDIES

- Imaging studies are typically directed to evaluating specific complaints.
- Echocardiogram or multigated acquisition scan is usually performed to verify that cardiac function is adequate to tolerate anthracycline (usually daunorubicin) therapy, with left ventricular ejection fraction (LVEF) of >50% typically considered acceptable.

Rx TREATMENT

ACUTE GENERAL Rx

- The general approach to AML is summarized in Fig. 3. Therapy of AML typically has three components:

1. Immediate therapy to correct metabolic, infectious, or hyperleukocytic emergencies (if needed). Therapy for AML is always urgent but not always an emergency. However, treatment for APML should be considered a medical emergency to prevent catastrophic bleeding.
2. Induction therapy, which is therapy of active disease intended to obtain remis-

TABLE 4 Allogeneic Transplantation Guidelines for Adult Acute Myeloid Leukemia Based on Commonly Assessed Cytogenetic and Molecular Markers

AML Category	Prognostic Impact	Allogeneic Transplantation	Notes
AML-CR1: Younger Adults			
Good-risk disease			
APL	Favorable	No	APL is treatable by chemotherapy.
CBF-AML *without mKIT*	Favorable	No	t(8;21) AML with high WBC count at diagnosis may have worse prognosis.
CBF-AML *with mKIT*	Intermediate	Possible: MRD, MUD Uncertain: MMUD, UCB, haplo	
Intermediate-Risk Disease			
CN-AML *with CEBPA*	Favorable	No	Benefit likely restricted to *DM-CEBPA*
CN-AML *with mutant NPM1 but not FLT-3-ITD*	Favorable	Possible: MRD	Emerging data suggests allogeneic HSCT benefit for this category, with reduced relapse and improved DFS in patients >40 yr.
CN-AML *with FLT-3-ITD*	Unfavorable[a]	Yes: MRD, MUD Possible[b]: MMUD, UCB, haplo	Unfavorable risk may be restricted to AML *with FLT-3-ITD allelic ratio >0.51*
Other intermediate-risk disease	Intermediate or Unfavorable	Yes: MRD Likely acceptable[a]: MUD Possible[b]: MMUD, UCB, haplo	Likely considerable underlying clinical heterogeneity. Molecular risk profiling may further delineate risk in this category.
Poor-Risk Disease			
Monosomal karyotype *absent*	Unfavorable	Yes: MRD, MUD Likely acceptable[b]: MMUD, UCB, haplo	
Monosomal karyotype *present*	Very unfavorable	Yes: MRD, MUD Acceptable[b]: MMUD, UCB, haplo	
Abnormal 17(p)	Very unfavorable	Yes: MRD, MUD Acceptable[b]: MMUD, UCB, haplo	
AML-CR1: Older adults	Unfavorable	Yes: MRD, MUD Likely acceptable[b]: MMUD, UCB, haplo	
AML-CR1: t-AML, AML/MDS	Unfavorable	Yes: MRD, MUD Acceptable[b]: MMUD, UCB, haplo	Molecular risk profiling may supersede clinical classification of secondary AML, especially in older patients.
AML-CR2	Very unfavorable	Yes: MRD, MUD Acceptable[b]: MMUD, UCB, haplo	
AML not in remission	Very unfavorable	Yes: MRD, MUD Uncertain: MMUD, UCB, haplo	For selected patients: Good performance status, little comorbidity, lower leukemic burden; CIBMTR risk score may be useful.

AML, Acute myeloid leukemia; *APL,* acute promyelocytic leukemia; *CBF,* core binding factor; *CIBMTR,* Center for International Blood and Marrow Transplant Research; *CN,* cytogenetically normal; *CR1,* first complete remission; *CR2,* second complete remission; *haplo,* haploidentical; *MDS,* myelodysplastic syndrome; *MMUD,* mismatched unrelated donor; *MRD,* matched related donor; *MUD,* matched unrelated donor; *t-AML,* therapy-related AML; *UCB,* umbilical cord blood; *WBC,* white blood cell.

[a]If no sibling donor available.

[b]If no timely matched donor available.

From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

sion and restore normal bone marrow function. Remission is defined as blasts <5% in the bone marrow, absolute neutrophils (ANC) of >1000/mcl, platelets >100,000/mcl, and transfusion independence. Complete remission with incomplete marrow recovery (CRi) indicates absence of leukemic blasts in the marrow but persistent cytopenias.

3. Consolidation therapy, typically some form of intensive chemotherapy or stem cell transplant therapy intended to prevent relapse.
4. Hyperleukocytic symptoms are typically seen with WBC >100,000/ml. Leukapheresis requires catheter placement and pheresis but spares tumor lysis. Rapid cytoreduction with chemotherapy (hydroxyurea 3 to 6 g orally or cytarabine) is often adequate and easier but risks tumor lysis. Optimal management is therefore individualized.
5. Tumor lysis syndrome (TLS) is associated with a rise in uric acid, potassium, and serum phosphate, the last causing a reciprocal fall in calcium. The metabolic changes may result in renal failure, cardiac dysrhythmias, muscle spasms (due to low calcium), seizures, and death (a more detailed discussion is in the section on acute lymphocytic leukemia).
6. The mainstays of therapy for AML are medications dating from the 1970s—daunorubicin and cytarabine—with few medications having meaningful impact on therapy in the last four decades. In 2017, the U.S. FDA approved four new agents, including three targeted agents, for treatment of AML. The role of these agents and their relation to standard therapy is outlined below.
7. Induction chemotherapy typically consists of daunorubicin 60 or 90 mg/m^2 IV for 3 days and cytarabine (Ara-C) 100 or 200 mg/m^2/day as continuous infusion for 7 days ("7+3"). Success rates are 60% to 80% and have been better in recent trials. Other agents that are used include etoposide, idarubicin, fludarabine, and cladribine. Bone marrow examination is usually performed at day 14 of therapy to assess the response.
8. Gemtuzumab ozogamicin (GO, Mylotarg) is an antibody-drug conjugate binding an anti-CD33 antibody to the chemotherapeutic agent calicheamicin that was approved in 2017 for therapy of newly diagnosed CD33+ AML. In newly diagnosed AML, the use of low-dose GO when added to standard 7+3 induction had a success rate of 81%, with 2-yr relapse-free survival improving from 22.7% to 50.3% compared with standard therapy alone. The benefit was seen in favorable and intermediate-risk patients.
9. Midostaurin was also approved in 2017 for treatment of newly diagnosed AML with mutations in the fms-related tyrosine kinase 3 *(FLT3)* gene in combination with standard induction therapy. Four-yr

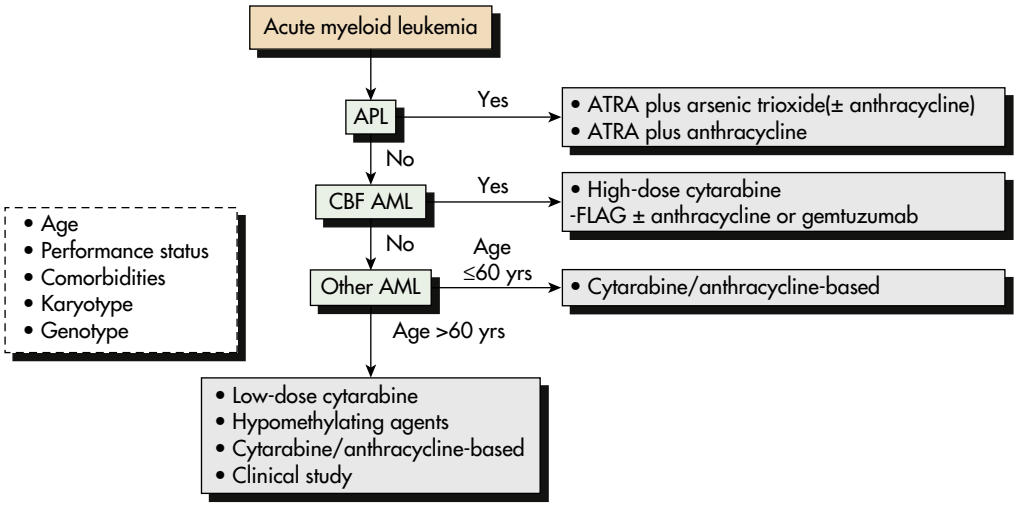

FIG. 3 General approach to acute myeloid leukemia therapy. *AML,* Acute myeloid leukemia; *APL,* acute promyelocytic leukemia; *ATRA,* all-trans retinoic acid; *CBF,* core binding factor; *FLAG*, fludarabine, cytarabine (ara-C), and granulocyte colony-stimulating factor. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

overall survival was 51.4% in FLT3-positive patients receiving midostaurin vs. 44.3% in the placebo arm, with improved durability of remissions in patients achieving remission. The optimal use of these therapies requires rapid access to genetic data at the time of diagnosis. Also approved in 2017 was CPX-351, a liposomal formulation of cytarabine and daunorubicin encapsulated in a 5:1 ratio, for patients with AML related to previous therapy (t-AML) or with AML with myelodysplasia-related change (AML-MRC). In a trial of t-AML and AML evolving from myelodysplasia or with WHO-defined myelodysplasia-related cytogenetic changes in patients ages 60 to 75 yr, CPX-351 improved survival to 9.56 mo vs. 5.95 mo with standard 7+3 induction.

10. Gilteritinib was FDA approved in 2018 for treatment of adult patients who have relapsed or refractory acute myeloid leukemia with a FLT3 mutation. Approval was based on an interim analysis of a trial, which included 138 adult patients with relapsed or refractory AML having a FLT3 ITD, D835, or I836 mutation. Gilteritinib was given orally at a dose of 120 mg daily until unacceptable toxicity or lack of clinical benefit. After a median follow-up of 4.6 mo, 21% of patients achieved complete remission (CR) or CR with partial hematologic recovery (CRh).
11. In 2018, the FDA granted accelerated approval to Venetoclax, a BCL-2 inhibitor, in combination with azacitidine or decitabine or low-dose cytarabine for the treatment of newly-diagnosed acute myeloid leukemia in adults who are age 75 yr or older, or who have comorbidities that preclude the use of intensive induction chemotherapy. The recommended Venetoclax dose depends upon the combination regimen.

- Consolidation therapy is controversial. For patients managed with chemotherapy, cytarabine 3 g/m^2 for six doses is commonly used (day 1, 3, 5), but intermediate doses (1000 to 1500 mg/m^2) for six doses appear equally effective and less toxic. Doses above 1000 mg/m^2 are poorly tolerated in patients over 60 yr because of cerebellar toxicity. Renal insufficiency also increases the risk of cerebellar toxicity from Ara-C, which can be severe.
  1. For favorable risk disease, consolidation with chemotherapy alone with two to four cycles of intermediate/high-dose cytarabine is typically given, with long-term survival of 60% to 70%.
  2. For intermediate-risk and unfavorable-risk disease, first-remission allogeneic stem cell marrow transplant is often recommended if a donor is available. If not, chemotherapy consolidation chemotherapy is offered, although the optimal therapy and schedule, especially for unfavorable disease, is uncertain.
  3. In the trial of GO as initial therapy, GO was also used in consolidation with high-dose cytarabine and daunorubicin.
  4. The role of autologous bone marrow transplant is controversial, with some evidence of decreased relapse rates after chemotherapy but no clear benefit in overall survival.
  5. Allogeneic bone marrow transplant is offered to patients with relapsed disease if a second remission can be obtained in good risk patients. It is offered to high-risk and intermediate-risk patients in first remission if a donor is available. In 2018, most patients will be able to find a donor from either a matched related donor, matched unrelated donor, mismatched unrelated donor, haploidentical donor, or cord blood donor. The Center for International Blood and Marrow Transplant Research (CIBMTR) has published data for 12,309 patients receiving an HLA-matched sibling transplant and 15,632 patients receiving a matched unrelated donor for AML between 2002 and 2012. Their disease status at the time of transplant and the donor type were found to be the best predictors of post-transplant survival. The 3-yr probabilities of survival after HLA-matched sibling transplant in this cohort was 58% ±1%, 50% ± 1%, and 24% ± 1% for patients with early, intermediate, and advanced disease, respectively. The probabilities of survival after an unrelated donor transplant were 49% ± 1%, 47% ± 1%, and 22% ± 1% for patient with early, intermediate, and advanced disease, respectively.
  6. Enasidenib, a selective inhibitor of mutated isocitrate dehydrogenase 2 (IDH-2), was approved by the FDA in 2017 for relapsed or refractory AML with IDH-2 mutations. IDH-2 mutations are found in about 12% of AML patients. At a dose of 100 mg orally, the response rate was 40.3%, with 19.3% achieving remission, some durable. Differentiation syndrome can be seen with enasidenib, similar to therapy for APML.
  7. Ivosidenib, a selective inhibitor of isocitrate dehydrogenase-1 (IDH-1) mutation, was approved by the FDA in 2018 as the first treatment of adult patients with relapsed/refractory acute myeloid leukemia with an IDH-1 mutation. Approval was based on results from a phase 1, open-label, single-arm, multicenter, dose-escalation, expansion trial of adult patients in this population. The primary end point was combined complete remis-

TABLE 6 Classification of Acute Myeloid Leukemia According to the Revised World Health Organization Classification (2016)

Category	Subtype/Definition*
AML with recurrent cytogenetic abnormalities	t(8;21)(q22;q22); RUNX1-RUNX1T1†
	inv(16)(p13.1q22); CBFB-MYH11†
	t(16;16)(p13.1q22); CBFB-MYH11†
	t(15;17)(q22;q12); PML-RARA† (= acute promyelocytic leukemia)
	t(9;11)(p22;q23); MLLT3-KMT2A
	t(6;9)(p23;q34); DEK-NUP214
	inv(3)(q21q26.2); GATA2, MECOM
	t(3;3)(q21;q26.2); RPN1-EVI1
	t(1;22)(p13q13); RBM15-MKL1 (megakaryoblastic)
	with mutated NPM1
	with biallelic mutations of CEBPA
AML with MDS-related changes	Morphologic features of MDS, or prior history of MDS or MDS/MPN, or MDS-related karyotype, and none of the recurrent genetic abnormalities above
Therapy-related myeloid neoplasms	Late complications of cytotoxic chemotherapy (alkylating agents, topoisomerase II inhibitors) and/or ionizing radiation therapy†
AML, not otherwise specified	AML with minimal differentiation
	AML without maturation
	AML with maturation
	Acute myelomonocytic leukemia
	Acute monoblastic/monocytic leukemia
	Pure erythroid leukemia
	Acute megakaryoblastic leukemia
	Acute basophilic leukemia
	Acute panmyelosis with myelofibrosis
Myeloid Sarcoma	
Myeloid proliferations related to Down syndrome	Transient abnormal myelopoiesis
	Myeloid leukemia associated with Down syndrome
Blastic Plasmacytoid Dendritic Cell Neoplasm	
Acute leukemia of ambiguous lineage	Acute undifferentiated leukemia
	Mixed-phenotype acute leukemia with: t(9;22)(q34;q11.2); BCR-ABL1 t(v;11q23); KMT2A rearranged
	Mixed-phenotype acute leukemia, B/myeloid, NOS
	Mixed-phenotype acute leukemia, T/myeloid, NOS
Provisional entities	AML with mutated NPM1
	AML with mutated CEBPA
	NK-cell lymphoblastic leukemia/lymphoma

AML, Acute myeloid leukemia; *MDS,* myelodysplastic syndrome; *MPN,* myeloproliferative neoplasm; *NK,* natural killer; *NOS,* not otherwise specified. For AML with recurrent genetic abnormalities, specific genes rearranged follow the chromosome rearrangement. In 2016, the *MLL* gene has been renamed *KMT2A.*

*Diagnosis of AML regardless of percentage of blasts.

†Excluded are patients with AML who have transformed from MPN.

sion and complete remission with partial hematologic improvement; the combined rate was 32.8%, and the median duration of remission was 8.2 mo.

8. Relapses after bone marrow transplant can sometimes be managed with donor lymphocyte infusions, adjustment of immune suppression, and chemotherapy (often low intensity). In general, outcomes are poor with posttransplant relapses.

- Treatment of older patients (>60 yr) is problematic, with cure rates of 10% to 15%. Older patients do worse because they are more likely to have high-risk features and less likely to tolerate therapy. Several models have been devised to identify variables that predict which patients may do well with conventional therapy versus those who will not (Table 7). Options for these patients include:
  1. Standard induction therapy is reasonable for patients likely to tolerate it. Even in the absence of cure, quality of life is often excellent in remission. More recent studies suggest that the early death rate (within 30 days of diagnosis) was lower for patients in their 70s and 80s receiving standard induction. There is no standardized approach to evaluating fitness for therapy; one algorithm is at www.aml-score.org/.
  2. Hypomethylating agents—decitabine and azacytidine—may be considered in patients unlikely to tolerate induction therapy. Azacytidine (75 mg/m^2 daily for 7 days every 28 days) and decitabine (20 mg/m^2 for 5 days every 28 days) are considered in older patients who are not considered appropriate for induction chemotherapy. Both are outpatient regimens, and decitabine especially is very well tolerated. Recent data with azacytidine suggest benefit in about 20% to 30% lasting 14 to 16 mo in responders, with equivalent results in low blast count (20% to 30% in the bone marrow) vs. higher blast count disease.
  3. Single-agent gemtuzumab ozogamicin is an option for treatment of CD33+ AML in patients considered unfit for induction. The benefit compared to best supportive care (BSC) was mainly seen in patients with CD33 expression of greater than 80% and favorable/intermediate cytogenetics (1 yr survival 22% and 37% respectively, BSC <10%), with no benefit in patients with high-risk cytogenetics.
  4. Low-dose cytarabine 20 mg/m^2 twice daily or 40 mg/m^2 daily for 10 days subcutaneously) has shown survival benefit over hydroxyurea in low-/intermediate-risk patients.
  5. In November 2018, the FDA granted the accelerated approval to venetoclax (a bcl-2 protein inhibitor) in combination with azacitidine or decitabine or low-dose cytarabine for the treatment of newly diagnosed acute myeloid leukemia in adults who are age 75 yr or older, or who have comorbidities that preclude use of intensive induction chemotherapy. The recommended venetoclax dose depends upon the combination regimen and is described in prescribing information of venetoclax.
  6. In November 2018 the FDA approved glasdegib (a small molecule inhibitor of Sonic hedgehog pathway) in combination with low-dose cytarabine (LDAC), for newly diagnosed acute myeloid leukemia in patients who are 75 yr old or older or who have comorbidities that preclude intensive induction chemotherapy. Approval was based upon a multicenter, open-label, randomized study that randomized eligible patients 2:1 to receive glasdegib, 100 mg daily, with LDAC 20 mg subcutaneously twice daily on days 1 to 10 of a 28-day cycle or LDAC alone in 28-day cycles until disease progression or unacceptable toxicity. Efficacy was established based on an improvement in overall survival, 8.3 mo for LDAC + glasdegib versus 4.3 mo for LDAC alone. HR of 0.46 (95% CI: 0.30, 0.71; p=0.0002).
  7. Oral hydroxyurea dosed to counts and cytopenias.
  8. Best supportive care.
  9. Reduced-intensity allogeneic stem cell transplant is an option for patients in remission after standard therapy. A recent meta-analysis of studies including 749 patients over 60 receiving RIT identified a 3-yr relapse-free survival of 35%.

- **Acute Promyelocytic Leukemia (APML):** APML is a distinct leukemia syndrome with very different treatment implications. Cure rates greater than 95% have been seen in current protocols in the absence of high-risk features. It is associated with t(15;17), which translocates the *PML* gene to retinoic acid receptor α (PML-RARa). Uncommon variants are t(11;17) and t(5;17). Risk groups for relapse were defined in studies using retinoic acid and chemotherapy. Patients with presenting WBC >10,000/mcl were considered high risk, patients with WBC <10,000 and platelets >40,000 were considered low risk, and all others were considered intermediate

TABLE 7 Prognostic Models in Older Patients with Acute Myeloid Leukemia

Study	Outcome	Unfavorable Characteristics
Study Alliance Leukemia	Survival Disease-free survival	CD34 expression >10% WBC >20 × 10^9/L Age >65 yr LDH >700 U/L NPM1 status wild-type[a]
UK Medical Research Council	Survival	Adverse cytogenetic group Elevated WBC[b] Poor performance status[b] Older age[b] Secondary AML
Acute Leukemia French Association	Survival	High-risk cytogenetics ± Age ≥75 yr Performance status ≥2 WBC ≥50 × 10^9/L
MD Anderson Cancer Center	Remission rate Induction mortality Survival	Age ≥75 yr Secondary AML[c] AHD duration ≥6[c] (12) mo Treatment outside LAFR Unfavorable cytogenetics WBC ≥25 × 10^9/L[c] Hemoglobin ≤8 g/dl[c] Creatinine >1.3 mg/dl Performance status >2 LDH >600 U/L[d]
Hematopoietic Cell Transplantation Comorbidity Index	Early mortality Survival	Dyspnea Coronary artery disease, CHF, MI, or EF <50% Chronic hepatitis, elevation of bilirubin and/or transaminases Cirrhosis Elevations of creatinine, dialysis, renal transplant Secondary AML Depression/anxiety requiring therapy Continued use of antimicrobial therapy after day 0 BMI >35 kg/m^2

AHD, Antecedent hematologic disorder; *AML,* acute myeloid leukemia; *BMI,* body mass index; *CHF,* congestive heart failure; *EF,* ejection fraction; *LAFR,* laminar air flow room (isolation floor); *LDH,* lactate dehydrogenase; *MI,* myocardial infarction; *WBC,* white blood cell count.
[a]Favorable and high-risk groups were defined solely by cytogenetic aberrations. Above factors served to further divide the intermediate risk group into good intermediate versus adverse intermediate.
[b]As continuous variables.
[c]Only significant for prediction of remission.
[d]Only significant for prediction of survival.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

risk. In current protocols, high-risk patients receive some form of intensified therapy.

- APML is a medical emergency because of the high risk of bleeding complications.
  1. All patients with APML have DIC, caused by overexpression of annexin II, (which increases generation of plasmin, degrading fibrin), elastases (which degrade fibrinogen and fibrinolytic inhibitors), and increased endothelial tissue plasminogen activator release.
  2. Early death due to hemorrhage is seen in 5% to 17% of newly diagnosed APML patients, usually intracranial or pulmonary. Risk factors include elevated WBC, increased age, and elevated creatinine.
  3. Retinoic acid rapidly stabilizes the coagulopathy of APML; consideration should be given to starting this immediately for suspected cases.
  4. Cryoprecipitate (usual dose 10 bags) to raise the fibrinogen level to 150 mg/dl and platelet transfusion to raise the count to >50,000mcl should be given as needed.
  5. Unfractionated heparin may paradoxically stop bleeding in APML by inhibiting DIC, but is rarely used in the retinoic acid treatment era.
- Diagnosis of APML.
  1. Rapid diagnosis is essential due to treatment implications.
  2. Diagnosis by classic APML blast morphology and clinical syndrome (especially DIC with low fibrinogen) is sufficient to justify starting treatment with retinoic acid pending confirmation with molecular studies. Immediate therapy with retinoic acid will rapidly stabilize the coagulopathy and help prevent catastrophic bleeding.
  3. Polymerase chain reaction for PML/RARa.
  4. FISH for t(15;17) or variants.
  5. Flow cytometry is typically distinct with lack of HLA-DR and CD34; CD13, CD33 and CD64 are usually positive.
- Therapy of APML.
  1. Emergency measures to stabilize coagulopathy as outlined previously.
  2. Patients with WBC ≤10,000 (low/intermediate risk) are treated with retinoic acid and arsenic trioxide ("differentiation therapy").
  3. Therapy of high-risk patients is less well standardized but has included intensification with cytarabine, anthracyclines, and gemtuzumab ozogamicin. A recent trial using arsenic and retinoic acid with GO demonstrated 100% 4-yr survival in high-risk patients after 30 days, emphasizing the importance of preventing early deaths in APML.
  4. Maintenance therapy for 2 yr is given in some APML protocols.
  5. Patients with high-risk disease receive central nervous system prophylaxis with intrathecal chemotherapy.
  6. Treatment of relapsed disease typically consists of autologous bone marrow transplant after obtaining second remission.
- Differentiation syndrome (DS) is a potentially fatal complication of therapy with retinoic acid and arsenic trioxide. It is associated with fever, interstitial pulmonary infiltrates, peripheral edema, pleural and pericardial effusions and renal failure; it is commonly associated with rising WBC seen in patients on differentiation therapy.
  1. Therapy for suspected differentiation syndrome is dexamethasone 10 mg/m^2 every 12 hr. Cytoreductive therapy (hydroxyurea, idarubicin) and stopping retinoic acid and arsenic are appropriate for inadequate response to dexamethasone.
  2. Prophylaxis for differentiation syndrome with dexamethasone 2.5 mg/m^2 every 12 hr has been suggested for WBC >5000 or creatinine >1.4 mg/dl. Hydroxyurea is used to keep the WBC below 10,000/mcl in some protocols.

PEARLS & CONSIDERATIONS

- The diagnosis of acute myeloid leukemia or variants is often, but not always, a medical emergency requiring rapid clinical and laboratory assessment by appropriate expertise.
- APML is a distinct clinical entity that has a high cure rate with current protocols, but which requires intensive supportive care at the time of diagnosis.

Acute Myelogenous Leukemia (Patient Information)

AUTHOR: **Todd F. Roberts, MD, FRCP(C)**

TABLE E1 Flow Cytometry Markers Used For Diagnosis of ANLL

Precursor stage	CD34, CD38, CD117, CD133, HLA-DR
Granulocytic (myeloid) markers	CD13, CD15 CD16, CD33, CD65, cytoplasmic myeloperoxidase
Monocytic markers	CD11c, CD14, CD64, CD4, CD11b, CD36, NG2 homologue
Megakaryocytic markers	CD41 (glycoprotein IIb/IIIa), CD61 (glycoprotein IIIa), CD42 glycoprotein 1b
Erythroid markers	CD235 (glycophorin A)

ANLL, Acute nonlymphocytic leukemia.

Adapted from Doehner H et al: Diagnosis and management of acute myeloid leukemia in adults, recommendations from an international expert panel, on behalf of the European Leukemia Net, *Blood* 115: 453-474, 2010.

TABLE E2 Significance of Molecular Abnormalities in Cytogenetically Normal Patients With AML

Molecular Profile	Patients	4-yr Overall Survival
Mutant CEBPA	67	62%
Mutant NPM, without FLT-3 ITD	150	60%
FLT-3 ITD present	164	24%
FLT-3 ITD absent, wild type NPM, wild type CEBPA (triple negative leukemia)	69	33%

AML, Acute myeloid leukemia; *CEBPA,* CCAAT/enhancer binding protein α gene; *FLT-3 ITD,* FMS-related tyrosine kinase gene internal tandem duplication; *NPM,* nucleophosmin gene.

Improved prognosis in patients with CEBPA mutations is limited to patients who lack FLT-3 ITD and have biallelic mutations. CEBPA mutations are seen in approximately 6% to 10% of AML cases, NPM mutations in 25% to 35% (more common in cytogenetically normal cases) and FLT-3 ITD in approximately 20% to 30% of cases.

The updated 2018 NCCN guidelines for AML risk stratification contain favorable, intermediate, and poor risk categories. Molecular abnormalities now included in this updated version in addition to NPM1, FLT3-ITD, and biallelic CEBPA mutation include TP53 mutation, mutated RUNX1, and mutated ASXL1. Molecular abnormalities validation and prognostication is a rapidly evolving field, and risk stratification should be modified on the continuous evaluation of research data. See the NCCN Guidelines Version 3.2018 AML Risk stratification for specific details.

Data from Schlenk RF et al: *N Engl J Med* 358: 1909-18, 2008, and Green CL et al: *J Clin Oncol* 28: 2739-47, 2010.

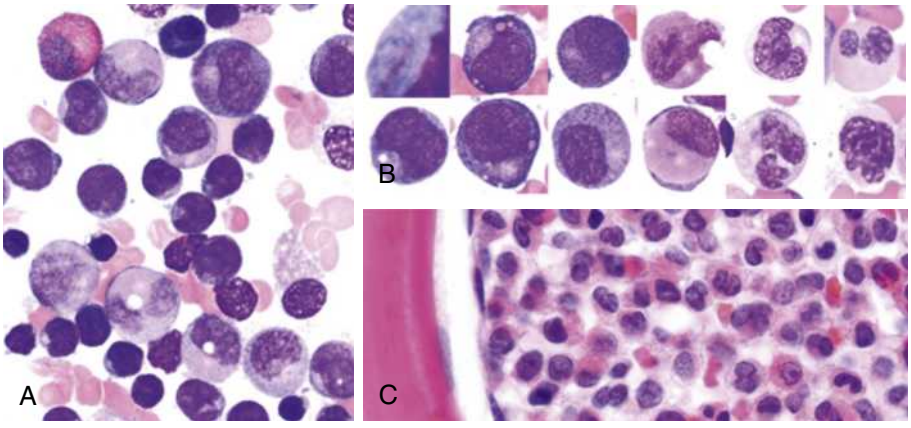

FIG. E2 Acute myeloid leukemia with t(8;21)(q22;q22), *(AML/ETO).* A, Low-power, Wright-stained bone marrow aspirate smear showing increased blasts associated with differentiating myeloid cells. **B,** Details illustrating some of the features associated with the leukemia. They include blasts with long thin Auer rods *(top left),* immature cells with abnormal eosinophilic globules *(top and bottom, second from left),* abnormal salmon-colored granulation in the maturing cells, sometimes associated with a basophilic periphery *(top and bottom, fourth from left),* and slightly abnormal features in the mature neutrophils *(far right).* Pseudo–Chédiak-Higashi granules were not seen in this case. **C,** Biopsy shows the significant degree of maturation that is sometimes seen. In some cases the blast count is less than 20%, but the diagnosis of acute myeloid leukemia still can be made with the cytogenetic finding of t(8;21). (From Hoffman R et al: *Hematology, basic principles and practice,* ed 5, Philadelphia, 2009, Churchill Livingstone.)

TABLE E5 Common Recurrent Mutations in Adult Acute Myeloid Leukemia

Gene Class	Gene	Frequency % of Patients	Clinical Significance
NPM1	*NPM1*	25-30	Improved outcome, especially without *FLT-ITD*; genetic marker for assessment of MRD
Tumor suppressor	*TP53*	8	Very poor outcome; incidence increases with older age; often associated with complex cytogenetics
DNA methylation	*DNMT3A*	18-22	Early event in leukemogenesis; incidence increases with age
	TET2	7-25	Early event in leukemogenesis; incidence increases with age; mutually exclusive of *IDH* mutations
	IDH1	7-14	*IDH1* and *2* inhibitors are in clinical development
	IDH2	8-19	Incidence increases with age
Activated signaling	*FLT3-ITD*	20	Associated with high WBC count and unfavorable outcomes, particularly if high allelic ratio; may benefit from *FLT3* inhibitor and HCT in first remission
	KIT	<5	Mostly detected in core binding factor AML; associated with worse prognosis in t(8;21) AML
	NRAS	15	Efforts to target have so far failed
Myeloid transcription factor	*RUNX1*	5-15	Poor outcome; associated with autosomal dominant predisposition syndrome; incidence increases with age
	CEBPA	6-10	Biallelic *CEBPA* mutations associated with favorable outcome; associated with familial AML
Chromatin modifier	*ASXL1*	5-17	Early event in leukemogenesis; increases with age; predictive of inferior outcome

AML, Acute myeloid leukemia; *HCT,* hematopoietic cell transplantation; *MRD,* minimal residual disease; *WBC,* white blood cell.

Acute Pelvic Pain in Women

BASIC INFORMATION

DEFINITION

Acute pelvic pain in women is defined as pain in either the pelvis or the bilateral lower quadrants of the abdomen that has been present less than 3 months and is usually sudden in onset.

SYNONYMS

Acute lower abdominal pain
Acute suprapubic pain

ICD-10CM CODE

R10.2 Pelvic and perineal pain/acute female pelvic pain/pelvic pain, acute

EPIDEMIOLOGY & DEMOGRAPHICS

- Acute pelvic pain occurs in women of all ages.

PEAK INCIDENCE: Women of reproductive age report the greatest amount of acute pelvic pain.
PREVALENCE: Acute pelvic pain is a very broad term with multiple etiologies, thus not lending itself to a single calculable prevalence. However, the prevalence of some of the most documented common causes in the U.S. include PID (2,500,000 women with a personal history in the U.S. as of 2015), ovarian torsion (2.7% of emergent gynecologic surgeries each yr), ectopic pregnancy (0.6% to 2.1% of all pregnancies), and appendicitis (6.7% lifetime risk in women).
PREDOMINANT SEX AND AGE: Women of reproductive age report the greatest amount of acute pelvic pain.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The history and physical examination are key to narrowing the diagnosis when a patient presents with acute pelvic pain.
- Standard thorough history-taking techniques should be employed, and the patient should be asked about location, onset, severity, radiation, exacerbating and alleviating factors, as well as the quality of the pain.
- Associated symptoms such as nausea, vomiting, anorexia, vaginal discharge, dyspareunia, dysuria, hematuria, urinary frequency, fever, recent upper respiratory infection (URI) symptoms, cyclic midcycle pelvic pain, or any missed or irregular menses should also be inquired about.
- A thorough sexual history should also be taken, including form of birth control used. Patients should also be asked about any history of ovarian cysts, uterine fibroids, recent pregnancies (including ectopic pregnancies), or other pelvic infections.
- Physical examination is focused on the abdominal and pelvic examination, as described under Workup later in this chapter.

ETIOLOGY

Etiologies of acute pelvic pain are varied and depend on the age and pregnancy status of the patient. Please see differential diagnosis for further information.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

GYNECOLOGIC CAUSES:

- Pelvic inflammatory disease
- Ruptured ovarian cyst
- Adnexal mass (most pain from ovarian cysts >4 to 5 cm in size and hemorrhagic in nature)
- Ovarian torsion
- Degenerating or torsed uterine fibroid
- Mittelschmerz pain
- Tubo-ovarian abscess
- Endometriosis
- Dysmenorrhea
- Hematometra/Hematocolpos

EARLY PREGNANCY/POSTPARTUM-RELATED CAUSES:

- Miscarriage
- Ectopic pregnancy (especially with ruptured ectopic)
- Postpartum endometritis

NONOBSTETRIC OR GYNECOLOGIC CAUSES:

- Appendicitis
- Urinary tract infection
- Nephrolithiasis
- Diverticulitis
- Colitis
- Bowel obstruction
- Mesenteric lymphadenitis
- Inflammatory bowel disease
- Meckel diverticulum
- Constipation
- Hernia
- Gastroenteritis
- Musculoskeletal dysfunction
- Trauma

WORKUP

The workup of acute pelvic pain begins with a thorough history and physical examination, then targeted imaging and laboratory studies are ordered to further the diagnosis.

The pelvic examination includes vaginal speculum examination, as well as bimanual and rectovaginal pelvic examinations. During the speculum examination the patient is evaluated for any active vaginal bleeding, any vaginal or cervical discharge, and any vulvar or vaginal lesions and masses.

- Testing for gonorrhea and chlamydia should be collected via nucleic acid probe.
- The bimanual and rectovaginal examinations help elucidate the size and contour of the uterus, the presence of any adnexal masses or tenderness, and whether the patient has cervical motion tenderness.

LABORATORY TESTS

- Erythrocyte sedimentation rate (ESR)
- First and foremost, one must determine the pregnancy status of the patient. The most common pregnancy-related causes of acute pelvic pain are ectopic pregnancy (approximately 1 in 7000 spontaneously conceived pregnancies and 1 in 100 pregnancies conceived via artificial reproduction) and spontaneous or threatened miscarriage. In both of these cases, the Rh status of the patient must be determined and RhoGAM administered if she is Rh negative
  - Pregnancy testing via urine or serum
- Urinalysis will assist with the diagnosis of both acute cystitis and nephrolithiasis and urine culture should be ordered as well when appropriate. Nucleic acid probes for gonorrhea and chlamydia are very sensitive and specific tests and should be collected on any patient with pelvic pain. CBC and ESR can be utilized in the patient with suspected gastrointestinal disease, appendicitis, and pelvic infection of any kind to help determine the severity of disease

IMAGING STUDIES

- Pelvic ultrasound is the primary imaging modality for acute pelvic pain in women that is suspected to be of gynecologic origin. Ultrasound can be used to diagnose intrauterine and ectopic pregnancy (Fig. 1), uterine fibroids, adnexal masses, nephrolithiasis, and even appendicitis, thus assisting with the diagnosis of the vast majority of the differential diagnosis of acute pelvic pain in women. However, there are limitations to the test, such as the level of expertise of the individual sonographer and patient body habitus interfering with the quality of the images.
- In the case of the patient with nonfocal symptoms or an inconclusive ultrasound, computed tomography (CT) of the abdomen and pelvis can be performed. CT is highly useful in the patient with early pelvic inflammatory disease (PID) or tubo-ovarian abscess, as well as in the nonpregnant patient with appendicitis or other gastrointestinal pathology not seen on ultrasound.
- Magnetic resonance imaging (MRI) also plays a role when CT is unable to discern whether a mass in the pelvis is of uterine or adnexal origin such as with a degenerating fibroid or when one must further characterize an ovarian mass. MRI is also extremely helpful in the pregnant patient who presents with many signs and symptoms of appendicitis but has an inconclusive ultrasound result. Pediatric patients are also excellent candidates for MRI when ultrasound is inconclusive. Lower levels of ionizing radiation and its excellent diagnostic capabilities make it a very useful test in this population.

TREATMENT

NONPHARMACOLOGIC THERAPY

- The underlying cause of acute pelvic pain cannot always be diagnosed with history, exam, laboratory, and imaging studies alone. In many cases, diagnostic laparoscopy is necessary to complete the diagnosis. In fact, even when the diagnosis seems sure, laparoscopy can reveal an entirely different finding as was illustrated in one study where

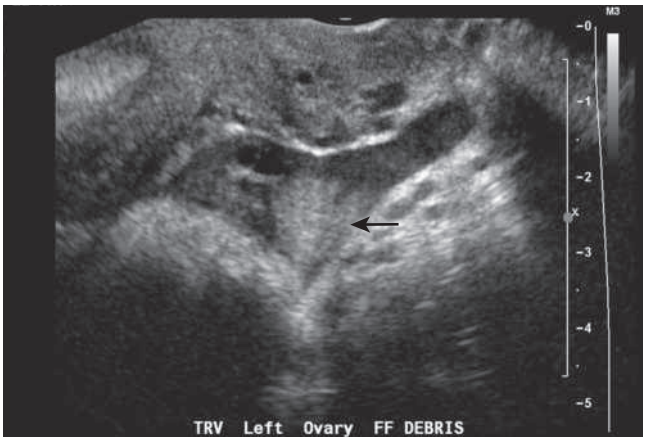

FIG. 1 A sonographic image of a 23-year-old patient with a ruptured ectopic pregnancy. The free fluid containing echogenic debris representing blood is seen in the cul-de-sac *(arrow).* (From Soto JA, Lucey BC: *Emergency radiology, the requisites,* ed 2, Philadelphia, 2017, Elsevier.)

just over half of women clinically diagnosed with appendicitis actually had the disease.

- The practitioner should not hesitate to take the patient with unstable vital signs and suspected intraabdominal bleeding or findings suggestive of ruptured appendix to the operating room. When one's clinical suspicion is quite high for such diagnoses, laboratory data and imaging studies should be forgone to expedite getting the patient the surgical interventions she needs.

ACUTE GENERAL Rx

The initial treatment of the woman with acute pelvic pain must be tailored to the underlying cause. However, as the workup is in progress, her pain must be managed. Although narcotic pain medications are sometimes initially necessary to control pain, NSAIDs are the traditional first-line pharmacotherapy for the patient with pelvic pain of an inflammatory nature. Such medications are highly useful in cases of endometriosis, dysmenorrhea, nonsurgical cases of ovarian masses and ruptured ovarian cysts, spontaneous miscarriage, nephrolithiasis, musculoskeletal dysfunction, and PID/tubo-ovarian abscess. Heat and ice can also be employed as needed for additional symptomatic relief in the appropriate patient.

CHRONIC Rx

Once a diagnosis is made, treatment is based on the underlying cause of the pain. Most patients are managed on a combination of NSAID and narcotic pain medications for a short course until the pathology has resolved or after any surgical interventions. Antibiotic therapy is routinely included in the case of an infectious cause.

REFERRAL

Patients with pain lasting greater than 3 to 6 months should be seen by a specialist in the appropriate field—gynecology, gastroenterology, general surgery, or musculoskeletal medicine—for further workup and management of their now chronic pelvic pain. Referral should also be considered when the underlying cause of pain cannot be found.

PEARLS & CONSIDERATIONS

A solid knowledge of the differential diagnosis of acute pelvic pain in women and a thorough history and physical examination will lead the practitioner to the underlying cause in the vast majority of cases. But all women who present with acute pelvic pain MUST have a pregnancy test as a part of their initial workup. If imaging is needed, pelvic ultrasound is an excellent tool and should be utilized first before CT and MRI in most cases.

Acute Respiratory Distress Syndrome PTG

BASIC INFORMATION

DEFINITION

Acute respiratory distress syndrome (ARDS) is a form of noncardiogenic pulmonary edema that results from acute damage to the alveoli. It is characterized by acute diffuse infiltrative lung lesions with resulting interstitial and alveolar edema, severe hypoxemia, and respiratory failure. The cardinal feature of ARDS, refractory hypoxemia, is caused by formation of protein-rich alveolar edema after damage to the integrity of the lung's alveolar-capillary barrier.

The definition of ARDS based on the American–European Consensus Conference (AECC) from 1994 included the following components:

1. The syndrome must present acutely
2. A ratio of Pa_{O_2} to Fi_{O_2} ≤200 regardless of the level of positive end expiratory pressure (PEEP)
3. The detection of bilateral pulmonary infiltrates on frontal chest radiograph
4. Absence of congestive heart failure (pulmonary artery wedge pressure [PAWP] ≤18 mm Hg or no clinical evidence of elevated left atrial pressure on the basis of chest radiograph or other clinical data)

The Berlin definition of ARDS (Table 1) adopted in 2011 addresses some of the limitations of the AECC definition and establishes the following criteria for ARDS:

- Timing: Within 1 week of a known clinical insult or new or worsening respiratory symptoms
- Chest imaging (chest x-ray or computed tomography [CT] scan): Bilateral opacities, not fully explained by effusions, lobar/lung collapse, or nodules
- Origin of edema: Respiratory failure not fully explained by cardiac failure or fluid overload. Need objective assessment (e.g., echocardiography) to exclude hydrostatic edema if no risk factor present
- Oxygenation (if altitude is higher than 1000 m, the correction factor should be calculated as follows: [Pa_{O_2}/Fi_{O_2} × {barometric pressure/760}]
- Mild: 200 mm Hg < Pa_{O_2}/Fi_{O_2} ≤300 mm Hg with PEEP or CPAP ≥5 cm H_2O (this may be delivered noninvasively in the mild ARDS group)
- Moderate: 100 mm Hg < Pa_{O_2}/Fi_{O_2} ≤200 mm Hg with PEEP or CPAP ≥5 cm H_2O
- Severe: Pa_{O_2}/Fi_{O_2} ≤100 mm Hg with PEEP or CPAP ≥5 cm H_2O

SYNONYMS

ARDS
Adult respiratory distress syndrome

ICD-10CM CODE
J80 Acute respiratory distress syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

- More than 150,000 ARDS cases/yr in the U.S. 7.1% of all patients admitted to an intensive care unit (ICU) and 16.1% of all patients on mechanical ventilation develop ARDS.
- An international study of 50 countries revealed that 10% of those admitted to an ICU fulfilled criteria for ARDS, and of these, 93% developed it within 48 hours of admission. The study reinforced the notion that ARDS is underrecognized.
- Black, Hispanic, and other patients belonging to racial minorities in the United States were observed to exhibit significantly higher in-hospital sepsis-related respiratory failure and associated mortality.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Signs and symptoms:
  1. Dyspnea
  2. Chest discomfort
  3. Cough
  4. Anxiety
- Physical examination:
  1. Tachypnea
  2. Tachycardia
  3. Hypertension
  4. Paradoxical breathing and use of accessory muscles
  5. Coarse crepitations or crackles of both lungs
  6. Fever may be present if infection is the underlying etiology

ETIOLOGY

- Sepsis (>40% of cases)
- Aspiration: Near-drowning, aspiration of gastric contents (>30% of cases)
- Trauma (>20% of cases)
- Pneumonia (aspiration of gastric contents and sepsis together account for more than 85% of cases of ARDS in recent clinical trials)
- Multiple transfusions, blood products
- Drugs (e.g., overdose of morphine, methadone, heroin; reaction to nitrofurantoin)
- Noxious inhalation (e.g., chlorine gas, high O_2 concentration)
- Post-resuscitation
- Cardiopulmonary bypass
- Burns
- Pancreatitis
- A history of chronic alcohol abuse significantly increases the risk of developing ARDS in critically ill patients
- Table 2 describes risk factors associated with development of ARDS

TABLE 1 2012 Berlin Definition of Acute Respiratory Distress Syndrome (All Components Must Be Present)

Timing	Within 1 week of a known clinical insult or new/worsening respiratory symptoms		
Chest imaging	Bilateral opacities—not fully explained by effusions, lobar/lung collapse, or nodules		
Origin of edema	Respiratory failure not fully explained by cardiac failure or fluid overload; need objective assessment (e.g., echocardiography) to exclude hydrostatic edema if no risk factor for ARDS is present		
Oxygenation	*Mild ARDS*	*Moderate ARDS*	*Severe ARDS*
	200 < Pa_{O_2}/Fi_{O_2} ≤300 with PEEP or CPAP ≥5 cm H_2O	100 < Pa_{O_2}/Fi_{O_2} ≤200 PEEP ≥5 cm H_2O	Pa_{O_2}/Fi_{O_2} ≤100 with PEEP ≥5 cm H_2O

ARDS, Acute respiratory distress syndrome.

TABLE 2 Risk Factors Associated with Development of Acute Lung Injury and Acute Respiratory Distress Syndrome

Direct Lung Injury	Indirect Lung Injury
Pneumonia	Sepsis
Aspiration of gastric contents	Multiple trauma
Pulmonary contusion	Cardiopulmonary bypass
Fat, amniotic fluid, or air emboli	Drug overdose
Near-drowning	Acute pancreatitis
Inhalational injury	Transfusion of blood products
Reperfusion pulmonary edema	

From Vincent JL et al: *Textbook of critical care*, ed 6, Philadelphia, 2011, Saunders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Congestive heart failure
- Interstitial lung disease (acute interstitial pneumonia, nonspecific interstitial pneumonia [NSIP], cryptogenic organizing pneumonia [COP], acute eosinophilic pneumonia, hypersensitivity pneumonia, pulmonary alveolar proteinosis)
- Connective tissue diseases, such as polymyositis
- Diffuse alveolar hemorrhage
- Lymphangitic carcinomatosis from T-cell or B-cell lymphomas
- Drug-induced lung diseases (amiodarone, bleomycin)

WORKUP

The search for an underlying cause should focus on treatable causes (e.g., infections such as sepsis or pneumonia)

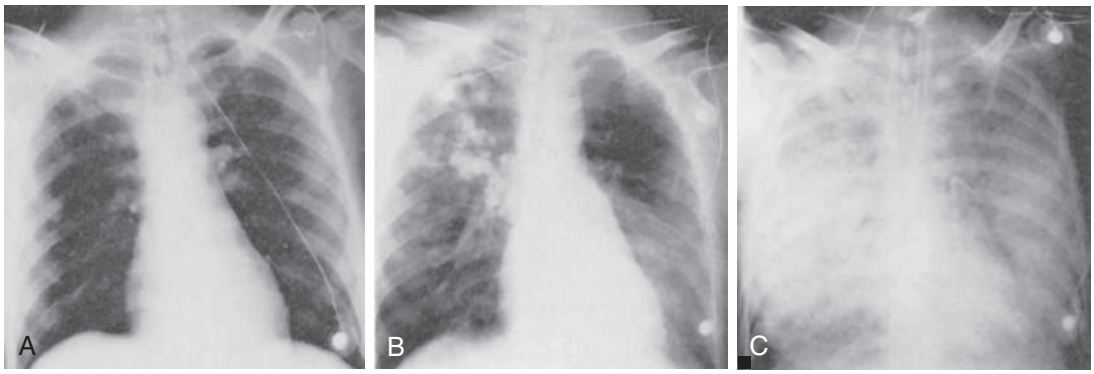

FIG. 1 Acute respiratory distress syndrome. X-ray of a young man who had sustained severe trauma and blood loss in a road traffic accident; the lungs cover a period of 5 days from a relatively normal x-ray **(A),** to bilateral infiltrates **(B),** to bilateral "whiteout" **(C),** accompanied by severe hypoxemia. A Swan-Ganz catheter for measurement of pulmonary artery "wedge" pressure (as a reflection of left atrial pressure) can be seen *in situ* on the x-ray in **C.** The patient died shortly after the last film. (From Souhami RL, Moxham J: *Textbook of medicine,* ed 4, London, 2002, Churchill Livingstone.)

- Arterial blood gases (ABGs)
- Hemodynamic monitoring
- Bronchoalveolar lavage (selected patients)

LABORATORY TESTS

- ABGs:
  1. Initially: Varying degrees of hypoxemia, generally resistant to supplemental oxygen
  2. Respiratory alkalosis, decreased Pco_2
  3. Widened alveolar-arterial gradient
  4. Hypercapnia as the disease progresses
- Bronchoalveolar lavage:
  1. The most prominent finding is an increased number of polymorphonucleocytes.
  2. The presence of eosinophilia has therapeutic implications because these patients respond to corticosteroids.
- Blood and urine cultures
- Blood work:
  1. Increased or reduced white blood cell count with left shift if concomitant infectious process
  2. Normal or mildly elevated B-type natriuretic peptide level
  3. Increased lactate level if concomitant sepsis or septic shock

IMAGING STUDIES

Chest radiograph (Fig. 1).

- The initial chest radiograph might be normal in the initial hours after the precipitating event.
- Bilateral interstitial infiltrates are usually seen within 24 hr; they often are more prominent in the bases and periphery.
- CT scan of chest: Bilateral diffuse, dense consolidations with air bronchograms.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Treatment of ARDS is supportive.

Hemodynamic monitoring:

- Can be used for the initial evaluation of ARDS (in ruling out cardiogenic pulmonary edema) and its subsequent management. However, a pulmonary catheter is not indicated in the routine management of ARDS and trials have shown that clinical management involving the early use of pulmonary artery catheters in patients with ARDS did not significantly affect mortality and morbidity rates and may result in more complications as compared with a central venous catheter.
- Although no dynamic profile is diagnostic of ARDS, the presence of pulmonary edema, a high cardiac output, and a low pulmonary capillary wedge pressure (PCWP) is characteristic of ARDS.
- It is important to remember that partially treated intravascular volume overload and flash pulmonary edema can have the hemodynamic features of ARDS; filling pressures can also be elevated by increased intrathoracic pressures or with fluid administration; cardiac function can be depressed by acidosis, hypoxemia, or other factors associated with sepsis.

Ventilatory support:

- Noninvasive positive-pressure ventilation (NIPPV) (i.e., BiPAP) should only be used in selected cases in patients with hypoxic respiratory failure. A recent randomized control study showed that high-flow oxygen by nasal cannula reduced ventilator-free days and mortality compared with NIPPV in patients with hypoxemic respiratory failure without hypercapnia. Either modality should not delay intubation and mechanical ventilation initiation in patients with rapidly progressing clinical deterioration.
- Mechanical ventilation is generally necessary to maintain adequate gas exchange (Table 3). General recommendations for ventilator settings in ARDS are described in Table 4. A low tidal volume and low plateau pressure ventilator strategy are recommended to avoid ventilator-induced injury. Assist-control is generally preferred initially with the following ventilator settings:
  1. Fio_2 1.0 (until a lower value can be used to achieve adequate oxygenation). When possible, minimize oxygen toxicity by maintaining Fio_2 at <60%.
- Tidal volume: Set initial tidal volume at 6 ml/kg of predicted body weight (PBW). Tidal volumes are reduced from 6 ml/kg of PBW to a minimum of 4 ml/kg if plateau airway pressures exceed 30 cm of water. The concept of using PBW is based on the fact that lung size depends most strongly on height and sex; PBW normalizes the tidal volume to lung size. Aim to maintain plateau pressure (Pplat) at <30 mm Hg.
- PEEP 5 cm H_2O or greater (to increase lung volume and keep alveoli open). PEEP should be applied in small increments of 3 to 5 cm H_2O (see Table 3) to achieve acceptable arterial saturation (>0.9) with nontoxic Fio_2 values (<0.6) and acceptable airway plateau pressures (<30 to 35 cm H_2O). It is important to remember that an increase in PEEP may lower cardiac output and, despite improvement in Pao_2, may actually have a negative effect on tissue oxygenation (the major determinants of tissue oxygenation are hemoglobin, percent saturation, and cardiac output). The optimal level of PEEP remains unestablished. Although higher levels of PEEP may help prevent life-threatening hypoxemia and be associated with lower hospital mortality in patients meeting criteria for ARDS, such benefit is unlikely in patients with less severe lung injury (pao_2/Fio_2 >200) and a strategy of treating such patients with high PEEP levels may be harmful. In fact, a new study published in 2017 demonstrated that the open lung approach increases mortality in patients with moderate to severe ARDS.
- Inspiratory flow: 60 L/min.
- Ventilatory rate: High ventilatory rates of up to 35 breaths/min are often necessary in patients with ARDS to achieve the desired minute ventilation because of their increased physiologic dead space and smaller lung volumes. Patients must be monitored for excessive intrathoracic gas trapping (auto-PEEP or intrinsic PEEP) that can depress cardiac output.
- Permissive hypercapnia: To maintain a low plateau pressure, a low tidal volume is

TABLE 3 Ventilator Management of Patients with Acute Respiratory Distress Syndrome

Calculate predicted body weight (PBW)	• Males: PBW (kg) = 50 + 2.3 [(height in inches) – 60] *or* 50 + 0.91 [(height in cm) – 152.4] • Females: IBW (kg) = 45.5 + 2.3 [(height in inches) – 60] *or* 45.5 + 0.91 [(height in cm) – 152.4]
Ventilator mode	• Volume assist/control until weaning
Tidal volume (Vt)	• Initial Vt: 6 ml/kg predicted body weight • Measure inspiratory plateau pressure (Pplat, 0.5 sec inspiratory pause) every 4 hours *and* after each change in positive end-expiratory pressure (PEEP) or Vt. • If Pplat is >30 cm H_2O, decrease Vt to 5 or 4 ml/kg. • If Pplat is <25 cm H_2O and Vt <6 ml/kg PBW, increase Vt by 1 ml/kg PBW.
Respiratory rate (RR)	• With initial change in Vt, adjust RR to maintain minute ventilation. • Make subsequent adjustments to RR to maintain pH 7.30-7.45, but do not exceed RR = 35/min and do not increase set rate if $Paco_2$ is <25 mm Hg.
I:E ratio	• Acceptable range, 1:1-1:3 (no inverse ratio)
Fio_2, PEEP, and arterial oxygenation	• Maintain Pao_2 = 55-80 mm Hg or Spo_2 = 88%-95% using the following PEEP/Fio_2 combinations:

Fio_2	0.3-0.4	0.4	0.5	0.6	0.7	0.8	0.9	1
PEEP	5-8	8-14	8-16	10-20	10-20	14-22	16-22	18-25

Acidosis management	• If pH is <7.30, increase RR until pH is ≥7.30 or RR = 35/min. • If pH remains <7.30 with RR = 35, consider bicarbonate infusion. • If pH is <7.15, Vt may be increased (Pplat may exceed 30 cm H_2O).
Alkalosis management	• If pH is >7.45 and patient is not triggering ventilator, decrease set RR but not below 6/min.
Fluid management	• Once patients are out of shock, adopt a conservative fluid management strategy. • Use diuretics or fluids to target a central venous pressure (CVP) of <4 or a pulmonary artery occlusion pressure (PAOP) of <8.
Liberation from mechanical ventilation	• Daily interruption of sedation • Daily screen for spontaneous breathing trial (SBT) • SBT when all of the following criteria are present: 1. Fio_2 <0.40 and PEEP <8 cm H_2O 2. Not receiving neuromuscular blocking agents 3. Patient is awake and following commands 4. Systolic arterial pressure >90 mm Hg without vasopressor support 5. Tracheal secretions are minimal, and the patient has a good cough and gag reflex
Spontaneous breathing trial	• Place patient on 5 mm Hg pressure support with 5 mm Hg PEEP *or* T-piece. • Monitor heart rate, RR, oxygen saturation for 30-90 minutes. • Extubate if there are no signs of distress (tachycardia, tachypnea, agitation, hypoxia, diaphoresis).

FiO_2, Fraction of inspired oxygen; *IBW,* ideal body weight; *$PaCO_2$,* partial pressure of carbon dioxide in the arterial blood; *PaO_2,* partial pressure of oxygen in arterial blood; *SpO_2,* saturation of arterial blood with oxygen as measured by pulse oximetry.

TABLE 4 Recommendations for Ventilator Settings in Acute Respiratory Distress Syndrome

Conventional Mechanical Ventilation		
Mode		Volume- or pressure-controlled "Airway pressure release ventilation" preferred when preservation of spontaneous ventilation is desired
Tidal volume	6-10 ml/kg	Permissive hypercapnia (increase <5 mm Hg/h) $PaCO_2$ 65-85 mm Hg well tolerated unless increased ICP Arterial pH >7.15
End-inspiratory plateau pressure	<30 cm H_2O	Above this limit, increased risks of barotrauma and air leaks
Positive end-expiratory pressure	10-15 cm H_2O	Lower PEEP levels, if heterogeneous lung injury Higher PEEP levels, if diffuse lung injury Consider early prone positioning (6-12 h)
Respiratory rate	20-60 beats/min	Adjusted to age; higher than normal may limit hypercapnia
Inspiratory/expiratory ratio	1:2 to 1:1	Check for inadvertent PEEP
FiO_2	<60%-80%	Depends on how the diseased lung may be recruited PaO_2 40-60 mm Hg, SpO_2 85%-95%
High-Frequency Oscillatory Ventilation		
Amplitude pressure	30-50 cm H_2O	To achieve visible chest vibrations
Mean airway pressure	15-30 cm H_2O	To achieve adequate chest recruitment (7 to 9 ribs)
Respiratory rate	3-10 Hz	Decrease to increase tidal volume (usually not measured)
Inspiratory/expiratory ratio	1:3 to 1:1	1:1 more appropriate in diffuse lung injury
FiO_2	<60%-80%	Depends on whether the lung may be recruited

FiO_2, Fraction of inspired oxygen; *ICP,* intracranial pressure; *$PaCO_2$,* partial pressure of carbon dioxide in the arterial blood; *PaO_2,* partial pressure of oxygen in arterial blood; *PEEP,* positive end-expiratory pressure; *SpO_2,* saturation of arterial blood with oxygen as measured by pulse oximetry.
From Fuhrman BP et al: *Pediatric critical care,* ed 4, Philadelphia, 2011, Saunders.

frequently required, leading to a reduced minute ventilation and hypoventilation with consequently a respiratory acidosis (elevated PCO_2 and reduced pH). Most patients (excluding patients with cerebral edema, acute coronary syndrome, seizures, cardiac arrhythmias, and so on) can tolerate a low pH without major consequences. Bicarbonate replacement is suggested when the pH falls to below 7.20.

- Sedation: Gamma-aminobutyric acid (GABA) receptor agonists (including propofol and benzodiazepines) have traditionally been the most commonly administered sedative drugs for ICU patients. Recent trials indicate that the alpha-2 agonist dexmedetomidine (Precedex) may have distinct advantages. At comparable sedation levels, dexmedetomidine-treated patients spent less time on ventilator, experienced less delirium, and developed less tachycardia and hypertension. The most notable adverse effect of dexmedetomidine was bradycardia. The benefits of early continuous neuromuscular blockade in patients with ARDS who are receiving mechanical ventilation remains unclear. In a recent trial among patients with moderate-to-severe ARDS who were treated with a strategy involving a high PEEP, there was no significant difference in mortality at 90 days between patients who received an early and continuous infusion of the neuromuscular blocking agent cisatracurium and those who were treated with a usual-care approach with lighter sedation targets.

ACUTE GENERAL Rx

Identify and treat precipitating conditions:

- Blood and urine cultures and trial of antibiotics in presumed sepsis (routine administration of antibiotics in all cases of ARDS is not recommended).
- Prompt repair of bone fractures in patients with major trauma.
- Crystalloid resuscitation in pancreatitis.
- Fluid management: In most patients with ARDS, fluid restriction is associated with better outcomes than a liberal fluid policy. Optimal fluid and hemodynamic management of patients with ARDS should be patient specific; in general, administration of crystalloids is recommended if a downward trend in PCWP is associated with diminished cardiac index, resulting in prerenal azotemia, oliguria, and relative tachycardia.
- Positioning the patient: Changes in position can improve oxygenation by improving the distribution of perfusion to ventilated lung regions; repositioning (lateral decubitus positioning) should be attempted in patients with hypoxemia that is not responsive to other medical interventions. Placing patients with moderate and severe hypoxemia in a prone position may improve their oxygenation. A meta-analysis that included the recent trials by Guerin et al have shown that in patients with severe ARDS, early application of prolonged (over 16 hours/day) prone-positioning sessions significantly decreases 28-day and 90-day mortality.
- Corticosteroids: Routine use of corticosteroids in ARDS is not recommended; corticosteroids may be beneficial in patients with many eosinophils in the bronchoalveolar lavage fluid or in patients with severe pneumonia. Systemic infections should be ruled out or adequately treated before administration of corticosteroids. Use of methylprednisolone has not been shown to increase the rate of infectious complications but is associated with a higher rate of neuromuscular weakness. In addition, starting methylprednisolone therapy more than 2 wk after the onset of ARDS may increase the risk of death.
- Nutritional support: Nutritional support, preferably administered by the enteral route, is necessary to maintain adequate colloid oncotic pressure and intravascular volume. The use of antioxidants and dietary oil supplements is still equivocal and cannot be recommended at this time.
- Tracheostomy: Tracheostomy is warranted in patients requiring >2 wk of mechanical ventilation; discussion regarding tracheostomy should begin with patient (if alert and oriented) and/or family members/legal guardian after 5 to 7 days of ventilatory support. Early tracheostomy (within 4 days of admission to critical care) does not limit mortality and results in many unneeded procedures (Young et al, 2013).
- Some form of deep vein thrombosis prophylaxis is indicated in all patients with ARDS.
- Stress ulcer prophylaxis with sucralfate suspension (by nasogastric tube), or proton pump inhibitors (PO or IV) or H_2 blockers (PO or IV). Should be reserved for seriously ill patients who are at high risk for this complication.
- The use of surfactant remains controversial. Patients who receive surfactant have a greater improvement in gas exchange in the initial 24-hour period than patients who receive standard therapy alone; however, the use of exogenous surfactant does not improve survival.

DISPOSITION

- Patients who survive ARDS are at risk of diminished functional capacity, mental illness, and decreased quality of life. Prognosis for ARDS varies with the underlying cause. Prognosis is worse in patients with chronic liver disease, non-pulmonary organ dysfunction, sepsis, and advanced age. ARDS survivors are at high risk for incident joblessness and substantial loss of wages, and 58% of those returning to work received disability.
- Elevated values of dead space fraction ($[Paco_2 > 2\ Peco_2]/Paco_2$; normal is <0.3) is associated with an increased risk of death.
- In ARDS, the percentage of potentially recruitable lung is variable and associated with the response to PEEP.
- Overall mortality rate varies between 32% and 45%. Most deaths are attributable to sepsis or multiorgan dysfunction rather than primary respiratory causes.
- Recent trials have shown that as compared with the current standard of care, a ventilator strategy using esophageal measures to estimate the transpulmonary pressure significantly improves oxygenation and compliance. Further trials will determine if this approach should be widely adapted.
- Strategies for treatment of life-threatening refractory hypoxemia (prone positioning, inhaled nitric acid, extracorporeal membrane oxygenation [ECMO], high-frequency oscillatory ventilation, recruitment maneuvers) may improve oxygenation, but their impact on mortality remains unproven. Use of ECMO in combination with lung-protective ventilation was found to be beneficial as a treatment strategy early in the course of ARDS related to H1N1 infection. Extracorporeal gas exchange may allow the use of low tidal volumes and lower levels of inspired oxygen and use of higher PEEP if desired. ECMO is costly and labor-intensive. The role and proper use of ECMO for patients with ARDS have not been clearly defined.
- General indications for venovenous ECMO in severe cases of ARDS are:
  1. Severe hypoxemia (e.g., ratio of Pa_{O_2} to Fi_{O_2} <80 despite the application of high levels of PEEP [typically 15 to 20 cm H_2O]) for at least 6 hr in patients with potentially reversible respiratory failure
  2. Uncompensated hypercapnia with acidemia (pH <7.15) despite the best accepted standard of care for management with a ventilator
  3. Excessively high end inspiratory plateau pressure (>35 to 45 cm H_20, according to the patient's body size) despite the best accepted standard of care for management with a ventilator

REFERRAL

Surgical referral for tracheostomy (see "Acute General Rx").

Acute Respiratory Failure (ARF)

BASIC INFORMATION

DEFINITION

Respiratory failure is a condition in which the respiratory system fails in one or both of its gas exchanging functions (oxygenation and carbon dioxide elimination). Traditionally, there are two types of acute respiratory failure: type I (hypoxic) and type II (hypercapnic). Other sources have defined a type III and a type IV; type III is respiratory failure related to atelectasis, and type IV is related to hypoperfusion of respiratory muscles in patients with shock. Type I is described in detail in another chapter (see ARDS). This chapter focuses on type II respiratory failure. Table 1 summarizes the classification of Acute Respiratory Failure.

Type II Respiratory failure is defined as an elevation in arterial carbon dioxide tension, greater than 45 mm Hg. This is directly proportional to the rate of CO_2 production and inversely proportional to the rate of CO_2 elimination by the lungs. Both hypoxemia and hypercapnia can occur at the same time, depending on the location of the underlying disorder and mechanism.

Respiratory failure can be acute (ARF) or chronic. The acute presentation occurs within minutes to hours, whereas the chronic form develops over days or longer.

SYNONYMS

Respiratory insufficiency
Hypercarbic respiratory failure
Hypoxemic respiratory failure
ARF

ICD-10CM CODES

J96.00 Acute respiratory failure
J96.01 Acute respiratory failure with hypoxia
J96.02 Acute respiratory failure with hypercapnia
J96.90 Respiratory failure, unspecified
J96.91 Respiratory failure, unspecified with hypoxia
J96.92 Respiratory failure, unspecified with hypercapnia

EPIDEMIOLOGY & DEMOGRAPHICS

- An estimated 1.9 million patients discharged from acute care hospitals nationwide meet study criteria for ARF.
- The winter months seem to be where upper and lower respiratory infections are more prevalent, and therefore when there will be a peak incidence of acute respiratory failure cases.
- Comorbid conditions, including chronic disorders of the cardiac, pulmonary, neurologic, renal, hepatic systems, and the patient's advanced age elevate the risk of mortality.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Decreased level of consciousness
- Increased cerebral blood flow, with increased intracranial pressure
- Decreased myocardial contractility
- Decreased diaphragmatic function
- Shift of the oxyhemoglobin dissociation curve to the right
- Physical signs:
  1. Dyspnea
  2. Somnolence
  3. Headaches
  4. Confusion
  5. Asterixis
  6. Coma

ETIOLOGY

See Tables 2 and 3.

DIAGNOSIS

Diagnosis is made clinically according to physical findings, and it is confirmed by arterial blood gases.

Table 4 summarizes common clues obtained from the history and physical examination.

DIFFERENTIAL DIAGNOSIS

See Table 2.

WORKUP

After supportive therapy is initiated, a careful search for the underlying cause of the respiratory failure is critical, as this may have important implications on its ultimate therapy.

LABORATORY TESTS

- Arterial blood gas (Fig. 1), showing elevated CO_2 level
- Basal metabolic panel, showing elevated bicarbonate level

IMAGING STUDIES

- Chest imaging studies include:
  1. Chest x-ray
  2. CT scan of the chest (with angiography when suspecting pulmonary embolism)
  3. Chest ultrasound

TREATMENT

The treatment of respiratory failure is initially supportive, aiming to determine first the acuity and/or severity of the presentation. Correction of the hypoxemia, hypercapnia, and management of the underlying etiology of the condition are essential to its treatment. Potential indications for mechanical ventilation are summarized in Table 5.

NONPHARMACOLOGIC THERAPY

- Treat the hypoxemia with oxygen support, which may require pressure support in the way of noninvasive ventilation (Bi-PAP) or mechanical ventilation, for the more severe cases.
- Treat hypercapnia with ventilatory support, noninvasive or invasively. The decision for either can be difficult and it is mainly based on clinical presentation, severity of

TABLE 1 Classification of Acute Respiratory Failure

	Type I	Type II	Type III	Type IV
MECHANISM OF HYPOXEMIA	Low Fio_2 ventilation/perfusion (V/Q) mismatch Shunting Reduced diffusing capacity	Hypoventilation	Shunting Hypoventilation V/Q mismatch	Hypoperfusion or inadequate oxygenation of peripheral tissues
LOCATION OF PATHOLOGICAL PROCESS	Inhaled air composition Alveolar-capillary unit Oxygen-carrying capacity of blood	Airway Central nervous system (CNS) Neuromuscular system Chest wall	Alveolar-capillary unit collapse with regional hypoventilation	Cardiovascular system Peripheral tissues
CLINICAL SYNDROMES	Cardiogenic pulmonary edema Acute respiratory distress syndrome Pneumonia Interstitial lung disease Pulmonary embolism Pulmonary hypertension Atelectasis Alveolar hemorrhage Carbon monoxide poisoning Anatomic shunts	Chronic obstructive pulmonary disease Asthma CNS depression (intoxication) CNS trauma or injury Neuromuscular disorders Skeletal disorders Obesity-hypoventilation syndrome	Thoracic or upper abdominal surgery or trauma Inadequate postoperative analgesia Pleural tumor or inflammation Trapped lung Subdiaphragmatic tumor or inflammation Obesity	Septic (distributive) shock Hypovolemic shock Cardiogenic shock Compromised cellular oxidation Hypermetabolic states

TABLE 2 Differential Diagnosis of Potential Causes of Acute Respiratory Failure

Central Nervous System	Spinal Cord, Nerves, Muscle	Chest Wall, Thoracic Cage	Increased Dead Space
Medications (anesthetics and/or opioids)	Medications	Trauma	Obstructive airways disorders
Alveolar hypoventilation	Trauma	Kyphoscoliosis	Upper: Acute epiglottitis, foreign body aspiration, tracheal tumor
Trauma	Myasthenia gravis	Flail chest	Lower: COPD, asthma, cystic fibrosis
Meningoencephalitis	Guillain-Barre syndrome	Pleural disease	
Localized tumors or vascular abnormalities of the medulla	Electrolyte abnormalities	Scleroderma	
		Morbid obesity	
Strokes affecting medullary control centers		Ascites	
Severe alkalosis		Severe ileus	

COPD, Chronic obstructive pulmonary disease.

symptoms, comorbidities, and level of acid base derangement, as well as mental status.
- Contraindications to noninvasive ventilation include respiratory arrest, hemodynamic or cardiac instability, or inability to protect the airway.
- Monitoring carbon dioxide levels has not been standardized, but a change in symptoms and or worsening in mental status can prompt a repeat in blood gas analysis.
- Worsening blood gas levels can be remediated with changes in the pressures on the noninvasive ventilator or by switching to a mechanical ventilator.

ACUTE GENERAL Rx

Ventilatory support, either invasive (mechanical ventilation) or noninvasive. Table 6 provides

TABLE 3 Pathophysiological Mechanisms That Lead to Hypoxia and Respiratory Insufficiency

Extrapulmonary processes including chest wall and skeletal abnormalities (hypoxic hypoxia)	Deficiency of oxygen in inspired air (high altitude, suffocation) Hypoactive hypoventilation (central nervous system trauma, drug toxicities, and neuromuscular and skeletal disorders) Upper airway obstruction leading to hypoventilation (trauma and angioedema)
Pulmonary etiologies (hypoxic hypoxia)	Hypoventilation caused by increased airway resistance (chronic obstructive pulmonary disease and asthma) Abnormal alveolar ventilation-perfusion ratio (pulmonary embolism, pneumonia, aspiration, and emphysema) Diminished diffusing capacity via the alveolar-capillary membrane (interstitial lung disease and pulmonary vascular disease) Pulmonary shunting (atelectasis, pneumonia, hepatopulmonary syndrome, and arteriovenous malformations)
Cardiac right-to-left shunts; e.g., atrial septal defect (hypoxic hypoxia)	—
Inadequate capacity of blood to transport oxygen (anemic hypoxia)	Anemia Hemoglobinopathies (methemoglobinemia and carbon monoxide poisoning)
Inadequate oxygen transport due to a circulatory defect (static hypoxia)	General circulatory deficiency or collapse (shock or cardiac failure) Localized circulatory deficiency (peripheral, cerebral, and coronary vessels)
Abnormal tissue capability for using oxygen (histotoxic hypoxia)	Late-stage irreversible shock Poisoning of cellular oxidation enzymes (cyanide or arsenic toxicity and heavy ethanol intoxication) Diminished cellular metabolic capacity for using oxygen (severe vitamin deficiencies; e.g., beri-beri)

Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.

TABLE 4 Common Clues Obtained from the History, Symptoms, and Clinical Examination Findings That Can Help in the Initial Diagnostic Workup and Management of Acute Respiratory Failure

History and Symptoms	Signs on Physical Examination	Diagnosis
Cough, sputum, secretions	Rales or wheezing	Pneumonia, chronic obstructive pulmonary disease (COPD) exacerbation, bronchiectasis
Sudden onset of shortness of breath	Normal auscultation and percussion, possible signs of leg swelling to suggest deep vein thrombosis	Pulmonary embolism
History of heavy smoking	Wheezing, rhonchi	Emphysema, chronic bronchitis
Orthopnea, chest pain, paroxysmal nocturnal dyspnea	Arrhythmia, peripheral edema, jugular venous distention, peripheral hypoperfusion	Congestive heart failure or acute coronary syndrome
Trauma, aspiration, blood transfusions	Diffuse crackles	Acute respiratory distress syndrome
History of allergies, wheezing or airway disease	Wheezing	Asthma, COPD
Exposure to heavy metals, handling of animals, dust or other significant environmental exposures	"Velcro" rales, clubbing	Chronic interstitial lung disease
Choking, aspiration, vomiting, dental procedures	Inspiratory stridor, poor air entry	Foreign body
Drug abuse	Constricted or dilated pupils, altered mental status, skin marks, perforated nasal septum, hypersalivation, decreased respiratory frequency	Central nervous system depression, intoxication
Exposure to a new drug/chemical or foods known to be allergenic	Swollen oral mucosa and tongue; stridor or wheezing	Angioedema, anaphylaxis
Progressive muscle weakness or immobility	Sensory abnormalities	Neuromuscular disorders
Trauma, procedures, inhalational injury	Absent breath sounds unilaterally, hypertympanic, tracheal deviation	Pneumothorax
Trauma, procedures	Absent breath sounds, dull on percussion, tracheal deviation	Hemothorax

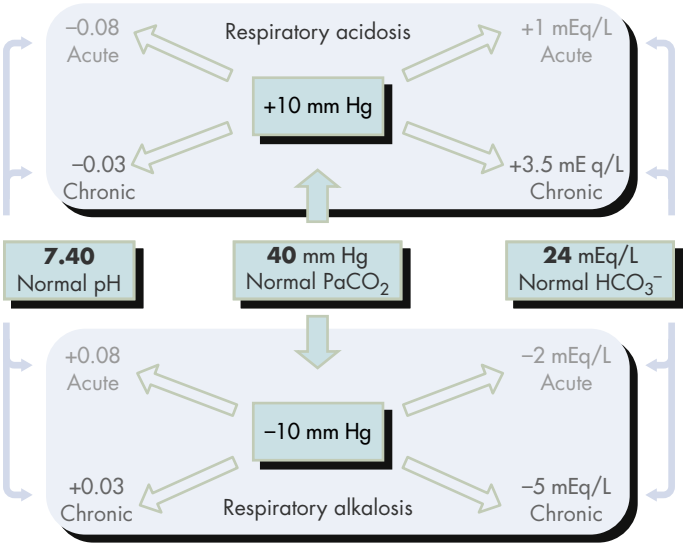

FIG. 1 Interpretation of an arterial blood gas in the setting of respiratory failure. (From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.)

an overview of features of selected modes of mechanical ventilation. Potential advantages and disadvantages of each mode are summarized in Table 7.

CHRONIC Rx

- Some patients require chronic ventilatory support, such as obesity hypoventilation syndrome patients (alveolar hypoventilation), neuromuscular disease patients (ALS), or those with chronic obstructive pulmonary disease.
- In these cases, the noninvasive form of ventilation is used during sleep.

TABLE 5 Potential Indications for Mechanical Ventilation

Physiologic Mechanism	Clinical Assessment	Normal Range	Value(s)/Finding(s) Supporting Need for Mechanical Ventilation
Hypoxemia	$P_{(A\text{-}a)}O_2$ gradient (mm Hg)	25-65	>350
	Pa_{O_2}/fi_{O_2} ratio	425-475	<300
	Sa_{O_2}	98%	<90% despite supplemental oxygen
Hypercarbia/inadequate alveolar ventilation	Pa_{CO_2}	35-45 mm Hg	Acute increase from patient's baseline pH <7.20 Mental status decline
Oxygen delivery/oxygen consumption imbalance	Elevated lactate	≤2.2 mg/dl	≥4 mg/dl despite adequate resuscitation
	Decreased mixed venous oxygen saturation	70%	<70% despite adequate acute resuscitation
Increased work of breathing	Minute ventilation	5-10 L/min	>15-20 L/min
	Dead space	0.15-0.30	≥0.5 (acute)
Inspiratory muscle weakness	NIP	80-100 cm H_2O	<20-30
	VC	60-75 ml/kg	<15-20
Acute decompensated heart failure	Jugular venous distention Pulmonary edema Decreased EF		Clinical judgment combined with the listed factors
Inadequate lung expansion	V_T (ml/kg)	5-8	<4-5
	VC (ml/kg)	60-75	<10-15
	Respiratory rate (breaths/min)	12-20	≥35

EF, Ejection fraction; *Fi_{O_2},* fraction of inspired oxygen; *NIP,* negative inspiratory pressure; *$P_{(A\text{-}a)}O_2$,* alveolar-arterial oxygen pressure difference; *Pa_{O_2},* partial pressure of oxygen; *Pa_{CO_2},* partial pressure of carbon dioxide; *Sa_{O_2},* arterial oxygen saturation; *VC,* vital capacity; *V_T,* tidal volume.

TABLE 6 Overview of Features of Selected Modes of Mechanical Ventilation

Ventilator Mode	Trigger	Control	Cycling	Inspiratory Flow
Continuous mandatory ventilation	Time	Flow or pressure	Volume or time	Selected or decelerating
Volume control/assist control (VC/AC)	Patient or time	Flow	Volume	Square, decelerating, or sinusoidal
Pressure control/assist control (PC/AC)	Patient or time	Pressure	Time	Decelerating
Synchronized intermittent mandatory ventilation	Patient or time	Pressure for patient breaths	Flow for spontaneous breaths	Decelerating for spontaneous breath
		Flow (VC) or pressure (PC) for ventilator breaths	Volume or time for ventilator breaths	Square (VC), decelerating (VC or PC), sinusoidal for spontaneous breaths
Stand-alone pressure-support ventilation	Patient	None	Flow	Decelerating

From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

TABLE 7 Potential Advantages and Disadvantages of Selected Modes of Mechanical Ventilation

Mode	Advantage(s)	Disadvantage(s)
Controlled mechanical ventilation	Rests muscles of respiration	Requires use of heavy sedation/neuromuscular blockade
Assist volume control	Reduced work of breathing Guarantees delivery of set tidal volume (unless peak pressure limit alarm is exceeded)	Potential adverse hemodynamic effects May lead to inappropriate hyperventilation and excessive inspiration pressures
Assist pressure control	Allows limitation of peak inspiratory pressures	Same as for assist volume control Potential hyperventilation or hypoventilation with lung resistance/compliance changes
Synchronized intermittent mandatory ventilation	Less interference with normal cardiovascular function	Increased work of breathing compared with assist control Patient may find it difficult to adjust to two different types of ventilator breaths
Stand-alone pressure-support ventilation	Patient comfort Improved patient-ventilator interaction Decreased work of breathing	Apnea alarm is only backup Variable patient tolerance

From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

Acute Stress Disorder

BASIC INFORMATION

DEFINITION

Acute stress disorder (ASD) features severe acute stress reactions (ASRs) that occur between 3 days to 1 month after exposure to a traumatic event (direct exposure or indirectly experienced).

SYNONYMS

ASD
ASR

ICD-10CM CODES
F43.0 Acute stress reaction
F43.11 Post-traumatic stress disorder, acute
DSM-5 CODE
308.3 Other acute reactions to stress

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: The prevalence of ASD varies according to the nature of the traumatic event. Prevalence is estimated at less than 20% in cases that do not involve a personal assault (e.g., motor vehicles accidents, traumatic brain injury, severe burns, etc.) and at 20% to 50% in cases of interpersonal trauma (e.g., sexual assault, witnessing a mass shooting).
PREDOMINANT AGE: ASD can be diagnosed at all ages. Children tend to manifest symptoms differently (e.g., frightening dreams that do not directly reflect the trauma). Young children may not report fear at the time of the trauma or when reexperiencing the trauma.
PREDOMINANT SEX: ASD occurs more frequently in females compared with males. Rate of incidence in individuals who do not identify on the gender binary is unclear.
GENETICS: Differential function of the serotonin transporter may mediate differential responses to trauma. The 5-HTTLPR may constitute a genetic candidate region. Higher rates of ASD among women may be attributable to higher rates of violence against women and sex-linked neurobiological differences in the stress response.
RISK FACTORS: Greater perceived severity of the trauma (i.e., catastrophic interpretations of the event, exaggerated appraisals of future harm, hopelessness), high levels of negative affect, avoidant coping style, history of prior trauma, lack of social support, premorbid mental disorder (e.g., preexisting anxiety or depressive disorders)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

DSM-5 criteria are met when the following criteria are satisfied:

A. Exposure to actual or threatened serious injury, death, or sexual violation in one or more of the following ways:
   1. Personally experiencing a traumatic event
   2. Witnessing a traumatic event as it occurred
   3. Learning that a traumatic event occurred to a family member or close friend
   4. Repeated or extreme exposure to the details of a traumatic event
B. Presence of nine or more of the following symptoms from any of the following five categories: (1) intrusion, (2) negative mood, (3) dissociation, (4) avoidance, and (5) arousal:
   1. Recurrent, distressing, involuntary memories of the trauma (intrusion)
   2. Recurrent distressing dreams relating to the trauma (intrusion)
   3. Flashbacks to the event, in which the individual feels/acts as if the event is recurring (intrusion)
   4. Intense or prolonged psychological distress or physiological reaction in response to cues that are reminiscent of the trauma (intrusion)
   5. Continual inability to experience positive emotions (negative mood)
   6. Altered sense of reality (dissociation)
   7. Inability to recall components of the trauma (dissociation)
   8. Avoidance of memories, thoughts, or feelings associated with the event (avoidance)
   9. Avoidance of external reminders of the event (avoidance)
   10. Sleep disturbance (arousal)
   11. Irritability and anger outbursts (arousal)
   12. Hypervigilance (arousal)
   13. Difficulties concentrating (arousal)
   14. Exaggerated startle response (arousal)
C. Symptoms typically begin immediately after the trauma and must persist for at least 3 days, and up to 1 month, following exposure to trauma. If symptoms persist for longer than 1 month, a diagnosis of posttraumatic stress disorder (PTSD) may be considered.
D. Exposure to trauma must result in clinically significant impairment in functioning.
E. Symptoms must not be attributable to a medical condition or substance use, and cannot be better explained by brief psychotic disorder.

ETIOLOGY

Factors predicting the development of ASD have not been established; however, multiple theoretical models have been proposed. Dissociative models propose that individuals minimize the emotional consequences of trauma by restricting awareness of the event to reduce fear. Cognitive perspectives propose that intentional cognitive processes (e.g., avoidance, distraction, dysfunctional appraisals, attribution of responsibility) result in pathological reactions to trauma. Biological theories focus on the immediate effects of trauma on neuronal function, including cortisol, catecholamines, glucocorticoids, serotonin, and endogenous opioids as mediating factors of the trauma response.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Adjustment disorder
- Panic disorder
- PTSD
- Obsessive-compulsive disorder
- Dissociative identity disorder
- Dissociative amnesia
- Depersonalization-derealization disorder
- Psychotic disorders
- Traumatic brain injury

WORKUP

Diagnosis is made based on individual interviews, including a history of past trauma, age at the time of the trauma, and duration of the trauma. Structured clinical interviews may be used and supplemented with standardized self-report measures. It should be noted that dissociative symptoms may prevent individuals from remembering components of the trauma, as well as remembering feelings of fear, helplessness, or horror. Clinicians often seek collateral data from other sources (e.g., family, close friends, medical providers, therapists) in diagnosing this disorder. Structured measurements such as the Stanford Acute Stress Reaction Questionnaire, Acute Stress Disorder Interview, or Acute Stress Disorder Scale, which is most useful for severity assessment, are also used by clinicians to assist with diagnosis and treatment evaluation.

LABORATORY TESTS

None indicated

IMAGING STUDIES

None indicated

TREATMENT

- Early treatment should focus on establishing a therapeutic alliance and acknowledging negative emotions (i.e., fear) of future exposure to traumatic agents.
- Resilience-focused psychosocial interventions may focus on better tolerating the distress of trauma-related memories, identifying triggers associated with traumatic events to reduce emotional reactivity or reexperiencing trauma, reducing trauma-related avoidance and sleep disturbances and nightmares, increasing social support, decreasing behaviors that interfere with daily life, limiting generalization of the danger experienced, and altering maladaptive attributions and appraisals.
- Early behavioral and educational interventions demonstrate small to moderate effects for reducing symptoms of psychological trauma.
- In cases of trauma related to experiences of interpersonal violence, safety planning is necessary for individuals who remain in unsafe situations or relationships.
- Pharmacological treatment is typically reserved for individuals who have already received psychotherapy. There are few controlled pharmacological treatment trials for ASD.
- There are currently no medications approved by the FDA for treatment of ASD. Clinicians may consider FDA-approved medications for PTSD, such as paroxetine and sertraline.

NONPHARMACOLOGIC THERAPY

- Cognitive behavioral therapy (CBT)
- Cognitive processing therapy (CPT)
- Relaxation and mindfulness

ACUTE GENERAL Rx

- Acute medication may be necessary when the individual is dangerous, agitated, or psychotic. In emergencies, short-acting benzodiazepines or neuroleptics with minimal side effects may be effective.
- Antiadrenergic agents, such as beta-blockers, may be useful for treatment of arousal.
- Brief, short-term treatment using benzodiazepines (i.e., alprazolam, clonazepam, Temazepam) may be useful for treating arousal, insomnia, and anxiety. It should be noted that prolonged use of benzodiazepines has been associated with increased risk of long-term PTSD symptoms.
- Prazosin is recommended for treatment of nightmares.
- SSRIs and other antidepressants may be useful for reexperiencing symptoms, avoidance, and hyperarousal.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Patients may find activities that increase relaxation (e.g., yoga, meditative approaches including relaxation response breathing techniques, mindfulness, and progressive muscle relaxation) useful.
- Eye movement desensitization and reprocessing (EMDR) has shown promise in alleviating symptoms in patients diagnosed with ASD; however, future research is needed to further understand the relationship between the effects of EMDR treatment and the natural recovery from traumatic stress.

DISPOSITION

Treatment should be delivered in the least restrictive environment that can ensure patient safety. Most patients with ASD can be managed in an outpatient setting. Partial or inpatient hospitalization may be necessary for crisis management and may be considered for patients who have comorbid psychiatric/medical diagnoses; who are experiencing suicidal or homicidal ideation, plans, or intention; or who are severely ill.

REFERRAL

Patients are to be treated by a mental health clinician.

PEARLS & CONSIDERATIONS

COMMENTS

- Although many individuals with ASD go on to develop PTSD, many with ASD do not. Available data at this time suggest that ASD criteria are not adequate for identifying individuals at risk for developing PTSD.
- There is evidence to suggest that the identification of subtypes of ASD, as well as a focus on high levels of arousal symptoms, could lead to better predictability of subsequent diagnoses of PTSD.

PREVENTION

Critical incident stress debriefing (CISD) after a trauma is typically administered in one 2- to 3-hour group session within 72 hours of the trauma, with the goals of allowing survivors to "vent." There is some evidence that CISD does not prevent PTSD and may contribute to poor recovery. Psychological first aid (PFA) is designed to improve outcomes after trauma by fostering safety, calmness, social connectedness, and optimism. Although PFA has received some empirical support, questions remain regarding the optimal format of administration.

BASIC INFORMATION

DEFINITION

Acute tubular necrosis (ATN) is a form of acute kidney injury (AKI) characterized by acute tubular cell injury and dysfunction. It is the most common form of AKI in the hospital. ATN may be secondary to ischemic injury, nephrotoxic injury, septic injury, or multifactorial.

SYNONYMS

ATN
Acute tubular injury
Ischemic or nephrotoxic acute renal failure (ARF)
Tubular necrosis, acute

ICD-10CM CODES

N17.0	Acute kidney failure with tubular necrosis
N17.2	Acute kidney failure with medullary necrosis
N19	Unspecified kidney failure

EPIDEMIOLOGY & DEMOGRAPHICS

- Most common cause of AKI among hospitalized patients.
- In the intensive care setting, sepsis or hypotension accounts for 50% of all ATN.
- More than 50% of cases will require renal replacement therapy.
- In-hospital mortality is about 40% to 60% among patients with AKI who require dialysis, and mortality is lower when AKI is less severe.
- Risk factors: Advanced age, diabetes mellitus, chronic kidney disease, hypertension, NSAID use, and/or other nephrotoxins, preexisting hypovolemia, or poor renal perfusion.
- Early recognition of ATN is important to prevent further tubular injury by repeated exposure to nephrotoxins.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical examination is nonspecific.
- Suspect ischemic ATN in the setting of hemorrhage, hypotension, recent surgery, and/or sepsis.
- Suspect nephrotoxic ATN in the setting of iodinated radiocontrast imaging, nephrotoxic medications, rhabdomyolysis, hemolysis, or multiple myeloma.
- Classic progression of ischemic ATN includes three phases, but can be highly variable:
  1. Initiation phase (hours to days): Renal hypoperfusion with evolving ischemia. Acute decrease in glomerular filtration rate (GFR), abrupt elevation of BUN and serum creatinine, and/or decrease in urine output
  2. Maintenance phase (1 to 2 weeks): Renal cell injury established and GFR stabilizes. At the nadir of GFR, urine output is at its lowest rate (usually 40 to 400 ml/day). ATN is complicated by hyperkalemia, metabolic acidosis, uremia, and sodium and/or fluid overload. Patients are at an increased risk of infection, and approximately 25% of deaths from ATN occur during the maintenance phase
  3. Recovery phase (>2 weeks): Tubular cell repair and regeneration, with gradual, partial or complete return of kidney function to baseline levels, frequently in association with marked osmotic diuresis and polyuria

PATHOLOGIC FINDINGS

Vacuolization and loss of brush border in proximal tubular cells, basement membrane disruption, sloughing of tubular cells, and occlusion of the tubular lumens by casts. Interstitial edema and mild leukocyte accumulation are variably present.

ETIOLOGY

- Diagnosis of exclusion. Prerenal, postrenal, and other intrinsic parenchymal causes of AKI must be ruled out first
- Injury is instigated 24 to 48 hours prior to development of AKI. Careful review of hemodynamic parameters and medications 2 to 3 days prior to decline in renal function will reveal an etiology in most cases
- Ischemic processes that contribute to ATN include hypotension, shock, prolonged prerenal azotemia, and surgery
- Renal hypoperfusion may occur without systemic hypotension (normotensive AKI)
- Medications: NSAIDs, COX-2 inhibitors, antimicrobial agents (acyclovir, foscarnet, tenofovir, cidofovir, adefovir, aminoglycosides, polymyxins, vancomycin, amphotericin B, pentamidine), calcineurin inhibitors, cisplatin, ifosfamide, angiotensin–converting-enzyme inhibitors, angiotensin II receptor blockers, and intravenous immunoglobulin
- Iodinated radiocontrast medium (contrast nephropathy)
- Hemoglobin and myoglobin (rhabdomyolysis, intravascular hemolysis)
- Heavy metals
- Synthetic cannabinoids
- Cast nephropathy secondary to multiple myeloma

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Prerenal disease (e.g., hypovolemia, cirrhosis, nephrosis, heart failure), postrenal disease (e.g., obstructive nephropathy), intrinsic renal vascular diseases (e.g., vasculitis, thrombotic thrombocytopenic purpura [TTP], hemolytic uremic syndrome [HUS], scleroderma, malignant hypertension, and renal infarction from aortic dissection), acute glomerulonephritis, acute interstitial nephritis, and atheroembolic renal disease.

LABORATORY TESTS & FINDINGS

- Urinalysis with specific gravity <1.015 and low-grade albuminuria with more severe ATN.
- Urine osmolality <450 mOsm/kg (usually <350 mOsm/kg). Urine sediment examination reveals muddy brown casts (Fig. E1) and renal tubular epithelial cells.
- Fractional excretion of sodium [FE_{Na} (%) = 100% × (U_{Na} × P_{Cr})/(P_{Na} × U_{Cr})] typically exceeds 1%.
- Multiple biomarkers for early diagnosis of ATN are currently under investigation. The FDA approved the use of urinary insulin-like growth factor-binding protein 7 and tissue inhibitor of metalloproteinases-2 for early identification of patients at risk for AKI. More clinical studies are needed to identify its use in routine clinical practice.

IMAGING STUDIES

No specific studies are indicated, but appropriate studies may be ordered to diagnose the etiology of ATN or rule out other causes of AKI (e.g., kidney ultrasound to rule out obstruction).

TREATMENT

ACUTE GENERAL Rx

The general management of ATN is the same as that for acute kidney injury. Hemodynamic

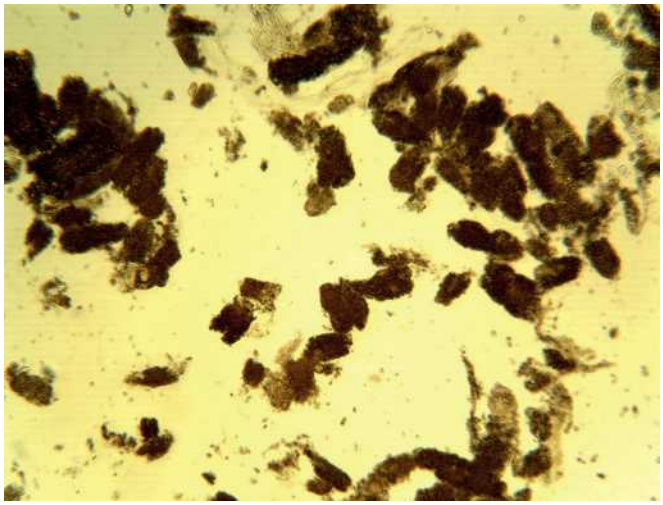

FIG. E1 Urine sediment demonstrating muddy brown, granular casts. The presence of this finding is consistent with a diagnosis of acute tubular necrosis in a patient with acute kidney injury.

abnormalities should be corrected and potentially nephrotoxic agents discontinued. Renal replacement therapy may be required until renal function is restored. There is no significant evidence that diuretic administration reduces the requirement for dialysis or improves renal recovery. However, diuretic use may facilitate fluid balance management.

DISPOSITION

Kidney function typically recovers within 2 to 3 weeks after onset. Outcomes are variable and depend on premorbid kidney function, mechanism of injury, and superimposed renal insults. Patients who are younger or nonoliguric have a better prognosis than patients who are older or oliguric. Patients may remain dialysis-dependent for up to 3 months before sufficient tubular regeneration occurs. Of patients surviving an ATN episode (~50%), approximately 5% to 10% never recover kidney function and remain dialysis-dependent.

REFERRAL

Nephrology consultation

PEARLS & CONSIDERATIONS

COMMENTS

Some patients with ATN may have FE_{Na} <1%: patients taking ACEIs, ARBs, or NSAIDs; cirrhosis; heart failure; radiocontrast injury; heme pigment-induced injury (e.g., myoglobinuria or hemoglobinuria); and early sepsis.

PREVENTION

- Aggressive intravascular volume resuscitation in hypovolemic surgical/trauma patients
- Discontinuation of potentially nephrotoxic agents
- Lowest volume of nonionic radiocontrast agents with preprocedural and postprocedural isotonic intravenous fluid administration (e.g., sodium chloride or sodium bicarbonate)

Acute Urinary Retention (AUR)

BASIC INFORMATION

DEFINITION

The acute inability to urinate when the bladder is full. This is often but not always painful, and the distended bladder may be palpable and percussible. Acute urinary retention is distinct from chronic urinary retention, a condition in which patients can still void but chronically retain a significant volume of urine in the bladder after voiding. Chronic urinary retention is not painful.

SYNONYMS

Acute urinary retention (AUR)
Urinary retention
Retaining urine

ICD-10CM CODES

R33 Retention of urine
R33.8 Other retention of urine
R33.9 Retention of urine, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- One of the most common urologic emergencies.
- Typically occurs in aging men, especially those older than 60 yrs. However, it may occur in any age group, and in either sex.
- Over a 5-yr period, AUR will occur in 10% of men older than 70 yrs and in one-third of men older than 80 yrs. There is a near-linear increase in age-specific incidence for men ages 40 to 80 yrs.

PREVALENCE: Estimates are 40/100,000 in males and 3/100,000 in females. Prevalence has increased as average lifespan has increased.
GENETICS: None known.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute inability to pass urine or only small amounts of urine.
- Pain and/or pressure in the lower abdomen and suprapubic region is typical. Low back pain may also occur. Pain may be absent, especially in older patients, patients with underlying neurologic disorders, and during chronic urinary retention.
- Palpable and/or percussible bladder may be detected.
- Suprapubic or bladder tenderness with deep palpation may be elicited.
- Increased urge to urinate with bladder palpation.
- Rarely, flank pain and costovertebral angle tenderness are present when high bladder pressures are transmitted to the ureters and kidney.
- Increased severity of lower urinary tract symptoms (LUTS) is associated with increased risk of AUR. Patients may complain of worsening LUTS prior to episode, including increased urinary urgency, incontinence, nocturia, stranguria, hesitancy, and intermittency. These symptoms usually develop between 1 day and a few weeks prior to AUR.
- Patients with cognitive deficits or inability to communicate may present with restlessness, discomfort, confusion, or delirium.
- Acute kidney injury, electrolyte abnormalities, nausea, lower extremity edema, and kidney failure may be present with delayed presentation.

ETIOLOGY

- Acute urinary retention may be spontaneous or precipitated by a triggering event. Spontaneous AUR may arise from the natural progression of bladder outlet obstruction, more commonly from benign prostatic hyperplasia (BPH), and less commonly from pelvic masses and urethral stricture disease. Conversely, precipitated AUR episodes have an identifiable triggering event, such as acute trauma, surgical procedures (e.g., spinal, orthopedic, and urologic), medications (e.g., over-the-counter [OTC] antihistamines and sympathomimetic agents commonly found in cough medications, anticholinergic drugs), excessive fluid intake (e.g., alcohol), urinary tract infection, central nervous system insults (e.g., strokes, hemorrhage, spinal cord injuries), and severe constipation. There is overlap between spontaneous and precipitated AUR, particularly when triggering events are superimposed on underlying obstructive risk factors.
- Urinary retention generally result from one of three categories: (1) Increased bladder outflow obstruction, as seen in BPH, urethral stricture disease, extrinsic compression from malignancy, constipation, and in gross hematuria where large clots can obstruct the urethra or bladder neck; (2) disruption of detrusor muscle innervation in association with diabetic neuropathy, spinal cord injury, progressive neurologic pathologies, and bladder contractile dysfunction and decompensation, secondary to prolonged outlet obstruction; and (3) bladder overdistension can lead to impaired contractility, and may result from general anesthesia, epidural anesthesia, or anticholinergic use.
- Acute retention is often multifactorial in older patients, with an underlying obstructive risk factor and acute precipitant.
- In women, obstructive factors can include benign tumors (especially, fibroid tumors); malignant tumors of pelvic, urethral, or vaginal origin; urethral strictures and urethral meatal stenosis; postpartum vulvar edema; and labial fusion. Pelvic organ prolapse, including cystocele, rectocele, and uterine prolapse, can also lead to urinary retention.
- Infection including prostatitis, urethritis, cystitis, genital herpes, and herpes zoster may also produce AUR.
- AUR is common in the postoperative period when patients are less mobile, are constipated, or have received opioid medications.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- AUR is typically self-evident to the cognitively intact patient and the treating physician.
- Chronic urinary retention.
- Pelvic masses, fluid collections, uterine fibroids, pregnancies, or ascites may be confused for a full bladder, particularly when using bedside ultrasonic bladder capacity-measuring instruments.

WORKUP

- History should focus on urologic symptoms: dysuria, hematuria, baseline voiding symptoms (caliber of stream, nocturia, sensation of incomplete emptying, double-voiding, incontinence, hesitancy), past episodes of retention, surgical history (urologic and other surgical procedures, particularly recent ones), and urologic cancer.
- History should include a complete list of prescribed and over-the-counter medications, and recent medication changes.
- Review of symptoms should include presence of fever, back pain, neurologic symptoms, and rash.
- Rectal examination for masses, fecal impaction, perineal and perianal sensation, prostate size, and sphincter tone.
- Genitourinary examination in men, with special attention for meatal stenosis and phimosis or paraphimosis.
- Pelvic examination in women with vigilance for any pelvic organ prolapse(s).
- Neurologic examination, with particular evaluation for "saddle" anesthesia (i.e., cauda equina syndrome) and pelvic sensory or motor deficits, to rule out an underlying neurologic cause.

LABORATORY TESTS

- Electrolytes, BUN, and serum creatinine.
- Urinalysis and culture, obtained via bladder or suprapubic catheterization.
- Prostate-specific antigen (PSA) testing is not helpful in AUR and may be falsely elevated after catheter placement. This test should not be routinely checked in the acute setting.

IMAGING STUDIES

- Bladder ultrasound or a bedside post-void residual urine scan ("bladder scan") can be diagnostic. However, ascites, pelvic fluid collections, body habitus, and presence of surgical implants (e.g., reservoirs for inflatable penile prostheses or artificial urinary sphincters) may confound accurate volume measurement with these devices.
- Abdominal ultrasound or computed tomography (CT) may be helpful if there is suspicion of a pelvic mass.
- CT (Fig. 1) can be helpful when high volumes are measured by a bedside bladder scan, but low volumes are returned upon bladder catheterization.
- MRI should be obtained when a spinal cord problem is suspected.

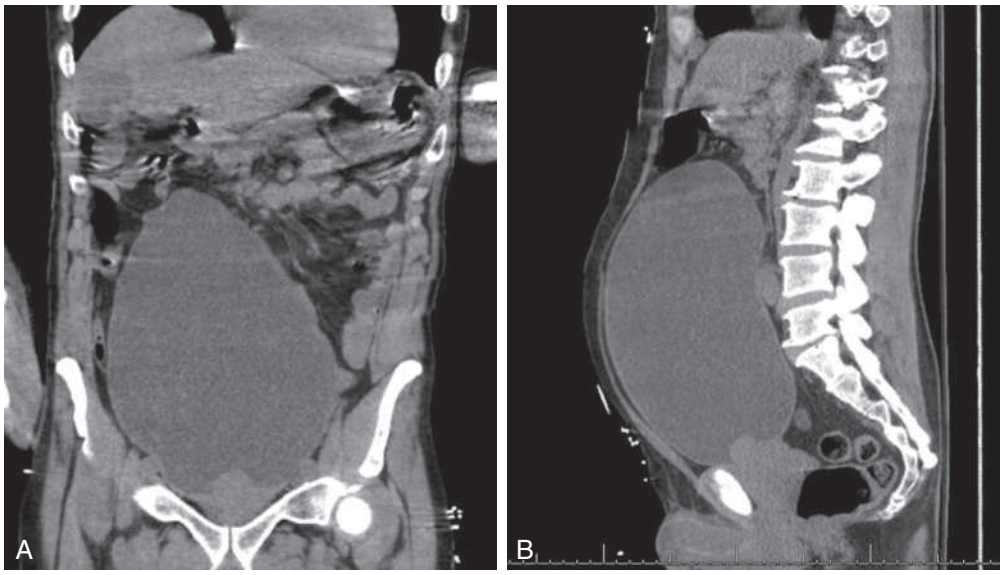

FIG. 1 Large volume urinary retention. Computed tomography images of coronal view **(A)** and sagittal view **(B)** of greatly distended bladder. The bladder extends into the mid-abdomen and above the pubic symphysis. More than 2 liters of urine was drained on bladder catheterization.

- Renal ultrasound or abdominopelvic CT may be obtained when there is kidney functional impairment and/or hydronephrosis is suspected.
- Evaluation of bladder function via urodynamic testing may be considered after initial management, particularly in females with no evidence of anatomic obstruction, or patients with longstanding obstruction and/or other neurologic conditions that affect bladder contractility.
- X-rays are of limited utility in evaluating AUR, but may show underlying constipation.

Rx TREATMENT

ACUTE GENERAL Rx

- Prompt bladder decompression and drainage is the initial management of AUR, generally by indwelling urethral catheterization. Coude-tip (angled-tip) catheters can facilitate catheter placement in men with large prostates. Clean intermittent catheterization is an option for patients with sufficient dexterity, vision, and motivation.
- Urological consultation is advised after recent genitourinary surgery, history of urethral stricture disease, or history of difficult catheterizations.
- When urethral catheterization is not possible or contraindicated, suprapubic catheter placement is required.
- Post-decompression hematuria may develop shortly after bladder drainage due to small vessel injury of the overstretched bladder wall.
- Monitor for post-obstructive diuresis, which results from a mixed osmotic and saline diuresis due to urea and salt retention during the period of obstruction.
- Avoid and/or discontinue medications that precipitate AUR (e.g., narcotics, anticholinergics, antihistamines).

CHRONIC Rx

- A voiding trial is reasonable 5 to 7 days after relief of obstruction in most patients.
- α-blockers are effective for treatment of BPH symptoms in males. These agents increase the success rate of early catheter removal and should be initiated, unless contraindicated. There is limited evidence to suggest benefit in females.
- If feasible, discontinue medications that increase the risk of AUR.
- Correct constipation and increase patient mobility.
- Inability to void after 5 to 7 days of catheterization mandates urologic consultation, with more intensive evaluation of AUR, including possible cystoscopic evaluation and/or urodynamic studies.
- Patients who unable to void after a voiding trial can either initiate clean intermittent catheterization, often 2 to 3 times a day, or have the urinary bladder catheter replaced.

DISPOSITION

- Patients can be discharged home when close follow-up is feasible, and progressive kidney injury and post-obstructive diuresis are absent
- Hospital admission if sepsis; complicated urinary tract infection; acute kidney injury; severe post-obstructive diuresis; hyperkalemia; acidemia or azotemia; or if AUR is from malignancy, hematuria, or spinal cord compression

REFERRAL

- Urologist if initial bladder catheterization is unsuccessful, or in surgical scenarios of radical prostatectomy, transurethral resection of prostate, urethral stricture surgery, and other bladder/prostate surgeries
- Urologic referral for recurrent AUR in men
- Gynecologic referral is mandatory if a pelvic mass is determined as etiology of AUR in females

PEARLS & CONSIDERATIONS

- AUR is often painful.
- Rapid bladder drainage is of paramount importance.
- Monitor for postobstructive diuresis and correct electrolyte abnormalities.
- Request urologic advice or referral for AUR after urologic surgery.

PREVENTION

Patients with BPH should be cautious regarding medications that may precipitate AUR, including antihistamines, sympathomimetics, sedatives, and anticholinergics. On a chronic basis, 5-α reductase inhibitors (e.g., finasteride, dutasteride) may reduce the risk of AUR in men with BPH and large prostates.

Adhesive Capsulitis (Frozen Shoulder) (PTG)

BASIC INFORMATION

DEFINITION

Adhesive capsulitis of the shoulder, commonly known as "frozen shoulder," is a clinical diagnosis that describes a stiff glenohumeral (GH) joint characterized by pain and restricted passive and active range of motion (ROM). The condition is often idiopathic, although secondary causes include diabetes mellitus (most common nonidiopathic cause), trauma, shoulder surgery, other endocrine disorders such as thyroid disease, autoimmune diseases, neurologic disease such as stroke and Parkinson's disease, and antiretroviral therapy used to treat HIV.

SYNONYM

Frozen shoulder

ICD-10CM CODES

M75.00	Adhesive capsulitis of unspecified shoulder
M75.01	Adhesive capsulitis of right shoulder
M75.02	Adhesive capsulitis of left shoulder

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Peaks in the mid-50s.
- Left shoulder is affected more commonly than right.

PREVALENCE: 2% to 5% in the general population and a higher incidence of up to 10% to 20% in patients with diabetes.

PREDOMINANT SEX: Females are more commonly affected than males.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The natural history of frozen shoulder occurs in three phases:

- Painful "freezing" phase: Gradual onset of severe shoulder pain that is usually worse at night and difficulty lying on the affected side. This phase may last from weeks up to 10 months. There is minimal loss of motion.
- "Frozen" or intermediate phase: Characterized by shoulder stiffness and limitation in ROM that may last for 1 yr. Pain often is present at terminal ROM during this phase. In addition to tenderness on palpation of the GH joint, there is variable loss in the degrees of active and passive shoulder abduction and external rotation.
- "Thawing" or recovery phase: Gradual improvement in pain and increase in ROM lasting for 1 to 3 yr.
- Easily confused for rotator cuff tear, especially during painful phase—distinguishing feature is diminished passive ROM, which is not found with rotator cuff tear.

ETIOLOGY

The pathology of frozen shoulder is not completely understood. The most agreed-upon theory involves a chronic inflammatory response with fibroblastic proliferation that results in thickening and contraction of the GH joint capsule, coracohumeral ligament, and rotator interval, and, ultimately, significant loss of ROM of the joint.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rotator cuff tear: May present with pain and limited ROM, but strength is more likely diminished with rotator cuff disease and passive motion is preserved.
- Calcific tendonitis: May present with painful active and passive ROM; however, testing is often limited to a single rotator cuff tendon. Calcified intratendinous bodies are visible on x-ray. An acute ruptured calcific tendonitis presents with severe, acute onset atraumatic pain. Adhesive capsulitis has a gradual onset.
- Glenohumeral osteoarthritis: May be diagnosed by degenerative changes on x-ray and marked glenohumeral crepitus on exam
- Septic arthritis: Often acute and associated with effusion.
- Trauma: Shoulder sprain, dislocation, glenoid labrum tear, rotator cuff tear.
- Cervical/neurological pathology: Evaluate all patients with shoulder complaints for cervical radiculopathy/myelopathy.

WORKUP

- Diagnosis of frozen shoulder typically is based on history and physical exam, although additional testing may help to rule out alternative diagnoses.
- Laboratory studies are not needed but can contribute to the diagnosis.
- An intra-articular injection of local anesthetic may help aid in diagnosis is there is continued loss of passive motion without pain.
- Imaging of the shoulder with plain radiography, ultrasound, MRI, or MR arthrography should be considered to rule out other pathologic conditions if there is clinical concern.
- Characteristic MRI findings include thickening of the coracohumeral ligament and the inferior joint capsule >5 mm.

TREATMENT

NONPHARMACOLOGIC THERAPY

Patient education is important for improving compliance and outcome expectations. The disease is self-limited, but many patients will experience frustration because it requires 18 to 24 months to fully resolve without treatment.

ACUTE GENERAL Rx

- Initial conservative therapy with heat and analgesics (generally NSAIDs).
- Physical therapy with passive mobilization and capsular stretching to increase ROM in the affected shoulder is an important component of therapy. Physical therapy should be supervised and last for 3 to 6 months minimum. It should be gentle and gradual and be performed multiple times/day. Strengthening of the shoulder should be avoided.
- Intraarticular corticosteroid and lidocaine injection into the glenohumeral joint—particularly effective in alleviating symptoms in short to middle-term compared to placebo. Most affective in the earlier stages.
- When conservative treatment fails (generally >4 to 6 months of stretching), the following surgical methods may be considered:
  1. Shoulder manipulation under anesthesia (rarely needed)
  2. Arthroscopic and, rarely, open capsular release

DISPOSITION

- The condition is mostly self-limited. Most patients regain 90% of shoulder motion over time and have improved pain, but symptoms can last from several months to more than 3 yr.
- Recurrence in the same shoulder is rare, although it can affect the opposite limb in up to 6% to 17% of patients. There is a higher rate of occurrence in the opposite limb in type 1 diabetics.

REFERRAL

Rheumatology or orthopedic consultation in patients who fail to respond to conservative treatment

PEARLS & CONSIDERATIONS

COMMENTS

Surgical treatment is very rarely needed for this condition. Accurate diagnosis involves a thorough assessment of active AND passive range of motion of the glenohumeral joint. Appropriate treatment is critical with corticosteroids improving symptoms more rapidly, especially during the early phases and appropriate therapeutic exercises focused on gentle, passive stretching multiple times/day.

Adnexal Masses ALG

BASIC INFORMATION

DEFINITION

The adnexa refer to the region adjacent to the uterus that includes the ovary, fallopian tube, and associated structures. Masses that arise in these regions are collectively referred to as *adnexal masses.*

SYNONYM

Pelvic mass

ICD-10CM CODES

R19.09	Other intra-abdominal and pelvic swelling, mass, and lump
C57.4	Malignant neoplasm of uterine adnexa, unspecified
N83.209	Unspecified ovarian cyst, unspecified side
N83.2	Other and unspecified ovarian cysts

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Because the etiology of adnexal masses is so broad and ranges from benign to malignant and can be gynecologic or nongynecologic in origin, a single prevalence is difficult to establish and not particularly useful in this case.

PREDOMINANT SEX AND AGE: Adnexal masses can be found in females of all ages ranging from childhood to the reproductive years to postmenopause.

RISK FACTORS: It is important to consider risk factors for malignancy. While age is the most important independent risk factor for ovarian cancer, it is also important to consider family history. The most important personal risk factor for ovarian cancer is a significant family history of breast or ovarian cancer.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The majority of adnexal masses are found incidentally when pelvic imaging is performed or on physical examination.
- Though less common, they are sometimes detected when a woman presents with acute or intermittent pelvic or abdominal pain.
- Urgent conditions such as adnexal torsion or ectopic pregnancy typically present with fairly specific symptoms such as severe pain or first trimester bleeding and should be evaluated immediately.

ETIOLOGY

The etiology of an adnexal mass depends on the organ from which the mass arises. Masses can be benign or malignant. They can be ovarian, tubal, or uterine in origin. Additionally, nongynecologic etiologies include masses arising from other organs in the pelvis such as the bladder, kidney, bowel, or peritoneum. Masses could also be due to cancer metastases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- The differential diagnosis of adnexal masses is best divided into gynecologic and nongynecologic and then further into benign and malignant.
- Gynecologic:
  1. Benign:
     a. Physiologic cyst
     b. Corpus luteal cyst
     c. Theca lutein cyst
     d. Endometrioma
     e. Cystadenoma
     f. Benign ovarian germ cell tumor (mature teratoma)
     g. Benign sex cord-stromal tumor
     h. Ectopic pregnancy
     i. Hydrosalpinx
     j. Paratubal cyst
     k. Uterine leiomyoma (pedunculated or cervical)
     l. Tubo-ovarian abscess
     m. Adnexal torsion
     n. Müllerian anomalies
  2. Malignant:
     a. Epithelial carcinoma
     b. Epithelial borderline carcinoma
     c. Germ cell tumor
     d. Sex-cord or stromal tumor
     e. Metastatic cancer
- Nongynecologic:
  1. Benign:
     a. Abscess: pelvic, appendiceal, diverticular
     b. Bladder diverticulum
     c. Ureteral diverticulum
     d. Pelvic kidney
     e. Nerve sheath tumors
  2. Malignant:
     a. Bowel neoplasm
     b. Appendiceal neoplasm
     c. Retroperitoneal sarcoma
     d. Metastasis (breast, colon, lymphoma, etc.)

WORKUP

- Evaluation of an adnexal mass (Fig. 1) begins with a thorough history that considers individual patient characteristics and the physical examination.
- A detailed gynecologic history should be obtained as well as a thorough family history and review of other risk factors.
- A full set of vital signs, the general physical appearance of the patient, and the patient's symptoms should be evaluated.
- A comprehensive physical examination including palpation of cervical, supraclavicular, axillary, and groin lymph nodes, abdominal examination, and thorough pelvic examination should be performed.
- Laboratory studies and imaging should be considered as outlined below.

LABORATORY TESTS

- A pregnancy test should be obtained on all women of reproductive age.
- If infection is suspected, CBC and cultures for gonorrhea and chlamydia should be obtained.
- Other laboratory tests that may be helpful include urinalysis and/or urine culture, fecal occult testing, and serum marker testing such as CA-125, B-hCG, AFP, and LDH if malignancy is suspected.

IMAGING STUDIES

- Transvaginal ultrasonography is the initial imaging modality of choice for evaluation of adnexal masses, including size, composition (cystic, solid, mixed), laterality, presence or absence of septations, and papillary excrescences. Abdominal ultrasonography should also be performed and can be useful if pelvic structures are distorted by prior surgery or if the mass extends above the pelvis.
- CT and MRI are not recommended for initial evaluation.
- MRI can be helpful to differentiate masses that are not ovarian in origin, especially leiomyomas.
- CT scans are most useful for evaluating metastasis if cancer is suspected as well as ascites, pelvic or periaortic lymph node enlargement, obstructive uropathy, or an alternate primary cancer site.

TREATMENT

Treatment of adnexal masses (Fig. 2) depends on the etiology of the mass, stability of the patient, and level of suspicion for malignancy.

ACUTE GENERAL Rx

- A ruptured ectopic pregnancy or ovarian torsion is a surgical emergency and warrants immediate surgical intervention. Surgical intervention may also be necessary for nongynecologic causes of adnexal masses such as appendicitis. Table 1 summarizes indications for surgery in a patient with adnexal mass.
- Ultrasound imaging with features concerning for malignancy (cyst >10 cm, papillary or solid components, irregularity, ascites, and high color doppler flow) warrants surgical intervention. Fig. 3 illustrates the management of a premenopausal woman with adnexal mass.
- Masses that appear benign but are greater than 5 cm in size are at increased risk of ovarian torsion, therefore surgical intervention needs to be considered.

CHRONIC Rx

Adnexal masses can be observed if imaging suggests benign disease or if there is a compelling reason to avoid surgical intervention. There is no established interval for ultrasound follow-up. Timing of a follow-up ultrasound should be determined on an individual basis considering patient risk factors, symptoms, premenopausal vs. postmenopausal status, and suspicion for malignancy. 6-mo follow-up is reasonable for masses larger than 5 cm, for patients

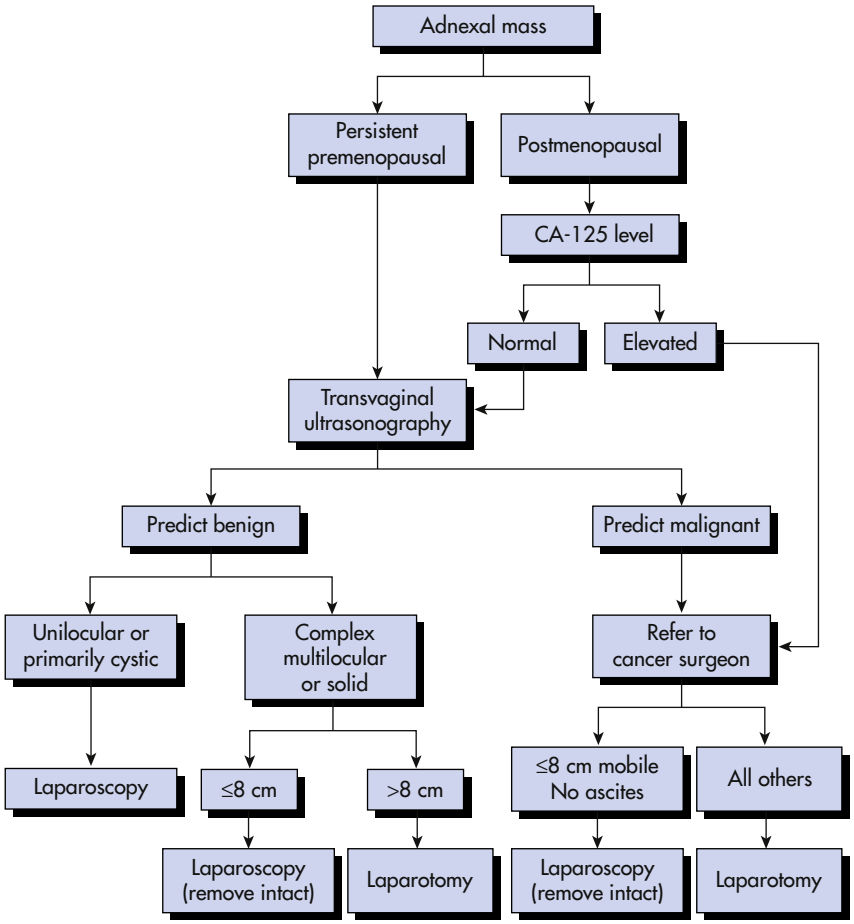

FIG. 1 Suggested management of an adnexal mass. *CA-125,* Cancer antigen 125. (From Disaia PJ et al: *Clinical gynecologic oncology,* ed 9, Philadelphia, 2018, Elsevier.)

who are symptomatic, or when concern for malignancy is higher. For patients who are otherwise asymptomatic, who have a small mass, who are premenopausal, and in whom suspicion for malignancy is low, repeat ultrasound in 1 yr is reasonable.

REFERRAL

- A referral to a gynecologic oncologist is recommended when ultrasound findings are suggestive of malignancy. Referral guidelines for women with a newly diagnosed pelvic mass are summarized in Table 2.
- A referral to general surgery or surgical oncologist should be considered if the mass is nongynecologic in origin.

TABLE 1 Adnexal Mass: Indications for Surgery

- Ovarian cystic structure >5 cm that has been observed 6-8 wk without regression
- Any solid ovarian lesion
- Any ovarian lesion with papillary vegetation on the cyst wall
- Any adnexal mass >10 cm in diameter
- Ascites
- Palpable adnexal mass in a premenarchal or postmenopausal patient
- Torsion or rupture suspected

From Disaia PJ et al: *Clinical gynecologic oncology,* ed 9, Philadelphia, 2018, Elsevier.

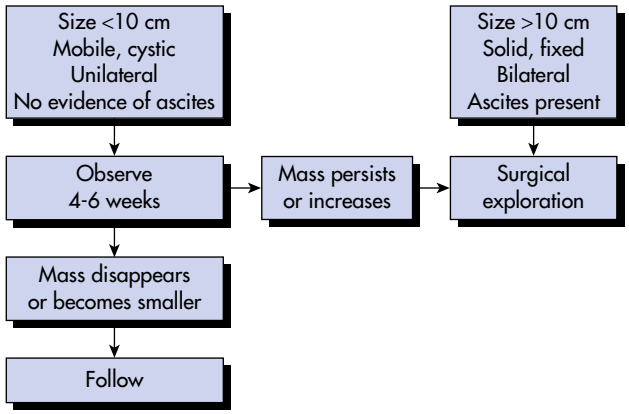

FIG. 3 Management of a premenopausal woman with an adnexal mass. (From Disaia PJ et al: *Clinical gynecologic oncology,* ed 9, Philadelphia, 2018, Elsevier.)

TABLE 2 Society of Gynecologic Oncologists and American College of Obstetricians and Gynecologists Referral Guidelines for Women with a Newly Diagnosed Pelvic Mass

Premenopausal Patients (<50 Yr Old)
CA-125 >200 units/ml
Presence of ascites
Evidence of intraperitoneal or distant metastasis (based on examination or imaging studies)
Family history (first-degree relative) of breast or ovarian cancer
Postmenopausal Patients (>50 Yr)
Elevated CA-125 level
Ascites
Evidence of intraperitoneal or distant metastasis (based on examination or imaging studies)
Family history (first-degree relative) of breast or ovarian cancer

CA-125, Cancer antigen 125.

Adrenal Incidentaloma ALG

BASIC INFORMATION

DEFINITION

Adrenal mass discovered inadvertently on thoracic or abdominal imaging, including CT, MRI, and ultrasound.

SYNONYM

Unsuspected adrenal mass

ICD-10CM CODE

D44.1 Neoplasm of uncertain behavior of adrenal gland

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Adrenal incidentalomas are found in about 5% of the population (4% to 7% on advanced imaging, up to 10% on autopsy).
PREDOMINANT SEX AND AGE: Prevalence increases with age.
GENETICS: Vary based on etiology of the incidentaloma.
RISK FACTORS: More common in Caucasian, obese, diabetic, and hypertensive patients.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Following the discovery of an incidentaloma on advanced imaging, history and physical examination should focus on identifying signs and symptoms associated with several functional tumors (Table 1).

ETIOLOGY

Up to 80% of adrenal incidentalomas are benign, nonfunctional adenomas.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Benign adenoma
- Functional adenoma (aldosteronoma, cortisol producing)
- Pheochromocytoma
- Adrenocortical carcinoma (ACC)
- Metastasis
- Lymphoma

WORKUP

- Primary focus is on establishing malignant potential and functionality of an incidentaloma (Box 1, Fig. 1).
- Functionality should be assessed in all adrenal incidentalomas >1 cm.

LABORATORY TESTS

- Low-dose dexamethasone suppression test, 24-hr urinary free cortisol, serum ACTH, and serum dehydroepiandrosterone sulfate (DHEAS)
- 24-hour urine metanephrines, fractionated catecholamines
- Basic metabolic profile
- Plasma aldosterone, renin activity levels in hypertensive patients

TABLE 1 Signs and Symptoms of Adrenal Tumor by Type

Tumor Type	Symptoms	Signs
Cortisol producing	Muscle weakness, easy bruising/bleeding, poor wound healing, decreased libido, psychiatric disturbances, insomnia, flushing, palpitations	Moon facies, buffalo hump, hirsutism, abdominal striae, central obesity with peripheral wasting, thinning of skin, hypertension, hyperglycemia
Aldosteronoma	Muscle cramping, muscle weakness, fatigue, headache, polydipsia, polyuria	Refractory hypertension, hypokalemia
Pheochromocytoma	Episodic headache, sweating, palpitations, pallor, anxiety, sense of impending doom, flushing/hot flashes	Hypertension, tachycardia, cardiac arrhythmias, acute myocardial infarction, congestive heart failure, tremor
Adrenocortical carcinoma (ACC)	Large: Mass effect Productive: Cushing syndrome, virilization	Large: None, may be able to palpate Productive: Related to the hormone produced
Secondary metastasis to the adrenal gland	Generally none related to the adrenal tumor	Findings consistent with primary tumor source, adrenal insufficiency if adrenal tissue compromised
Nonfunctional mass	Small: None Large: Vague abdominal complaints/mass effect/pain	Small: None Large: None, may be able to palpate

From Jason DS, Oltmann SC: Evaluation of an adrenal incidentaloma, *Surg Clin North Am, 99*(4), 721-729.

BOX 1 Differential Diagnosis for Adrenal Incidentaloma

Functional Tumors
Pheochromocytoma
Cortisol-producing adenoma/subclinical Cushing syndrome
Aldosteronoma
Primary adrenal hyperplasia

Nonfunctional Lesions
Nonfunctioning cortical adenoma
Myelolipoma
Adrenal hemorrhage
Adrenal cyst
Ganglioneuroma

Malignant
Adrenocortical carcinoma
Metastases to the adrenal gland

From Cameron JL, Cameron AM: *Surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

IMAGING STUDIES

- CT scan (Figs. 2 and E3) is the imaging modality of choice if not already performed.
- Patients with a history of malignancy or other history and/or physical findings concerning for metastatic disease may benefit from PET scan.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Hormonally functional incidentalomas and masses suspicious for ACC require surgical intervention.
- Nonfunctional incidentalomas can be monitored for growth but may require surgical excision depending on size of the lesion, rate of monitored growth, age of the patient, and presence of clinically significant mass effect.
- Fine-needle aspiration (FNA) should not routinely be performed on all incidentalomas; however, if the patient has a known primary lesion, the mass is nonfunctional, and there is concern for metastatic disease, FNA may be indicated.

GENERAL Rx

- Functional masses, masses suspicious for ACC, nonfunctional masses >4 cm should be referred to general or endocrine surgery
- Nonfunctional adrenal adenomas <4 cm:
  - Follow-up imaging at 6 to 12 mo
  - Surgical consultation for enlargement >1 cm

REFERRAL

- General/endocrine surgery
- Endocrinology

PEARLS & CONSIDERATIONS

COMMENTS

Most masses are nonfunctional and do not require surgery.

Adrenal Insufficiency PTG

BASIC INFORMATION

DEFINITION

Adrenal insufficiency is characterized by inadequate secretion of corticosteroids resulting from partial or complete destruction of the adrenal glands (primary adrenal failure). Inadequate secretion of cortisol from the adrenals due to critical illness and pituitary insufficiency is known as secondary cortisol deficiency.

SYNONYMS

Primary adrenocortical insufficiency
Addison disease

ICD-10CM CODES

E27.1	Primary adrenocortical insufficiency
E27.2	Addisonian crisis
E27.40	Unspecified adrenocortical insufficiency
E27.49	Other adrenocortical insufficiency
E27.3	Drug-induced adrenocortical insufficiency
E23.3	Hypopituitarism

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: 10 to 15 per 100,000 persons
PREDOMINANT SEX: Female:male ratio of 2:1

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Adrenal insufficiency may present insidiously with nonspecific symptoms. A high index of suspicion is required for diagnosis. About half of patients may present acutely with adrenal crises. Table 1 summarizes the clinical features of primary adrenal insufficiency.
- Hyperpigmentation of skin (Figs. E1 and E2) and mucous membranes is a cardinal sign of adrenal insufficiency: more prominent in palmar creases, buccal mucosa, pressure points (elbows, knees, knuckles), perianal mucosa, and around areolas of nipples
- Hypotension, postural dizziness
- Generalized weakness, chronic fatigue, malaise, anorexia
- Amenorrhea and loss of axillary hair in females

ETIOLOGY

- Autoimmune destruction of the adrenal glands (80% of cases)
- Tuberculosis (TB) (7% to 20% of cases)
- Carcinomatous destruction of the adrenal glands, lymphoma
- Adrenal hemorrhage (anticoagulants, trauma, coagulopathies, pregnancy, sepsis)
- Adrenal infarction (antiphospholipid syndrome, arteritis, thrombosis)
- AIDS (adrenal insufficiency develops in 30% of patients with AIDS, often cytomegalovirus [CMV] adrenalitis)

TABLE 1 Clinical Features of Primary Adrenal Insufficiency

Feature	Frequency (%)
Symptoms	
Weakness, tiredness, fatigue	100
Anorexia	100
Gastrointestinal symptoms	92
Nausea	86
Vomiting	75
Constipation	33
Abdominal pain	31
Diarrhea	16
Salt craving	16
Postural dizziness	12
Muscle or joint pains	13
Signs	
Weight loss	100
Hyperpigmentation	94
Hypotension (<110 mm Hg systolic)	88-94
Vitiligo	10-20
Auricular calcification	5
Laboratory Findings	
Electrolyte disturbances	92
Hyponatremia	88
Hyperkalemia	64
Hypercalcemia	6
Azotemia	55
Anemia	40
Eosinophilia	17

From Melmed SZ et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, Saunders.

- Genetic causes: Autoimmune polyglandular syndromes (APS) types 1 and 2, X-linked adrenoleukodystrophy, congenital adrenal hyperplasia
- Other: Sarcoidosis, amyloidosis, hemochromatosis, Wegener granulomatosis, postoperative, fungal infections (candidiasis, histoplasmosis)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Sepsis, hypovolemic shock, acute abdomen, apathetic hyperthyroidism in the elderly, myopathies, gastrointestinal malignancy, major depression, anorexia nervosa, hemochromatosis, salt-losing nephritis, chronic infection

WORKUP

- An early morning (8 A.M.) serum cortisol <3 mcg/dl (82.8 mmol/L) is consistent with cortisol deficiency.
- If the cortisol level is 3 to 15 mcg/dl, the diagnosis can be confirmed with the rapid adrenocorticotropic hormone (ACTH) test:
  1. Give 250 mcg ACTH (Sinachten, tetracosatrin) by IV push and measure cortisol levels at 0, 30, and 60 min.
  2. An increase in serum cortisol level to peak concentration >500 nmol/L (18 mcg/dl) indicates a normal response. Cortisol level ≤18 mcg/dl at 30 or 60 min is suggestive of adrenal insufficiency.
  3. Measure plasma ACTH. A high ACTH level (>200 pg/ml [44 pmol/L]) confirms primary adrenal insufficiency.
- Critical illness-related corticosteroid insufficiency (e.g., in sepsis) is best established with the 1-mcg ACTH stimulation test in which cortisol levels are measured at baseline and 30 min after administration of ACTH. A level <25 mcg/dl (690 nmol/L) or an increment over baseline of <9 mcg (250 nmol/L) represents an inadequate adrenal response.
- Secondary adrenocortical insufficiency (caused by pituitary dysfunction) can be distinguished from primary adrenal insufficiency by the following:
  1. Normal or low plasma ACTH level after rapid ACTH
  2. Absence of hyperpigmentation
  3. No significant impairment of aldosterone secretion (because aldosterone secretion is under control of the renin-angiotensin system)
  4. Additional evidence of hypopituitarism (e.g., hypogonadism, hypothyroidism)

LABORATORY TESTS

- Hyponatremia, hyperkalemia
- Decreased glucose
- Increased BUN/creatinine ratio (prerenal azotemia)
- Mild normocytic, normochromic anemia, neutropenia, lymphocytosis, eosinophilia (significant dehydration may mask hyponatremia and anemia), hypercalcemia, metabolic acidosis

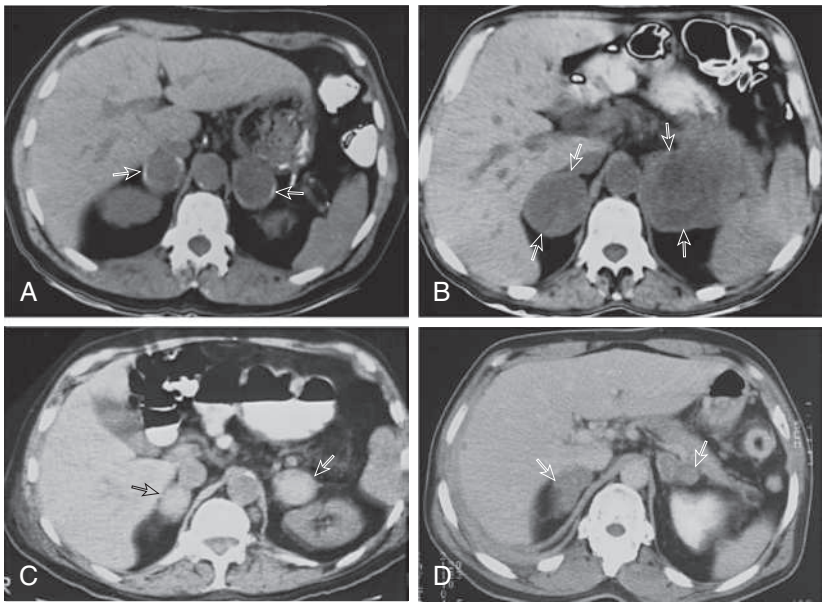

FIG. 3 Computed tomographic (CT) scans of patients with primary adrenal insufficiency. The affected adrenal glands are indicated by arrows. **A,** CT scan of a 59-year-old man with histoplasmosis. Notice the subcapsular calcium in both glands. **B,** CT scan of a 59-year-old man with metastatic melanoma. **C,** CT scan of an 80-year-old man with bilateral adrenal hemorrhage resulting from anticoagulation for pulmonary emboli. **D,** Bilateral adrenal tuberculomas in a 79-year-old man with tuberculosis affecting the urogenital tract. (**A** and **B** courtesy Dr. William D. Salmon, Jr.; **C,** courtesy Dr. Craig R. Sussman.) (From Melmed S, Polonsky KS, Larsen PR, Kronenberg HM: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, Saunders.)

- A morning cortisol level >500 mmol/L (18 mcg/dl) generally excludes the diagnosis whereas a level <165 mmol/L (6 mcg/dl) is suggestive of Addison disease and a level <3 mcg/dl requires further evaluation (see "Workup")
- Additional evaluation may include 21-hydroxylase antibodies present in 90% of autoimmune adrenalitis cases. If negative, obtain CT scan of adrenal glands
- PPD or QuantiFERON Gold test to rule out TB

IMAGING STUDIES

- Imaging is not necessary for diagnosis but may help identify potential causes.
- Abdominal CT scan (Fig. 3): Small adrenal glands generally indicate either idiopathic atrophy or longstanding TB, whereas enlarged glands are suggestive of early TB or potentially treatable diseases.
- Chest radiograph may reveal a small heart (Fig. E4).
- Abdominal radiograph: Adrenal calcifications may be noted if the adrenocortical insufficiency is secondary to TB or fungal infection.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Perform periodic monitoring of serum electrolytes, vital signs, and body weight; liberal sodium intake is suggested.
- Periodic measurement of bone density may be helpful in identifying patients at risk for the development of osteoporosis.
- Patients should carry a MedicAlert bracelet and an emergency pack containing hydrocortisone 100-mg ampule, syringe, and needle.
- Patients and partners should be educated on how to give IM injection in case of vomiting or coma.

ACUTE GENERAL Rx

- Adrenal crisis is an acute complication of adrenal insufficiency characterized by circulatory collapse, dehydration, nausea, vomiting, hypoglycemia, and hyperkalemia.
  1. Draw plasma cortisol level; do not delay therapy while waiting for confirming laboratory results.
  2. Administer hydrocortisone 100 mg IV immediately, followed by 100 to 200 mg of hydrocortisone every 24 hours administered as a continuous infusion or divided into 3 or 4 doses; if patient shows good clinical response, gradually taper dosage and change to oral maintenance dose (usually prednisone 7.5 mg/day).
  3. Provide adequate volume replacement with D_5NS solution until hypotension, dehydration, and hypoglycemia are completely corrected. Large volumes (2 to 3 L) under continuous cardiac monitoring may be necessary in the first 2 to 3 hr to correct the volume deficit and hypoglycemia and to avoid further hyponatremia.
- Identify and correct any precipitating factor (e.g., sepsis, hemorrhage).

CHRONIC Rx

- Give hydrocortisone 15 to 20 mg PO every morning and 5 to 10 mg in late afternoon or prednisone 5 mg in morning and 2.5 mg hs.
- Give oral fludrocortisone 0.05 mg/day to 0.20 mg/day. This mineralocorticoid is necessary if the patient has primary adrenocortical insufficiency. The dose is adjusted based on the serum sodium level and the presence of postural hypotension or marked orthostasis.
- Instruct patients to increase glucocorticoid replacement in times of stress and to receive parenteral glucocorticoids if diarrhea or vomiting occurs. Typical supplementation varies from 25 mg PO qd of hydrocortisone for minor medical and surgical stress to 50 to 100 mg IV hydrocortisone q8h for sepsis-induced hypotension or shock.
- The administration of dehydroepiandrosterone (DHEA) is controversial due to lack of robust data. It is not indicated in men but may be considered in women with primary adrenal failure. A dose of 50 mg PO qd may improve well-being and sexuality in women with adrenal insufficiency.
- Patients with concomitant hypothyroidism should be treated with glucocorticoids first before correcting hypothyroidism because correction of thyroid hormone deficiency will accelerate cortisol clearance and can precipitate adrenal crisis.

BASIC INFORMATION

DEFINITION

Adult-onset Still disease (AOSD) is a rare systemic inflammatory disorder of uncertain etiology, first described by George Frederic Still in 1897 as an insidious polyarthritis marked by episodes of fever, lymphadenopathy, and splenomegaly. AOSD is primarily characterized by transient fever, evanescent skin rash, arthralgias/arthritis, hepatosplenomegaly, and elevated serum ferritin. A prodromal sore throat is seen in up to 70% of cases. Daily high-spiking fever is among the most striking manifestations and may be accompanied by transitory salmon-colored maculopapular rash. Myalgias and arthralgias are nearly universal, and inflammatory arthritis may ultimately result in joint destruction.

SYNONYMS

Still disease
Systemic juvenile idiopathic arthritis (systemic JIA)
Wissler syndrome/Wissler-Fanconi syndrome
AOSD

ICD-10CM CODE
M06.1 Adult-onset Still disease

EPIDEMIOLOGY & DEMOGRAPHICS

The rarity of AOSD precludes definite epidemiologic data. Prevalence ranges from 1 to 34 per 1,000,000. Incidence is 0.1 to 0.4 cases per 100,000. Bimodal age distribution with peak between ages 15 to 25 and 36 to 46. There is no clear gender predisposition.

GENETICS: Studies suggest a genetic component. Various HLA antigens have been linked to both susceptibility (class II types DRB1*15 and DRB1*12) and prognosis (class I types B35 with self-limited disease, DR2 and DR5 with chronic disease), but results remain unverified.

RISK FACTORS: Infectious triggers are suspected to underlie the onset of AOSD in genetically susceptible hosts. Many patients have preceding exposures, and disease onset or relapse often follows a viral-like prodrome of pharyngitis, malaise, fever, and rash. Investigation of specific viral and bacterial organisms, however, is still unrevealing.

ETIOLOGY

Exact pathogenesis is unclear. Abnormal macrophage activation plays a role, given elevated levels of IL-1, IL-6, IL-18, tumor necrosis factor alpha (TNF-α), interferon gamma, migration inhibiting factor, and heme oxygenase-1 in serum of patients with AOSD. Recent studies have shown a higher amount of neutrophil extracellular trap (NET) molecules in the serum of patients with active AOSD compared with controls, and levels of these molecules decreased after treatment. Research is ongoing to evaluate the clinical implications of these results.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The "cardinal symptoms" of AOSD are fever, arthralgias/arthritis, and skin rash. This triad is seen in 75% to 95% of patients. Quotidian pattern fever usually occurs in late afternoon or early evening, with body temperature >102 °F (38.9 °C) lasting 2 to 4 hours before returning to normal. Up to 20% of patients have a "double quotidian" fever with a second spike in the early morning. Classic evanescent maculopapular rash is salmon-pink and nonpruritic, mainly affecting the trunk and proximal extremities. Koebner phenomenon is noted in up to 40% of patients. Visible rash may accompany fever and resolve when the patient is afebrile, making evaluation difficult. Arthralgias are nearly ubiquitous. Inflammatory joint involvement typically manifests as symmetric polyarthritis of larger joints. Progressive destructive arthritis affects up to half of patients. Other nonspecific symptoms include prodromal pharyngitis, lymphadenopathy, myalgias, hepatosplenomegaly, and serositis.

DIAGNOSIS

There is no pathognomonic finding in AOSD. Diagnosis depends on the recognition of a constellation of clinical and laboratory factors. It is a diagnosis of exclusion and requires rule-out of an extensive list of alternative infectious, neoplastic, and inflammatory etiologies.

DIFFERENTIAL DIAGNOSIS

See Fig. E1.

LABORATORY TESTS

Lab abnormalities include neutrophilic leukocytosis (WBC >12, >80% PMNs), markedly elevated inflammatory markers (ESR >50, CRP often >10× ULN). Normocytic anemia (Hg <10), thrombocytosis, hypoalbuminemia, and mild transaminitis can also be seen. Aldolase may be elevated with liver injury, but CPK levels are typically normal. Hyperferritinemia is a highly suggestive finding and levels >5 times upper limit of normal can be seen. Antinuclear antibodies and rheumatoid factor are negative.

IMAGING STUDIES

- Radiographs (Figs. E2 and E3): Early changes include soft tissue swelling, joint effusion, periarticular osteopenia; with later destructive arthropathy may see narrowed carpometacarpal and intercarpal joint spaces of wrist, eventually leading to ankylosis

CATEGORY	DISEASE	EVALUATION RECS
INFECTIOUS		
Bacterial	Septicemia, endocarditis, tuberculosis, brucellosis, yersinia, Lyme disease	Cultures, TTE, IGRA, PCR
Viral	Hepatitis, parvo B19, HIV, CMV, EBV, rubella, mumps, coxsackie, adenovirus	Serologies, PCR
Parasitic	Toxoplasmosis, parasitic abscess	
MALIGNANT		
Hematologic	Lymphoma, leukemia, angioblastic T-cell lymphoma, myeloproliferative disease, Castleman disease	Lymph node biopsy, bone marrow biopsy, PET/CT
Solid tumors	Colon, lung, kidney, paraneoplastic syndromes	
SYSTEMIC		
Rheumatologic	Systemic lupus erythematosus, rheumatoid arthritis, reactive arthritis, necrotizing or other vasculitides, poly-/dermato-myositis	Antibody testing, imaging, muscle biopsy
Autoinflammatory	Schnitzler's syndrome, Sweet syndrome, hemophagocytic lymphohistiocytosis, Kikuchi-Fujimoto disease, periodic fever syndromes (i.e., familial Mediterranean fever FMF, TNF receptor associated period syndrome [TRAPS], Cryopyrin associated periodic syndromes [CAPS], etc.)	Skin biopsy, bone marrow biopsy, family history, gene sequence analysis
Other	Drug hypersensitivity (i.e., drug rash with eosinophilia and systemic symptoms [DRESS]), sarcoidosis	CBC, ACE, biopsy

FIG. E1 Differential diagnosis of adult-onset Still disease. *ACE,* Angiotensin-converting enzyme; *CBC,* complete blood count; *CMV,* cytomegalovirus; *CT,* computed tomography; *EBV,* Epstein-Barr virus; *FMF,* familial Mediterranean fever; *HIV,* human immunodeficiency virus; *IGRA,* interferon gamma release assay; *PCR,* polymerase chain reaction; *PET,* positron-emission tomography; *TNF,* tumor necrosis factor; *TTE,* transthoracic echocardiogram.

FIG. E2 (A and B) Radiographs of wrists in a patient with adult-onset Still disease showing a narrowing of the carpometacarpal and intercarpal spaces and focal erosive alterations that have led to bone ankylosis in the left wrist. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

- CT and MRI studies: May show lymphadenopathy, organomegaly, early bone changes
- FDG PET/CT scans: Increased FDG uptake in spleen, bone marrow, and hyperplastic lymph nodes with concurrent decreased uptake in blood pool and liver

DIAGNOSTIC CRITERIA

Multiple diagnostic criteria have been proposed for evaluation of patients with suspected AOSD. Fautrel criteria are the most specific but require measurement of glycosylated ferritin, which is not readily available. The Yamaguchi criteria are more sensitive and widely used (Fig. E4).

DISPOSITION

Overall survival is good with 5-yr survival rates of 90% to 95%, but long-term therapy may be required to control symptoms or prevent recurrence. Patients follow one of three distinct clinical courses:

1. Self-limited/monophasic: Symptoms last <1 yr, then entirely remit.
2. Intermittent/relapsing: Recurrent flares over years of gradually more mild disease, alternating with periods of complete remission.
3. Chronic/progressive: Persistent primarily articular disease, with eventual erosive destruction leading to disability and need for arthroplasty.

Polyarthritis and large joint involvement with high ferritin level at onset of disease are poor prognosticators associated with progression to chronic disease.

Rx TREATMENT

ACUTE GENERAL Rx

Mild disease may be treated with full-dose NSAIDs alone, though less than a quarter of patients effectively respond to this. In most cases, glucocorticoids and/or other immunosuppressives are required. A treatment strategy for AOSD is illustrated in Fig. E5.

CHRONIC Rx

Immunomodulatory therapies are required for severe disease and persistent or recurrent symptoms during steroid taper. Oral and injectable methotrexate has been used for steroid-sparing effect, particularly for arthritis-predominant symptoms. IL-1 blockade (anakinra, canakinumab) is particularly beneficial for symptom resolution. More recently, anti-IL-6 agents (tocilizumab, sarilumab) and TNF inhibitors (etanercept, infliximab) have been used both alone and in combination with methotrexate, with efficacious results. Clinical response should be evaluated after 2 to 3 mo on therapy, and if poor response, should be switched to a biologic with different mechanism of action. Once prolonged remission is achieved, biologics may cautiously be tapered. Limited evidence exists for use of rituximab, abatacept, or IVIG in particularly severe or refractory disease.

TREATMENT SUMMARY

See Fig. E6.

PEARLS & CONSIDERATIONS

MACROPHAGE ACTIVATION SYNDROME

Reactive hemophagocytic lymphohistiocytosis (RHL), also known as macrophage activation syndrome (MAS), is reported in 12% to 17% of AOSD patients. The syndrome comprises uncontrolled inflammatory activation leading to phagocytosis of hematopoietic cells by macrophages, and mortality ranges from 10% to 22%. The clinical picture can be difficult to differentiate from flare of AOSD, but a few features are more closely correlated with MAS (i.e., hypofibrogenemia, leukopenia, thrombocytopenia, hypertriglyceridemia, and normalization of ESR all raise suspicion for MAS). Bone marrow aspiration is the gold standard for diagnosis, and initial treatment consists of pulse steroids, IVIG, and biologics (IL-1 or IL-6 blockade).

COMMENTS

- AOSD is a systemic illness comprising quotidian fever, evanescent rash, inflammatory polyarthritis, neutrophilic leukocytosis, and hyperferritinemia.
- Current treatment options include steroids, DMARDs, anti-IL-1 agents, anti-IL-6 agents, and TNF inhibitors.
- Macrophage activation syndrome is a rare but life-threatening complication of AOSD.

Akathisia

BASIC INFORMATION

DEFINITION

Akathisia is a movement disorder associated with an intense inner sense of subjective motor restlessness usually involving the lower extremities and leading to difficulty remaining still. In most cases the movement is repetitive and may involve crossing, uncrossing, and swinging of legs, or shifting weight from one foot to the other. Antipsychotic-related akathisia is most common and can be classified according to the time of onset in the course of antipsychotic treatment (acute, tardive, withdrawal, and chronic akathisia).

SYNONYMS

Acathisia
Restless Legs Syndrome

ICD-10CM CODES

G25.71 Drug-induced akathisia
- Neuroleptic induced acute akathisia
- Tardive akathisia
- Acathisia (drug induced)
- Akathisia (drug-induced) (treatment-induced)

DSM-5 CODE

333.99 Medication induced acute akathisia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Varies widely from 21% to 75%. Occurrence higher with first generation, or typical, antipsychotics, particularly high-potency agents such as haloperidol, than with atypical antipsychotics.

PREVALENCE: Varies from 20% to 35%. Reported prevalence rates vary between 5% and 36.8%.

PREDOMINANT SEX AND AGE: Akathisia occurs predominantly in younger patients. Incidence appears to decrease with age.

RISK FACTORS: Younger age when treated with antipsychotic medications, Parkinson disease, traumatic brain injury (TBI), encephalitides, and deficiencies of vitamin D or iron.

Akathisia usually occurs within first few days of treatment but also with dosage advancements or switch to a higher potency neuroleptic or withdrawal of an antiparkinsonian drug. Akathisia is more commonly associated with first generation antipsychotics. It occurs in patients taking second generation antipsychotics, although usually at lower rates.

GENETICS: Generally, akathisia is not considered a highly heritable condition, but a genetic predisposition to or family history of akathisia can confer some added risk. There is recent evidence of *PI4K2A* deficiency leading to intellectual disability, epilepsy, myoclonus, and an akathisia syndrome beginning in childhood as products of a consanguineous relationship.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients typically describe a subjective feeling of restlessness with the impulse to move and will objectively be seen pacing, rocking, and shifting position. Motor activity consists of complex, quasi-purposeful and repetitive movements. Milder cases present with subjective inner restlessness deep in the legs predominantly. Moderate cases are characterized by a tendency to rock back and forth from foot to foot accompanied by a coarse tremor or foot myoclonus. Severe akathisia patients have difficulty maintaining a position, often shuffling their feet when sitting and then getting up repeatedly and pacing. Akathisia is most severe when the patient cannot tolerate any position for more than a few moments. Acute cases usually last less than 6 mo. Chronic cases last for more than 6 mo after last dose increase. Dysphoria and subjective restlessness may be less marked in chronic cases, but dyskinesias are not uncommon. Pseudoakathisia, occurring mostly in men, is associated with motor signs such as fidgetiness without subjective restlessness complaints and with less dysphoria. Tardive akathisia can occur in situations with delayed onset in the setting of a tardive dyskinesia/tardive syndrome. Rebound withdrawal akathisia refers to onsets within 6 wk of discontinuation or dose decrease of an antipsychotic.
- To assess the severity of akathisia, tools such as the Barnes Akathisia Rating Scale (BARS), the Hillside Akathisia Scale, or the Drug-Induced Extrapyramidal Symptoms Scale are used.
- The inner restlessness of patients with akathisia can lead to extreme anxiety and depressed mood. In chronic cases, akathisia has also been associated with a high risk of self-harm or suicidal behavior. A careful evaluation for depression, anxiety, and suicidal ideation is necessary.
- Prognosis is good if the condition is recognized and the offending drug is discontinued. If the condition is left untreated, it can become disabling with high morbidity and can also lead to suicidal ideation. Suicidal, aggressive, and violent behaviors have been reported.
- Use of the term *akathisia* is often reserved for medication-related and antipsychotic-induced akathisia, although the broad definition of akathisia includes the inner and motor restlessness observed in patients with idiopathic Parkinson disease, postencephalitic parkinsonism, and restless legs syndrome.

ETIOLOGY

- Pathophysiology is poorly understood, though a complex mixture of neurotransmitter effects is suspected. Given its association with extrapyramidal side effects such as dystonia and parkinsonism, akathisia is suspected to be secondary to antipsychotic-related dopamine type 2 receptor downregulation and acetylcholine upregulation in basal ganglia regions. Central adrenergic and GABAergic mechanisms likely play a role, and neurosteroids have been implicated. Serotoninergic drugs can exacerbate akathisia. The pathophysiologies of acute akathisia and tardive akathisia may differ in that neuroleptics worsen the former and tend to be less distressing in the latter.
- In addition to antipsychotics, akathisia has been associated with calcium channel blockers, antiemetics, antimigraine agents, antivertigo drugs, antidepressants (selective serotonin reuptake inhibitors and serotonin-norepinephrine reuptake inhibitors), and sedatives used in anesthesia. Akathisia has also been noted to occur following abuse of cocaine and during withdrawal from alcohol, benzodiazepines, barbiturates, or opiates.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Akathisia is often underdiagnosed because symptoms often mimic osr overlap other psychiatric disorders such as psychosis, mania, attention deficit hyperactivity disorder (ADHD), or agitated depression. Agitation is transdiagnostic, occurring in psychoses, affective disorders, anxiety disorders, restless legs syndrome, insomnia, and drug withdrawal. Thus it is important to obtain a complete medical history and rule out other psychiatric disorders (Table 1).

WORKUP

The Barnes Akathisia Rating Scale or another akathisia scale may be used to assess patients with akathisia. However, most clinicians will rely on clinical observation.

LABORATORY TESTS

There are no discriminatory laboratory tests involved in the diagnosis of akathisia.

TABLE 1 Akathisia Differential Diagnoses

- Agitation secondary to multiple psychiatric conditions
- Attention deficit hyperactivity disorder
- Antipsychotic-induced dysphoria
- Restless legs syndrome
- Tardive dyskinesia
- Drug and alcohol withdrawal
- Insomnia
- Neuropsychiatric disorders including catatonic excitement, TBI, delirium, encephalitides, hypoglycemia, CNS autoimmune diseases
- Neurodegenerative disorders including dementia, Parkinson disease, Huntington disease

CNS, Central nervous system; *TBI,* traumatic brain injury.

IMAGING STUDIES

There are no discriminatory radiographic tests involved in the diagnosis of akathisia.

Rx TREATMENT

The most reliable treatment for acute akathisia is the reduction or the withdrawal of antipsychotic medication. However, this is often not possible because of the patient's mental condition. Use of adjunctive medications that dampen akathisia can be helpful (Table 2). Other agents that have been investigated include ritanserin, piracetam, valproic acid, trazodone, and tricyclic antidepressants. The treatment of tardive akathisia has been unsatisfactory, and more research is needed.

COMPLEMENTARY & ALTERNATIVE MEDICINE

If anxiety and stress are major contributors to subjective complaints, mind-body approaches such as relaxation breathing, meditation, or progressive muscle relaxation can be tried.

DISPOSITION

Psychiatric and neurologic outpatient care

REFERRAL

Once the diagnosis of akathisia is made, the patient should be referred to a neurologist and a psychiatrist. Making decisions on the medications can be challenging because most patients rely on antipsychotics for their mental health condition.

PEARLS & CONSIDERATIONS

- It may be difficult to determine whether a patient is experiencing akathisia or anxiety or agitation.
- Early identification and management are important as akathisia may be associated with treatment nonadherence.
- Antipsychotic-induced akathisia may be managed by reducing the dose of the offending agent or switching to an alternative antipsychotic agent.
- Beta-blockers such as propranolol and benzodiazepines have historically been used, although research is limited.
- Anticholinergic agents such as benztropine may be used if concomitant parkinsonism is present.

PREVENTION

As a medication side effect, prevention is the best approach to minimizing akathisia. Knowledge of past medication effects is essential. Strict adherence to standard titration and dose schedules, recognition of drug-drug interaction challenges, and preference for second generation antipsychotic medications all aid in akathisia prevention.

PATIENT & FAMILY EDUCATION

Patient education is essential. It should include open discussion of benefits vs. risks. Time of onset, duration of symptoms, other treatment options, and need to call parameters are important topic areas. Clear discussion of the therapeutic strategies that can be helpful if akathisia emerges should be discussed. Establishment of a trusting relationship can modify the anxiety and stress that can exacerbate akathisia.

RELATED TOPICS

Restless Legs Syndrome (Related Key Topic)

AUTHOR: **Gregory L. Fricchione, MD**

TABLE 2 Adjunctive Pharmacotherapies for Akathisia

- Beta-adrenergic antagonists (e.g., propranolol: Initiate at low doses 10 mg TID with titration up every few days to a maximum of 90-120 mg/day)
- Benzodiazepines (e.g., lorazepam 1.5-3 mg/day in divided doses or clonazepam 0.5 mg/day)
- Anticholinergics (e.g., benztropine 2 mg/day if other EPS in addition to akathisia)
- 5-HT2A antagonist (e.g., cyproheptadine 16 mg/day)
- Alpha-2-adrenergic agonists (e.g., clonidine 0.2-0.8 mg/day)
- Noradrenergic and specific serotonergic antidepressant (e.g., mirtazapine 7.5-15 mg/day; do not use higher dose that increases noradrenergic action)
- NMDA antagonist/indirect dopamine agonist (e.g., amantadine, 100 mg BID-TID)

BID, Twice a day; *NMDA,* N-methyl-d-aspartate; *TID,* three times a day.

Alcohol Use Disorder ALG PTG

BASIC INFORMATION

DEFINITION

Moderate drinking has been defined as two standard drinks (e.g., 12 oz of beer) per day and one drink per day for women and persons older than 65 yr. Although not generally included under the alcoholism topic, hazardous or at-risk drinking should also be considered. For men, *at-risk drinking* is defined as more than 14 drinks/wk or more than 4 drinks/occasion. For women, at-risk drinking is defined as approximately half that given for men.

The American Psychiatric Association defines diagnostic criteria for *alcohol withdrawal* as follows:

A. Cessation of (or reduction in) alcohol use that has been heavy and prolonged.
B. Two (or more) of the following, developing within several hours to a few days after criterion A:
   1. Autonomic hyperactivity (e.g., sweating or pulse rate >100 beats/min)
   2. Increased hand tremor
   3. Insomnia
   4. Nausea and vomiting
   5. Transient visual, tactile, or auditory hallucinations or illusions
   6. Psychomotor agitation
   7. Anxiety
   8. Grand mal seizures
C. The symptoms in criterion B cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

The symptoms are not attributable to a general medical condition and are not better accounted for by another mental disorder.

SYNONYMS

Alcohol dependence syndrome
Substance abuse
Alcohol withdrawal syndrome
Alcoholism

ICD-10CM CODES

F10	Mental and behavioral disorders due to use of alcohol
F10.1	Mental and behavioral disorders due to use of alcohol: harmful use
F10.2	Mental and behavioral disorders due to use of alcohol: dependence syndrome
F10.3	Mental and behavioral disorders due to use of alcohol: withdrawal state
F10.4	Mental and behavioral disorders due to use of alcohol: withdrawal state with delirium
F10.5	Mental and behavioral disorders due to use of alcohol: psychotic disorder
F10.6	Mental and behavioral disorders due to use of alcohol: amnesic syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- The clinical history suggests alcohol problems in 15% to 20% of patients in primary care and hospitalized patients. In the U.S., alcohol use disorder generates nearly $223 billion in annual economic costs. An estimated 14% of adults in the U.S. have alcohol dependence. Alcohol accounts for 6.8% of age-standardized deaths in men and 2.2% in women.
- 20% achieve abstinence without help; 70% achieve sobriety for 1 yr.

PREVALENCE (IN U.S.): 7% of population ≥18 yr

PREDOMINANT SEX:

- Lifetime risk for males 8% to 10%
- Lifetime risk for females 3% to 5%

PEAK INCIDENCE: 20 to 40 yr. The most common age range for initial treatment of alcohol dependence is 35 to 45 yr. However, the peak period for meeting alcohol dependence criteria is ≥10 yr earlier.

GENETICS: More common with a family history of alcoholism and in patients of Irish, Scandinavian, and Native American descent

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Recurring minor trauma
- Gastrointestinal bleeding from gastritis and/or varices
- Pancreatitis (acute and chronic)
- Liver disease
- Odor of alcohol on breath
- Tremulousness
- Tachycardia
- Peripheral neuropathy
- Recent memory loss

ETIOLOGY

- Social and genetic factors important
- Risk factors:
  1. Broken homes
  2. Unemployment
  3. Divorce
  4. Recurrent depression
  5. Addiction to another substance, including tobacco
  6. Working long hours (≥55 hours/week)

DIAGNOSIS

WORKUP

- The USPSTF recommends that clinicians screen adults 18 yr and older for alcohol misuse and provide persons engaged in risky or hazardous drinking with brief behavioral counseling interventions to reduce alcohol misuse. Several screening tests (CAGE [Table 1], TWEAK, CRAFFT, AUDIT-C [Table 2]) are available. The four-item CAGE (feeling need to **C**ut down, **A**nnoyed by criticism, **G**uilty about drinking, and need for an **E**ye-opener in the morning) is the most popular screening test in primary care. A positive response should lead to further questioning. The sensitivity of the CAGE ranges from 43% to 94% and its specificity ranges from 70% to 97%. The five-item TWEAK scale (**T**olerance, **W**orry, **E**ye-openers, **A**mnesia, [**K**] cut down) and the TACE questionnaire (**T**olerance, **A**nnoyance, **C**ut down, **E**ye-opener) are designed to screen pregnant women for alcohol misuse. They detect lower levels of alcohol consumption that may pose risks during pregnancy. The CRAFFT questionnaire (riding in **C**ar with someone who was drinking, using alcohol to **R**elax, using alcohol while **A**lone, **F**orgetfulness, criticism from **F**riends and **F**amily, **T**rouble) is useful as a screening tool for adolescents. Its sensitivity is 92% and specificity 64% for alcohol use disorder. Single-question screening about alcohol consumption in a day ("When was the last time you had more than X drinks in a day?" [where X is 5 for men and 4 for women]) with the threshold set at "in the past 3 months" is 85% sensitive and 70% specific in men and 82% and 70% in women for unhealthy alcohol use. The 3-question AUDIT-C is a shorter form of the 10-item AUDIT, and the questions center on the quantity and frequency of alcohol use. It asks how often someone has had a drink containing alcohol, how many standard drinks containing alcohol one consumes on a typical day when one is drinking, and how often one has six or more drinks on one occasion. Scoring ranges from 0 to 4 on each question with a total score range of 0 to 12. A total score of 3 or higher for women and 4 or higher for men indicates alcohol use disorder and need for further assessment. Its sensitivity ranges from 85% in Hispanic women to 95% in white men.
- Laboratory evaluation (see below).

LABORATORY TESTS

Lab tests alone do not accurately detect alcohol problems but can help identify medical complications related to alcohol use, such as pancreatitis or cirrhosis.

TABLE 1 CAGE Questionnaire for Alcohol Problems Screening[a]

C	Have you felt the need to **C**ut down on your drinking?
A	Have people **A**nnoyed you by criticizing your drinking?
G	Have you ever felt bad or **G**uilty about your drinking?
E	Have you had a drink first thing in the morning to steady your nerves or to get rid of a hangover (i.e., an "**E**ye opener")?

From Stern TA et al: *Massachusetts General Hospital handbook of general hospital psychiatry,* ed 7, Philadelphia, 2018, Elsevier.

TABLE 2 AUDIT-C Questionnaire for Alcohol Problems Screening[a]

Question	Score
How often did you have a drink containing alcohol in the past year?	Never (0 points) Monthly or less (1 point) 2-4 times per month (2 points) 2-3 times per week (3 points) >4 times per week (4 points)

[a]AUDIT-C is scored 0-12, with score >4 (men) and >3 (women) considered positive for problematic drinking.

From Stern TA et al: *Massachusetts General Hospital handbook of general hospital psychiatry,* ed 7, Philadelphia, 2018, Elsevier.

- Gamma-glutamyltransferase (GGTP), generally elevated
- Liver transaminases (alanine aminotransferase [ALT], aspartate aminotransferase [AST]), often elevated, may be normal or low in advanced liver disease.
- Low albumin level, hypophosphatemia, hypomagnesemia from malnutrition
- Complete blood count (CBC) reveals elevated mean corpuscular volume from toxic effect of alcohol on erythrocyte development in nutritional deficiencies.
- Stool for occult blood may be positive as a result of gastritis or variceal bleeding.
- RBC folate, vitamin B_{12} level, vitamin B_6, vitamin B_1 level

IMAGING STUDIES

Indicated only with a history of trauma. CT or ultrasound of abdomen may reveal fatty liver or cirrhosis in advanced stages.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Twelve-step facilitation, cognitive behavioral therapy, and motivational enhancement therapy improve the chances of recovery in patients with alcohol use disorder and dependence.
- Depression, if present, should be treated at same time alcohol is withdrawn.

ACUTE GENERAL Rx

Alcohol withdrawal syndrome (AWS) occurs when a person stops ingesting alcohol after prolonged consumption. It can result in four possible clinical patterns depending on the severity of the patient's alcohol use and the time from the patient's previous alcohol ingestion. Blood ethanol level decreases by ~20 mg/dl/hr in a normal person. Although discussed separately, these withdrawal states blend together in real life. Table 3 summarizes medications for the treatment of alcohol dependence. The cornerstone of treatment for alcohol withdrawal syndrome is the use of benzodiazepines.

- **Tremulous state** (early alcohol withdrawal, "impending DTs," "shakes," "jitters").
  1. Time interval: usually occurs 6 to 8 hr after the last drink or 12 to 48 hr after reduction of alcohol intake; becomes most pronounced at 24 to 36 hr.
  2. Manifestation: tremors, mild agitation, insomnia, tachycardia; symptoms are relieved by alcohol.
  3. Detoxification can be in the outpatient (ambulatory) or inpatient setting. Candidates for outpatient detoxification should have a reasonable support system (e.g., reliable contact person) who can monitor progress and lack of any significant comorbid conditions (e.g., suicide risk, seizure disorder, coexisting benzodiazepine dependence, prior unsuccessful outpatient detoxification, pregnancy, cirrhosis) or risk factors for severe withdrawal (age >40 yr, drinking >100 g of ethanol daily [e.g., 1 pint of liquor or eight 12-oz cans of beer, random blood alcohol concentration >200 mg/dl]).
  4. Inpatient treatment:
     a. Admit to medical floor (private room); monitor vital signs q4h; institute seizure precautions; maintain adequate sedation.
     b. Administer lorazepam as follows:
        (1) Day 1: 2 mg PO q4h while awake and not lethargic.
        (2) Day 2: 1 mg PO q4h while awake and not lethargic.
        (3) Day 3: 0.5 mg PO q4h while awake and not lethargic.
        (4) NOTE: Hold sedation for lethargy or abnormal vital or neurologic signs. The preceding doses are only guidelines; it is best to titrate the dose case by case.
     c. In patients with mild to moderate withdrawal and without history of seizures, individualized benzodiazepine administration (rather than a fixed-dose regimen) results in lower benzodiazepine administration and avoids unnecessary sedation. The Clinical Institute Withdrawal Assessment Scale for Alcohol, Revised (CIWA-Ar) scale (Box 1) can be used to measure the severity of alcohol withdrawal. It consists of 10 items: nausea; tremor; autonomic hyperactivity; anxiety; agitation; tactile, visual, and auditory disturbances; headache; and disorientation. Each item is assigned a score from 0 to 7. For example, in the "agitation" category 0 indicates normal activity, and 7 indicates that the patient constantly thrashes about. For the category of "tremor," 0 indicates that tremor is not present and 7 that tremor is severe, even with arms not extended. The maximum total score is 67. Patients with mild AWS symptoms (CIWA-Ar score <8)

TABLE 3 Medications for the Treatment of Alcohol Dependence*

Medication	Dose and Route	Frequency	Effects	Major Common Adverse Effects
Alcohol Withdrawal				
		Benzodiazepines†		
Chlordiazepoxide*	25-100 mg, PO/IV/IM†	Every 4-6 hr	Decreased severity of withdrawal; stabilization of vital signs; prevention of seizures and delirium tremens	Confusion, oversedation, respiratory depression
Diazepam‡	5-10 mg, PO/IV/IM†	Every 6-8 hr		
Oxazepam‡	15-30 mg, PO†	Every 6-8 hr		
Lorazepam‡	1-4 mg, PO/IV/IM†	Every 4-8 hr		
		β-Blockers		
Atenolol	25-50 mg, PO	Once a day	Improvement in vital signs	Bradycardia, hypotension
Propranolol	10-40 mg, PO	Every 6-8 hr	Reduction in craving	
		α-Agonists		
Clonidine	0.1-0.2 mg, PO	Every 6 hr	Decreased withdrawal symptoms	Hypotension, fatigue
		Antiepileptics		
Carbamazepine	200 mg, PO	Every 6-8 hr	Decreased severity of withdrawal; prevention of seizures	Dizziness, fatigue, red blood cell abnormalities
		Prevention of Relapse		
Disulfiram‡	125-500 mg, PO	Daily	Decreased alcohol use among those who relapse	Disulfiram-alcohol reaction, rash, drowsiness, peripheral neuropathy
Naltrexone‡	50 mg, PO	Daily	Increased abstinence, decreased drinking days	Nausea, abdominal pain, myalgias-arthralgias
	380 mg, IM	Every 4 wk		
Acamprosate‡	666 mg, PO	Three times a day	Increased abstinence	Diarrhea

*Most commonly used medications listed.
†Currently approved by U.S. Food and Drug Administration for the indication noted.
‡Dose and routes given for standard fixed-dose regimens, which include dose tapers over time.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

can be monitored on an outpatient basis. Benzodiazepines are beneficial for most patients with a CIWA-AR score ≥8 and are strongly recommended in patients with substantial withdrawal symptoms (CIWA-Ar score >12). Patients with CIWA-Ar score of ≥15 should be admitted to detox unit. In-patient treatment is also recommended for patients with history of withdrawal seizures and for those with suicidal ideation and significant comorbidities.

d. Beta-adrenergic blockers: Beta-blockers are useful for controlling blood pressure and tachyarrhythmias. However, they do not prevent progression to more serious symptoms of withdrawal and, if used, should not be administered alone but in conjunction with benzodiazepines. Beta-blockers should be avoided in patients with contraindications to their use (e.g., bronchospasm, bradycardia, or severe congestive heart failure). Centrally acting alpha-adrenergic agonists such as clonidine ameliorate symptoms in patients with mild to moderate withdrawal but do not reduce delirium or seizures.

e. Vitamin replacement: Thiamine 100 mg IV or IM for at least 5 days plus oral multivitamins. The IV administration of glucose can precipitate Wernicke encephalopathy in alcoholics with thiamine deficiency; therefore thiamine administration should precede IV dextrose.

f. Hydration PO or IV (high-caloric solution): If IV, glucose with Na+, K+, Mg2+, and phosphate replacement prn.

g. Laboratory studies:
   (1) CBC, platelet count, INR.
   (2) Electrolytes, glucose, blood urea nitrogen, creatinine.
   (3) GGTP, ALT, AST.
   (4) Phosphorus and magnesium.
   (5) Serum vitamin B_{12} and folic acid (if megaloblastic features in blood smear).

h. Diagnostic imaging: Generally not necessary; if subdural hematoma is suspected (evidence of trauma, persistent lethargy), a CT scan should be ordered.

i. Social rehabilitation: Group therapy such as Alcoholics Anonymous; identification and treatment of social and family problems should be initiated during the patient's hospital stay.

- **Alcoholic hallucinosis:**
  1. Manifestations: Hallucinations usually are auditory, but hallucinations occasionally are visual, tactile, or olfactory; usually there is no clouding of sensorium as in delirium (clinical presentation may be mistaken for an acute schizophrenic episode). Disordered perceptions become most pronounced after 24 to 36 hr of abstinence.
  2. Treatment: Same as for DTs (see "Withdrawal seizures").

- **Withdrawal seizures ("rum fits"):**
  1. Time interval: Usually occurs 7 to 30 hr after cessation of drinking, with a peak incidence between 13 and 24 hr.
  2. Manifestations: Generalized convulsions with loss of consciousness; focal signs are usually absent; consider further investigation with CT scan of head and electroencephalography if clearly indicated (e.g., presence of focal neurologic deficits, prolonged postictal confusion state). In addition, in a febrile patient who is having a seizure or altered mental state, a lumbar puncture is necessary.
  3. Treatment:
     a. Diazepam 2.5 mg/min IV until seizure is controlled (check for respiratory depression or hypotension) may be beneficial for prolonged seizure activity; IV lorazepam 1 to 2 mg q2h can be used in place of diazepam. Withdrawal seizures generally are self-limited and treatment is not required; the use of phenytoin or other anticonvulsants for short-term treatment of alcohol withdrawal seizures is not recommended.
     b. Thiamine 100 mg IV, followed by IV dextrose, should also be administered.
     c. Electrolyte imbalances (increased Mg^{2+}, decreased K^+, increased or decreased Na^+, decreased PO_4^{3-}) that may exacerbate seizures should be corrected.

BOX 1 Alcohol Withdrawal Assessment Scoring Guidelines (Revised Clinical Institute Withdrawal Assessment for Alcohol Scale)

Nausea and Vomiting (0-7)
0, none; 1, mild nausea with no vomiting; 4, intermittent nausea; 7, constant nausea, frequent dry heaves and vomiting

Tremor (0-7)
0, no tremor; 1, not visible, but can be felt fingertip to fingertip; 4, moderate, with patient's arms extended; 7, severe, even with arms not extended

Paroxysmal Sweats (0-7)
0, no sweats; 1, barely perceptible sweating, palms moist; 4, beads of sweat obvious on forehead; 7, drenching sweats

Anxiety (0-7)
0, no anxiety, patient at ease; 1, mildly anxious; 4, moderately anxious or guarded, so anxiety is inferred; 7, equivalent to acute panic states seen in severe delirium or acute schizophrenic reactions

Agitation (0-7)
0, normal activity; 1, somewhat more than normal activity; 4, moderately fidgety and restless; 7, pacing back and forth during, or constantly thrashing about

Tactile Disturbances (0-7)
Ask, "Have you experienced any itching, pins and needles sensation, burning or numbness, or a feeling of bugs crawling on or under your skin?"
0, none; 1, very mild itching, pins and needles, burning, or numbness; 2, mild itching, pins and needles, burning, or numbness; 3, moderate itching, pins and needles, burning, or numbness; 4, moderately severe tactile hallucinations; 5, severe hallucinations; 6, extremely severe hallucinations; 7, continuous hallucinations

Auditory Disturbances (0-7)
Ask, "Are you more aware of sounds around you? Are they harsh? Do they startle you? Do you hear anything that disturbs you or that you know isn't there?"
0, not present; 1, very mild harshness or ability to startle; 2, mild harshness or ability to startle; 3, moderate harshness or ability to startle; 4, moderate hallucinations; 5, severe hallucinations; 6, extremely severe hallucinations; 7, continuous hallucinations

Visual Disturbances (0-7)
Ask, "Does the light appear to be too bright? Is its color different than normal? Does it hurt your eyes? Are you seeing anything that disturbs you?"
0, not present; 1, very mild sensitivity to light; 2, mild sensitivity; 3, moderate sensitivity; 4, moderate hallucinations; 5, severe hallucinations; 6, extremely severe hallucinations; 7, continuous hallucinations

Headache (0-7)
0, not present; 1, very mild; 2, mild; 3, moderate; 4, moderately severe; 5, severe; 6, very severe; 7, extremely severe

Orientation and Clouding of Sensorium (0-4)
Ask, "What day is this? Where are you? Who am I?"
0, oriented; 1, cannot do serial additions or is uncertain about date; 2, disoriented to date by no more than 2 calendar days; 3, disoriented to date by more than 2 calendar days; 4, disoriented to place and/or person

Total Score
0 to 9: absent or minimal withdrawal
10 to 19: mild to moderate withdrawal
More than 20: severe withdrawal

From Sullivan JT et al: Assessment of alcohol withdrawal: the revised clinical institute withdrawal assessment for alcohol scale (CIWA-Ar). *Br J Addict* 84:1353-1357, 1989.

- **DTs:**
  1. Time interval: Variable; usually occurs within 1 wk after reduction or cessation of heavy alcohol intake and persists for 1 to 3 days. Peak incidence is 72 hr and 96 hr after the cessation of alcohol consumption.
  2. Manifestations: Profound confusion, tremors, vivid visual and tactile hallucinations, autonomic hyperactivity; this is the most serious clinical presentation of alcohol withdrawal (mortality rate is approximately 15% in untreated patients).
  3. Treatment:
     a. Admission to a detoxification unit where patient can be observed closely.
     b. Vital signs q30min (neurologic signs, if necessary).
     c. Use of lateral decubitus or prone position if restraints are necessary.
     d. NPO: Nasogastric tube for abdominal distention may be necessary but should not be routinely used.
     e. Laboratory studies: Same as for early alcohol withdrawal.
     f. Vigorous hydration (4 to 6 L/day): IV with glucose (Na^+, K^+, PO_4^{3-} and Mg^{2+} replacement [if patient has hypophosphatemia or hypomagnesemia]).
     g. Vitamins: Thiamine 100 mg IV qd. The initial dose of thiamine should precede the administration of IV dextrose; multivitamins (may be added to the hydrating solution).
     h. Sedation: Control of agitation should be achieved with rapid-acting sedative-hypnotic agents in adequate doses to maintain light somnolence for the duration of delirium.
        (1) Initially: Lorazepam 2 to 5 mg IM/IV repeated prn.
        (2) Maintenance (individualized dosage): Chlordiazepoxide, 50 to 100 mg PO q4-6h, lorazepam 2 mg PO q4h, or diazepam 5 to 10 mg PO tid; withhold doses or decrease subsequent doses if signs of oversedation are apparent.
        (3) Midazolam is also effective for managing DTs. Its rapid onset (sedation within 2 to 4 min of IV injection) and short duration of action (approximately 30 min) make it an ideal agent for titration in continuous infusion.
     i. Treatment of seizures (as previously described).
     j. Diagnosis and treatment of concomitant medical, surgical, or psychiatric conditions.

CHRONIC Rx

- See "Referral."
- Pharmacotherapies for alcoholism include:
  1. Acamprosate is a synthetic compound with a chemical structure similar to the neurotransmitter gamma-aminobutyric acid and the amino acid neuromodulator taurine. Its mechanism of action is not completely understood. It is indicated for the maintenance of abstinence from alcohol in patients with alcohol dependence who are abstinent at treatment initiation. It should be used only as part of a comprehensive psychosocial treatment program. It does not cause a disulfiram-like reaction as a result of ethanol ingestion. Dose is two 333-mg tablets tid. Treatment should be initiated as soon as possible after the period of alcohol withdrawal, when the patient has achieved abstinence, and should be maintained if the patient relapses. Avoid acamprosate if severe renal impairment is present.
  2. The long-acting opiate antagonist naltrexone inhibits the rewarding effects of alcohol. The starting dose is 25 mg/day, increased to 50 mg PO qd after 1 wk. An extended-release, once-monthly injection of naltrexone is also available and can be used along with psychosocial support to maintain alcohol abstinence. In patients with opioid dependence, naltrexone can precipitate acute withdrawal syndrome and should not be used at least 7 days from last opioid use. There are no established guidelines on the appropriate length of naltrexone treatment for alcohol dependence. One study recommends at least 3 mo of treatment. Avoid naltrexone if acute hepatitis, hepatic failure, or ongoing opioid use is present.
  3. Topiramate or gabapentin can be offered as second line drugs; to patients with moderate to severe alcohol use disorder topiramate might be preferable.
  4. Disulfiram (Antabuse): Dosage is 500 mg max qd for 1 to 2 wk, then 125 to 500 mg qd. It interferes with the metabolism of alcohol by inhibiting aldehyde dehydrogenase, causing an accumulation of acetaldehyde. It produces unpleasant symptoms (nausea, flushing, elevated blood pressure, headache, weakness) when alcohol is ingested. It is an older drug that is now rarely used.
  5. Avoid pharmacological treatments in pregnant or breastfeeding women.

DISPOSITION

See "Referral."

REFERRAL

- To Alcoholics Anonymous or Adult Children of Alcoholics
- Family members to Al-Anon or Al-A-Teen
- Many cities have Salvation Army Adult Rehabilitation centers; all patients accepted, regardless of ability to pay

PEARLS & CONSIDERATIONS

COMMENTS

- Relative indications for inpatient alcohol detoxification are as follows: history of DTs or withdrawal seizures, severe withdrawal symptoms, concomitant psychiatric or medical illness, pregnancy, multiple previous detoxifications, recent high levels of alcohol consumption, and lack of reliable support network.
- Detoxification is not a stand-alone treatment but should serve as a bridge to a formal treatment program for alcohol dependence.
- The cure rate for alcoholism is highly disappointing, regardless of the modality. Only those who want to be helped will be helped. An effective strategy for the primary care physician is a prominently displayed sign in the office that states, "If you think you consume too many alcoholic beverages, please discuss it with me." Those who do open up the discussion can be given the facts in a nonjudgmental way and often can be helped. All too often problem drinkers lie on the questionnaire until they face a life-threatening health issue—and even then denial often reigns supreme.
- In a recent clinical trial, patients receiving medical management with naltrexone (100 mg/day), combined behavioral intervention (CBI), or both fared better on drinking outcomes, whereas acamprosate showed no evidence of efficacy, with or without CBI. No combination produced better efficacy than naltrexone or CBI alone in the presence of medical management.

Alcoholic Hepatitis PTG ALG

BASIC INFORMATION

DEFINITION

Alcoholic hepatitis (AH) is a severe, progressive, inflammatory, and cholestatic liver disease occurring in patients with long-term heavy alcohol use (60 to 80 g/day in men and 20 to 40 g/day in women)

SYNONYM

AH

ICD-10CM CODES
K70.10 Alcoholic hepatitis without ascites
K70.9 Alcoholic liver disease, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Approximately 2 million people in the U.S. (about 1% of the population) are affected by alcoholic liver disease.
- Alcoholic hepatitis accounts for 0.8% of all admissions in the U.S.
- Typical presentation age: 40 to 50 yr. Majority occurs before age 60.
- Patients with alcoholic hepatitis typically drink more than 100 g of alcohol daily for two or more decades.

PREVALENCE: Approximately 25% to 30%
PREDOMINANT SEX AND AGE: The majority of patients are males. Males are two times as likely as women to abuse alcohol. However, women develop alcoholic hepatitis after a shorter time and smaller amount of alcoholic exposure than men.
GENETICS: No genetic predilection for any one race. In the U.S., however, there is increased incidence in minority groups.
RISK FACTORS: Drinking multiple alcohol types, drinking alcohol between meal times, poor nutrition, female gender, obesity, Hispanic ethnicity, long-term ingestion of >10 to 20 g/day of alcohol in women and >20 to 40 g/day in men

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Common presenting symptoms include:
- Rapid onset of jaundice
- Jaundice with duration <3 months
- Right upper quadrant pain
- Nausea/vomiting
- Malaise
- Low-grade fever
- Anorexia
- Abdominal distention/pain (due to ascites)
- Weight loss or malnourishment
- Proximal muscle wasting and weakness
- Complications of liver impairment (GI bleed; confusion, lethargy, ascites)

Findings on physical examination include:
- Jaundice and ascites
- Hepatomegaly, with tender liver on palpation
- Fever (first exclude other causes of fever, such as spontaneous bacterial peritonitis, urinary tract infection [UTI], pneumonia)
- Asterixis (a flapping tremor)
- Splenomegaly
- Tachycardia
- Hypotension
- Peripheral edema
- Abdominal distention with shifting dullness (ascites)
- Hepatic bruit
- With coexistent cirrhosis, look for:
  1. Gynecomastia
  2. Proximal muscles wasting
  3. Spider angiomata
  4. Altered hair distribution

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hepatitis B
- Hepatitis C
- Nonalcoholic steatohepatitis (NASH)
- Chronic pancreatitis
- Drug-induced liver injury
- Hemochromatosis
- Cholangitis

WORKUP

- The standard screening test for alcohol abuse is the Alcohol Use Disorders Identification Test (AUDIT).
- A thorough and detailed history is needed.
- Relevant questions may include:
  1. When patient started drinking
  2. Number of times patient drinks per day
  3. How many yr of regular/daily drinking
  4. Types of alcohol
  5. Home or bar drinking
  6. Rehabilitation for drinking
  7. Social problems (e.g., arrest for public intoxication or driving under the influence, marital discord due to alcoholism)

LABORATORY TESTS

The best biomarkers of harmful ethanol use are gamma glutamyltransferase (GGT), aspartate aminotransferase (AST), ethyl glucuronide (ETG), and phosphatidyl ethanol.
- Elevated transaminase (aspartate aminotransferase [AST] >45 U/L but <500 U/L; however, some patients may not have elevations in ALT, AST in early phases)
- AST:Alanine aminotransferase [ALT] ratio ≥2:1
- S-bilirubin >5 mg/dl
- Increased prothrombin time [PT]/international normalized ratio [INR]
- Elevated gamma glutamyltransferase (GGT)
- Carbohydrate-deficient transferrin (CDT) is a reliable marker for chronic alcoholism
- Elevated C-reactive protein
- Electrolyte disorder (hypokalemia, hypomagnesemia, low zinc, hypophosphatemia)
- Hypoalbuminemia
- Hyperferritinemia
- CBC (may reveal leukocytosis with bandemia or anemia or thrombocytopenia); mean corpuscular volume (MCV) may be elevated
- Screening tests to rule out other conditions include checking:
  1. Hepatitis B surface antigen (HBsAg), hepatitis B core antibody (HB_cAb) (IgM), hepatitis A antibody (IgM)
  2. Anti-hepatitis C antibody, hepatitis C ribonucleic acid (RNA)
  3. Ferritin-transferrin saturation
  4. Alpha-fetoprotein
  5. Alkaline phosphatase
- Laboratory criteria of severe alcoholic hepatitis are defined as
  1. Maddrey Discriminant Function (MDF) score >32, which is calculated as follows:
     MDF = 4.6 × prothrombin time – control prothrombin time + total bilirubin (mg/dl)
     OR
  2. Model for End-Stage Liver Disease (MELD) >21
     AND/OR
  3. Hepatic encephalopathy

There are other models for determining severity such as the Alcohol Hepatitis Histologic Score (AHHS) or for prognostication such as the MELD + Lille combination models.

IMAGING STUDIES

Ultrasonography is the preferred imaging study. The earliest histologic change in alcoholic liver disease is macrovesicular steatosis.

LIVER BIOPSY

- Liver biopsy is rarely needed.
- Useful to:
  1. Confirm the diagnosis.
  2. Evaluate the effect of coexisting disease.
  3. Rule out cirrhosis.
  4. Exclude other diagnoses (especially other causes of liver diseases, biliary obstruction, Budd-Chiari syndrome).
- Typical histologic findings include:
  1. Micro- or macrovesicular steatosis
  2. Hepatocyte injury (ballooning degeneration and focal hepatocyte necrosis)
  3. Mallory-Denk bodies (characteristic of alcoholic hepatitis)
  4. Perivenular fibrosis
  5. Portal and lobular inflammation with neutrophils or lymphocyte infiltration

TREATMENT

An algorithm for the management of patients with alcoholic hepatitis is described in Fig. 1. Treatment can be divided into three main components:
1. Lifestyle modifications
2. Nutritional support
3. Pharmacologic therapy

LIFESTYLE MODIFICATIONS

- Abstinence from alcohol (this improves both short- and long-term survival). Fig. E2 describes the effect of subsequent alcohol intake on 5-yr survival in patients with alcoholic hepatitis.
- Nonpharmacologic methods to promote abstinence include cognitive-behavioral therapy (CBT), Alcoholic Anonymous (AA) attendance, and motivational interviewing.
- Pharmacologic aids include using naltrexone, acamprosate, or baclofen.
- Monitor abstinence with breath test or urine drug screen (for use in past 3 days) or hair sample analysis for ethyl glucuronide (test alcohol intake within the last few months).
- Smoking cessation (to decrease oxidative stress).
- Treatment of substance abuse.

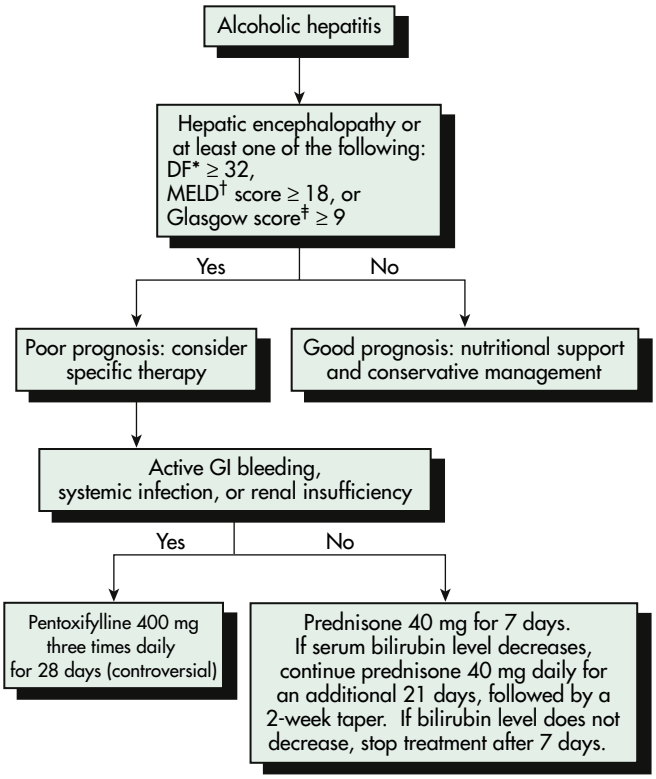

FIG. 1 Algorithm for the management of patients with alcoholic hepatitis. *The DF is calculated as follows: 4.6 (prothrombin time of patient – prothrombin time of control) + serum bilirubin level (in mg/dl). †The Model for End-Stage Liver Disease *(MELD)* score is based on the serum bilirubin level, INR, and serum creatinine level. ‡The Glasgow alcoholic hepatitis score is based on the patient's age, white blood cell count, blood urea nitrogen level, ratio of prothrombin time to a control value, and serum bilirubin level. *DF,* Discriminant function; *GI,* gastrointestinal. Online calculators for these various models are available at www.lillemodel.com. (Modified from Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.)

NUTRITIONAL SUPPORT

- Good nutrition is an essential part of treatment because many patients with alcoholic hepatitis have severe protein-calorie malnutrition as well as deficiencies of trace minerals and several vitamins.
- Nutritional support includes:
  1. Liberal vitamin supplementation (especially thiamine, folic acid, vitamin K)
  2. Mineral supplementation **(but not iron)**
  3. Calorie counting is essential. A high calorie intake (1.2 to 1.4 times the normal resting intake) may be required.
  4. Protein intake of 1.2 to 1.5 g/kg of ideal body weight per day will provide adequate support. **Exception: In patients with severe encephalopathy, protein restriction may be required.**
  5. Fluid management

PHARMACOLOGIC THERAPY

Severe alcoholic hepatitis may require treatment. Severity can be assessed by calculating the MELD score or MDF score or the Glasgow score.

- An MDF score ≥32 indicates significant or severe alcoholic hepatitis (30-day mortality of 50%).
- MELD score can easily be calculated (visit https://optn.transplant.hrsa.gov/resources/allocation-calculators/meld-calculator/). This score predicts short-term survival in patients with cirrhosis. A score >20 predicts increased short-term mortality.
- Glasgow score: Contains four variables (BUN, PT, WBC count, and bilirubin). A score ≥9 indicates increased mortality.

Indications for hospitalization include:

- MDF ≥32
- MELD >20
- Glasgow score >8
- Hepatic encephalopathy

Patients with severe alcoholic hepatitis may be treated with glucocorticosteroids (prednisolone 40 mg/day for 28 days with a 2-wk taper). Glucocorticosteroids reduce hepatic injury, suppress inflammation, and promote liver regeneration. However, not all studies have demonstrated consistent therapeutic benefits for steroids, even in high-risk patients. Prednisolone should be discontinued if bilirubin does not decrease by day 17. An alternative agent for patients with contraindications to corticosteroids is pentoxifylline. Pentoxifylline is not effective in patients who do not respond to prednisone, and data supporting its use is weak.

LIVER TRANSPLANTATION

- Usually reserved for patients with end-stage liver disease. Patients whose hepatitis is not responding to medical therapy have a 6-month survival rate of approximately 30%. Since most hepatitis deaths occur within 2 months, early liver transplantation is attractive and associated with higher than 80% survival at 3 yr.
- Patients with alcoholic hepatitis must be sober for at least 6 mo before they can be eligible for consideration for liver transplantation. However, transplantation candidates should not be based solely on 6 mo abstinence, and other factors, such as social support and need for rehabilitation, should be considered.

REFERRAL

Severe acute alcoholic hepatitis may require intensive care unit (ICU) care and referral to different subspecialists:

- GI/hepatology (for patients with evidence of GI hemorrhage)
- Nutritional services
- Nephrology (for acute renal failure, hepatorenal syndrome)
- Neurology (for change in mental status, seizures)
- Infectious disease (for fever/leukocytosis)

PEARLS & CONSIDERATIONS

COMMENTS

- Referral to substance abuse treatment programs may be helpful.
  1. Stress to patients that there are limited long-term drug treatments for alcoholic hepatitis.
  2. Maintaining good general nutrition is important.
  3. Advise patient about the risk of taking certain medications, especially acetaminophen.
- Periodic follow-up to monitor patient's response to check basic metabolic panel (BMP) and liver function tests (LFTs).
- Encourage alcohol abstinence. Abstinence improves long-term survival.
- If patient develops liver cirrhosis, check serum alpha-fetoprotein every 6 mo and liver ultrasound annually to rule out hepatocellular carcinoma.
- Vaccinate patient against hepatitis A and B viruses, pneumococci, influenza A virus, and routine adult vaccinations, if appropriate.

Aldosteronism (Hyperaldosteronism, Primary) PTG

BASIC INFORMATION

DEFINITION

Primary aldosteronism is a group of disorders distinguished by inappropriate, autonomous production of aldosterone resulting in renal sodium retention, plasma renin suppression, and secondary hypertension classically characterized by hypokalemia and metabolic alkalosis.

SYNONYMS

Hyperaldosteronism
Conn syndrome

ICD-10CM CODES

E26.01	Conn syndrome
E26.02	Glucocorticoid-remediable aldosteronism
E26.1	Secondary hyperaldosteronism
E26.9	Hyperaldosteronism, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: 5% to 13% of patients with hypertension; 11% to 23% of patients with resistant hypertension

GENETICS: Familial hyperaldosteronism is a subset of inheritable forms of hyperaldosteronism. It should be suspected in patients with any of the following:

- Onset of hypertension before age 21 years and a family history of hypertension
- A family history of primary aldosteronism
  A family history of stroke before age 40 yr

ETIOLOGY

- Bilateral idiopathic adrenal hyperplasia (60% to 70%)
- Unilateral aldosterone-producing adenoma (Conn syndrome) (30% to 40%)
- Unilateral adrenal hyperplasia (~2%)
- Familial hyperaldosteronism (<1%)
- Aldosterone-producing carcinoma (<0.1%)
- Ectopic production of aldosterone (<0.1%)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Generally asymptomatic
- Hypertension: Often resistant hypertension
- Spontaneous hypokalemia
- Family history of early-onset hypertension or cerebrovascular accident <40 yr

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diuretic use
- Hypokalemia from vomiting and/or diarrhea
- Renovascular hypertension
- Other endocrine neoplasm (pheochromocytoma, deoxycorticosterone-producing tumor, renin-secreting tumor)

WORKUP

Primary aldosteronism is characterized by suppressed plasma renin activity (PRA) and an elevated serum aldosterone level, usually exceeding 15 ng/dl. Fig. 1 provides guidance on when to consider testing for primary aldosteronism. Fig. 2 describes a diagnostic approach to patients with suspected primary aldosteronism. CT, MRI, and adrenal vein sampling (AVS) are used to distinguish unilateral from bilateral increased aldosterone secretion. This distinction will dictate treatment options since unilateral primary aldosteronism is treated by surgical resection rather than medically.

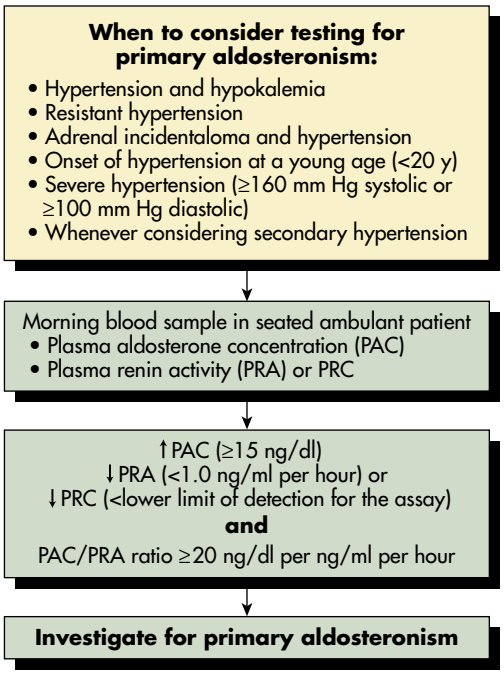

FIG. 1 Algorithm provides guidance on when to consider testing for primary aldosteronism and use of the ratio of plasma aldosterone concentration *(PAC)* to plasma renin activity *(PRA)* as a case-detection tool. *PRC,* Plasma renin concentration. (Melmed S et al (eds): *Williams textbook of endocrinology,* ed 13, Philadelphia, 2016, Elsevier.)

LABORATORY TESTS

Routine laboratory tests can be suggestive but are not diagnostic of primary aldosteronism. Common abnormalities are:

- Spontaneous hypokalemia (9% to 37% of cases) or severe hypokalemia while receiving conventional doses of diuretics
- Possible alkalosis and hypernatremia

IMAGING STUDIES

- Adrenal CT scan (Fig. E3) is preferred as adrenal adenomas have a high lipid content and are better visualized on CT scan.
- MRI may be used as an alternative.

TREATMENT

NONPHARMACOLOGIC THERAPY

Regular blood pressure monitoring, low-sodium diet, tobacco avoidance, maintenance of ideal body weight, and regular exercise

ACUTE GENERAL Rx

- Control of blood pressure and hypokalemia with spironolactone, eplerenone, or amiloride
- Surgery (unilateral adrenalectomy) for aldosterone-producing adenoma (APA) or unilateral adrenal hyperplasia (UAH)

CHRONIC Rx

A mineralocorticoid receptor antagonist, spironolactone (starting dose, 25 mg daily) or eplerenone (starting dose, 25 mg twice daily), is titrated upward until a serum potassium concentration target that is mid- to high-normal is achieved without the aid of potassium supplements. The dose is increased at 2-week intervals. Eplerenone causes less gynecomastia in men and less menstrual irregularities in women because of greater mineralocorticoid receptor selectivity. Amiloride (starting dose, 5 mg twice daily) may be used for patients intolerant of both spironolactone and eplerenone.

DISPOSITION

Treatment of primary aldosteronism with either mineralocorticoid receptor antagonism or unilateral adrenalectomy resolves hypokalemia, reduces blood pressure, and improves parameters of impaired cardiac and renal function.

Hypertension persists in 40% to 65% of patients after unilateral adrenalectomy. Patients more likely to experience complete resolution of hypertension are younger, take 2 or less antihypertensive agents preoperatively, have a short duration of hypertension, lack family history of hypertension, and/or have a higher PAC/PRA ratio.

REFERRAL

Referral to an experienced interventional radiologist for arteriovenous sampling. If lateralization occurs, surgical referral for unilateral adrenalectomy should proceed after confirmation of unilateral APA, UAH, or carcinoma.

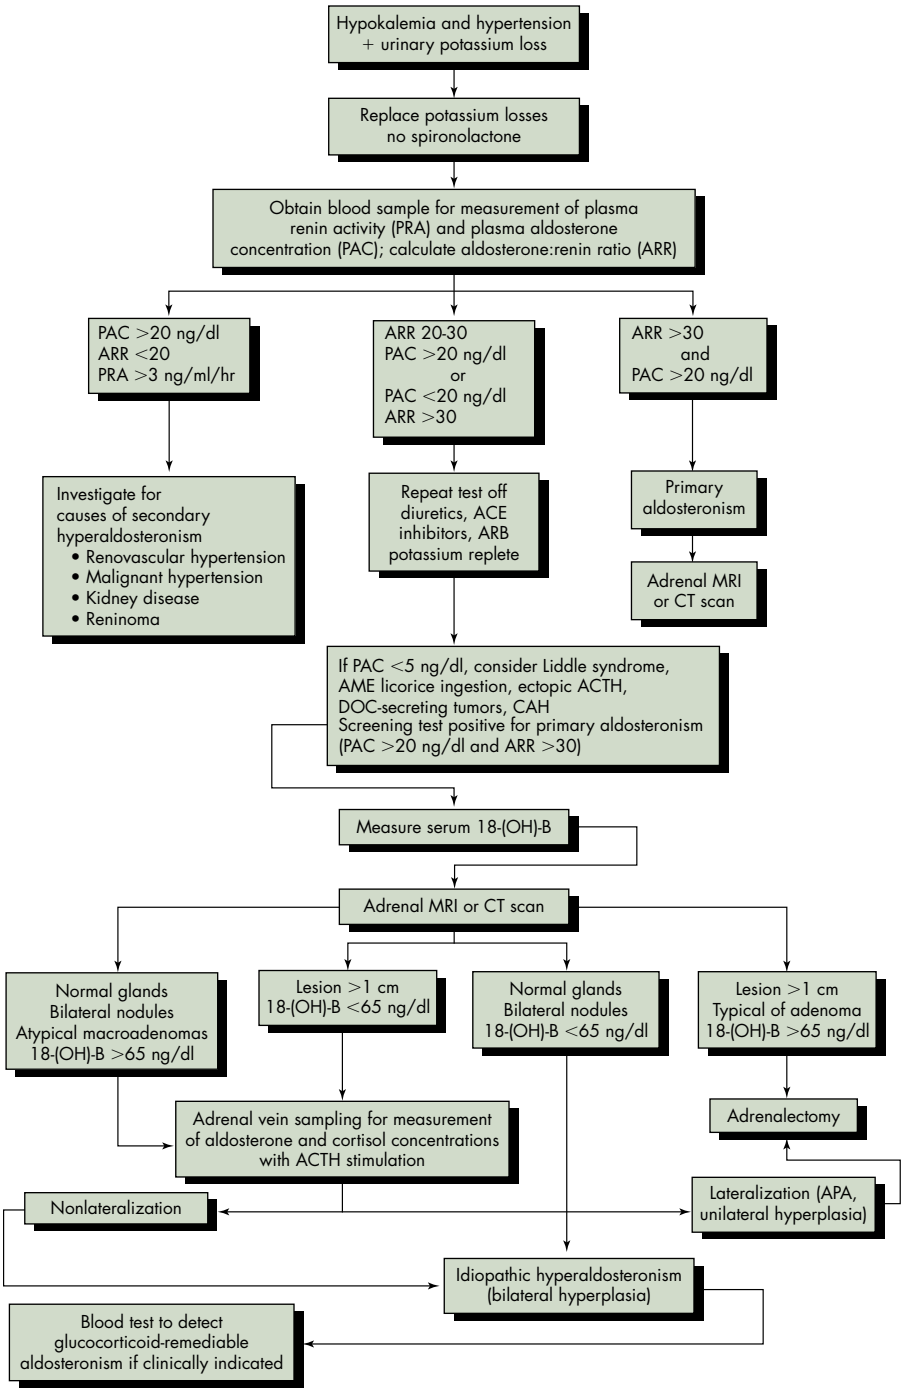

FIG. 2 Diagnostic approach to patients with suspected primary aldosteronism. Cortisol concentration ratio in an adrenal vein four times greater than that in the other adrenal vein and/or an aldosterone/cortisol concentration ratio from the vein of the unaffected adrenal that is less than the ratio in the vena cava. Urinary loss of potassium can be documented by measuring potassium excretion in a 24-hour urine collection; excretion of more than 30 mEq per day in the presence of hypokalemia indicates potassium wasting. An alternative and simpler approach is to obtain a random sample of urine to calculate the fractional excretion of potassium. A fractional excretion exceeding 10% when hypokalemia is present indicates potassium wasting. *AME,* Syndrome of apparent mineralocorticoid excess; *APA,* aldosterone-producing adenoma; *CAH,* congenital adrenal hyperplasia; *CT,* computed tomography; *DOC,* deoxycorticosterone; *ectopic ACTH,* production of corticotrophin by a tumor outside the pituitary gland; *serum 18-(OH)-B,* serum concentration of 18-hydroxycorticosterone. (From Runge MS, Greganti MA: *Netter's internal medicine,* Philadelphia, 2008, Saunders.)

PEARLS & CONSIDERATIONS

- Primary aldosteronism is more common than previously thought and should be considered in all patients with apparent resistant hypertension.
- There is more rapid decline in eGFR, increased LV mass, and increased relative risk of stroke, myocardial infarction, and atrial fibrillation in patients with primary aldosteronism than in patients with essential hypertension matched for age, gender, and blood pressure. Increased risk is attenuated but persists even when treated with a mineralocorticoid antagonist. Adrenalectomy decreases these risks to below that of the matched essential hypertension cohort.
- Frequent monitoring of blood pressure and electrolytes after adrenalectomy is necessary because normalization of blood pressure after unilateral adrenalectomy may take up to 4 months.
- Caution must be taken during interpretation of direct renin concentration (DRC) and PRA testing results because of different units used for each assay. The aldosterone-to-DRC ratio is yet to be as widely validated as the aldosterone-to-PRA ratio.

Allergic Rhinitis PTG

BASIC INFORMATION

DEFINITION

Allergic rhinitis is an immunoglobulin E (IgE)-mediated hypersensitivity response to nasally inhaled allergens that involves mucosal inflammation driven by type 2 helper T (Th2) cells that causes sneezing, rhinorrhea, nasal pruritus, and congestion. It may be seasonal or perennial.

SYNONYMS

Hay fever
IgE-mediated rhinitis
Seasonal allergic rhinitis
SAR

ICD-10CM CODES
J30.1 Allergic rhinitis due to pollen
J30.2 Other seasonal allergic rhinitis
J30.3 Other allergic rhinitis
J30.4 Allergic rhinitis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Allergic rhinitis affects approximately 10% to 20% of the U.S. population and 40% of children.
- Mean age of onset is 8 to 12 yrs.
- The prevalence of allergic rhinitis in patients presenting to their primary care provider with nasal symptoms is estimated to be 30% to 60%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Pale or violaceous mucosa of the turbinates caused by venous engorgement (this can distinguish it from erythema present in viral rhinitis)
- Nasal polyps
- Lymphoid hyperplasia in the posterior oropharynx with cobblestone appearance
- Erythema of the throat, conjunctival and scleral injection
- Clear nasal discharge
- Clinical presentation: Usually consists of sneezing, nasal congestion, cough, postnasal drip, loss of or alteration of smell, and sensation of plugged ears

ETIOLOGY

- Pollens in the springtime, ragweed in fall, grasses in the summer
- Dust, mites, animal allergens
- Smoke or any irritants
- Perfumes, detergents, soaps
- Emotion, changes in atmospheric pressure or temperature

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infections (sinusitis; viral, bacterial, or fungal rhinitis)
- Rhinitis medicamentosa (cocaine, sympathomimetic nasal drops)
- Vasomotor rhinitis (e.g., secondary to air pollutants)
- Septal obstruction (e.g., deviated septum), nasal polyps, nasal neoplasms
- Systemic diseases (e.g., Wegener granulomatosis, hypothyroidism [rare])

WORKUP

- The initial strategy should be to determine whether patients should undergo diagnostic testing or receive empirical treatment.
- Workup is often unnecessary if the diagnosis is apparent. A detailed medical history is useful in identifying the culprit allergen.
- Selected patients with allergic rhinitis that is not controlled with standard therapy may benefit from allergy testing to target allergen avoidance measures or guide immunotherapy. Allergy testing can be performed using skin testing or radioallergosorbent (RAST) testing. Immunoglobulin E (IgE) testing using newest-generation assays is also an excellent tool for diagnosing the cause of symptoms related to rhinitis. Allergy testing with skin or blood testing is most useful as confirmatory tests when the patient's history is compatible with an IgE-mediated reaction and should generally be reserved for ambiguous or complicated cases.
- Examination of nasal smears for the presence of neutrophils to rule out infectious causes and the presence of eosinophils (suggestive of allergy) may be useful in selected patients.
- Peripheral blood eosinophil counts are not useful in allergy diagnosis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Maintain allergen-free environment by covering mattresses and pillows with allergen-proof casings, eliminating carpeting, eliminating animal products, and removing dust-collecting fixtures.
- Use of air purifiers and dust filters is helpful.
- Maintain humidity in the environment below 50% to prevent dust mites and mold.
- Use air conditioners, especially in the bedroom.
- Remove pets from homes of patients with suspected sensitivity to animal allergens.
- Use of acupuncture to treat seasonal allergic rhinitis is controversial. A recent trial showed that acupuncture led to statistically significant improvement in disease-specific quality of life and antihistamine use measures after 8 weeks of treatment compared with sham acupuncture and with rescue medication alone.
- Nasal saline sprays are effective in relieving nasal dryness and congestion. Nasal irrigations can be administered via neti pot or bulb syringes or with premade saline solutions available OTC.

ACUTE GENERAL Rx

- Determine if the patient is troubled by swollen turbinates (best treated with decongestants) or blockages secondary to mucus (effectively treated by antihistamines).
- Topical nasal steroids are very effective and are preferred by many as first-line treatment for allergic rhinitis in persons 12 and older. Patients should be instructed on proper use and informed that improvement might not occur for at least 1 wk after initiation of therapy. Commonly available inhalers follow.
  1. Beclomethasone dipropionate: One to two sprays in each nostril bid
  2. Fluticasone: Initially two sprays in each nostril qd or one spray in each nostril bid, decreasing to one spray in each nostril qd based on response
  3. Flunisolide: Initially two sprays in each nostril bid
  4. Budesonide: Two sprays in each nostril bid or four sprays in each nostril qam
  5. For treatment of moderate to severe seasonal allergic rhinitis in persons age 12 or older, the best initial treatment is a combination of intranasal corticosteroid and an intranasal antihistamine. Intranasal decongestants can cause dryness, burning, and stinging of the nose and throat. They can also cause rebound nasal congestion if used as monotherapy >5 consecutive days.
  6. Azelastine is an antihistamine nasal spray effective for seasonal allergic rhinitis. Olopatadine is an intranasal H1-antihistamine alternative to azelastine in mild to moderate seasonal allergic rhinitis.
- Most oral first-generation antihistamines can cause considerable sedation and anticholinergic symptoms. The second-generation antihistamines (loratadine, fexofenadine, cetirizine, levocetirizine, desloratadine) are preferred because they do not have any significant anticholinergic or sedative effects.
- Montelukast, a leukotriene receptor antagonist commonly used for asthma, is also effective for allergic rhinitis. Usual adult dose is 10 mg qd.
- Oral decongestants such as pseudoephedrine are often used in combination with an oral H1-antihistamine for treatment of allergic rhinitis.

CHRONIC Rx

- Cromolyn sodium: One spray to each nostril three to four times daily can be used for prophylaxis (mast cell stabilizer). It should be started 2 weeks before exposure to an allergen and is typically used 3 to 4 times/day.
- Immunotherapy is generally reserved for patients responding poorly to the above treatments. Traditionally, immunotherapy consisted of subcutaneous injections of gradually increased doses of allergens. The FDA has approved several allergen extracts (Oralair, Grastek, Ragwitek, Odactra) for sublingual administration as immunotherapy.

DISPOSITION

Most patients experience significant relief with avoidance of allergens and proper use of medications.

REFERRAL

Allergy testing in patients with severe symptoms who are unresponsive to therapy or when the diagnosis is uncertain

BASIC INFORMATION

DEFINITION

Alopecia is the term used to describe involuntary hair loss, typically on the scalp but can occur anywhere over the body. *Nonscarring alopecia* is hair loss without clinically apparent scarring, inflammation, or skin atrophy. *Scarring alopecia* is characterized by permanent hair loss accompanied by tissue destruction in the form of scarring, inflammation, and/or skin atrophy.

SYNONYMS

Hair loss
Balding

ICD-10CM CODES

L63	Alopecia aerata
L63.0	Alopecia (capitis) totalis
L64	Androgenic alopecia
L64.0	Drug-induced androgenic alopecia
L64.8	Other androgenic alopecia
L64.9	Androgenic alopecia, unspecified
L65	Other nonscarring hair loss
L66	Cicatricial alopecia
L65.9	Nonscarring hair loss, unspecified
L63.8	Other alopecia areata
L65.0	Telogen effluvium

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Depends on etiology, for example:

- Alopecia areata affects 1% of the U.S. population by age 50 yr. There is a higher incidence at a younger age and both sexes are affected equally.
- Androgenetic alopecia affects males > females with 50% of Caucasian men affected by age 50 yr. Less common in Asians and African-American men, and often has later onset. By age 70, 40% of females are affected, with incidence increasing after menopause.

GENETICS: Depends on etiology, for example:

- Androgenetic alopecia is polygenic with variable penetrance and can be inherited from one or both parents.
- Certain scarring alopecias are more predominant in people with coarser hair.

ETIOLOGY

NONSCARRING:

- Failure of follicle production
- Hair shaft abnormality
- Pattern hair loss, i.e., androgenetic alopecia
- Hair breakage, i.e., trichotillomania, traction alopecia, cosmetic overprocessing
- Problem with cycling (excess shedding), i.e., telogen effluvium, anagen effluvium, loose chemotherapy anagen syndrome, alopecia areata, syphilis

SCARRING:

- Infectious: Tinea capitis with inflammation (kerion), bacterial folliculitis as in dissecting folliculitis and folliculitis decalvans
- Neoplasm: Alopecia mucinosa in cutaneous T-cell lymphoma or alopecia neoplastica due to metastatic carcinoma (breast cancer)
- Autoimmune: Chronic cutaneous lupus erythematosus
- Congenital

CLINICAL FEATURES

HISTORY: A careful history must be taken and should include time course for hair loss, the pattern of hair loss, any recent change in life situation/stresses, any associated medical conditions, new medications, any family history of hair loss, diet, hair care practices, and other skin/nail symptoms.

PHYSICAL EXAMINATION:

- General: Patient's emotional response to hair loss
- Hair/skin:
  1. Hair thinning/loss
  2. May have fine downy hairs also referred to as vellus hairs
  3. Skin may show changes consistent with inflammation, infection, and/or atrophy
  4. Women may show virilization (e.g., hirsutism)
  5. Exclamation-point hairs can be seen in alopecia areata
  6. Broken hairs of different length may be seen in traumatic alopecia
  7. Hairs that crack or crumble with palpation most often signify shaft damage due to overprocessing

DIAGNOSIS

WORKUP

- Pull test: No shower for 24 hr, 60 hairs are gently pulled from the scalp, removal of 6 or more hairs is considered positive result and indicates telogen effluvium (active shedding). Look for telogen bulbs on recovered hairs to differentiate from breaking (blunt ends).
- Punch biopsy: Mandatory when suspecting scarring alopecia. Send two punches: one for vertical and one for horizontal sectioning for histopathologic analysis, preferably by a dermatopathologist.
- Trichogram: Quantifies hair loss. Pull 25 to 50 hairs and measure proportion of anagen to catagen and telogen hairs under light microscopy: 10% to 20% telogen hairs is normal, whereas >35% is highly suspicious for telogen effluvium.
- Fig. E1 describes the evaluation and treatment of alopecia in females.

LABORATORY TESTS

Initiate laboratory studies if not clear based on clinical presentation:

- CBC: Rule out Fe deficiency
- Total Fe/ferritin: Rule out subclinical Fe deficiency
- TSH: Rule out underlying thyroid disease
- ANA: Screen for autoimmune disease
- RPR: Rule out cutaneous syphilis if history suggestive of increased risk

DIFFERENTIAL DIAGNOSIS

NONSCARRING:

- *Telogen effluvium:* This type of alopecia is usually diffuse thinning that follows significant life stress (death of loved one, high fever, severe infection, crash dieting) or change in hormones (postpartum, change in or cessation of oral contraceptives). Patient often presents with a bag of hair that has fallen out. This is caused by a large number of anagen (growing) hairs entering telogen (dying phase) simultaneously. Telogen effluvium is more common in women.
- *Androgenetic alopecia:* Gradual thinning of hair and a trend toward finer hair, which in men has a typical pattern of receding anterior bitemporal hairline resulting in an M-shaped pattern and hair loss at the vertex (Fig. E2) and in women has a typical pattern of thinning along vertex with or without frontotemporal thinning. This type of thinning is due to a combination of genetic predisposition and androgenic conversion of hair follicles into vellus-like follicles. Widening of the central hair part is often seen, leading to scalp visibility (Fig. E3). This female pattern of more diffuse hair loss is seen in 20% to 30% of adolescent males.
- *Alopecia areata:* Patches of acute hair loss (Fig. E4), typically 2 to 5 cm in diameter, with normal-appearing skin, black dots (cadaver hairs, point noir) from hair that breaks before reaching the skin's surface, and occasional "exclamation point hairs," which are evidence of hairs breaking off as they are pushed from the follicle. Fingernails may show fine pitting. On biopsy, lymphocytes surround the hair bulb and resemble a "swarm of bees," evidence of the autoimmune etiology. Patients often have positive family history. AA Universalis (AAU)—generalized loss of body hair AA Totalis (AAT)—complete loss of scalp hair.
- *Tinea:* This type of hair loss is evident in round patches, possibly with scarring, erythema, and lymphadenopathy. This is the most common type of hair loss in children. Diagnosis can be made by scraping the erythematous edge and placing the scraping with KOH under a microscope to check for hyphae. Wood's lamp only fluoresces if tinea is caused by *Microsporum* spp.; however, the most common (in the U.S.) *Trichophyton* spp. does not fluoresce. If a kerion (severe alopecia associated with bogginess) is present, it may cause scarring.
- *Traumatic alopecia (traction alopecia):* This type of hair loss is in a pattern consistent with breaking off of hairs due to traction (hair pulling) (Fig. E5) or chemical or heating agents (hair straightening or permanent). Etiology usually becomes apparent with careful history taking and visualizing the pattern of hair loss. In trichotillomania (Fig. E6), the alopecia area has an irregular shape, scalp excoriations may present, and hairs are broken at different lengths.

SCARRING:

- *Lichen planus:* The hair loss associated with LP is typically associated with scaling and atrophy of pruritic, painful skin underlying the hair loss. This hair loss is more common in middle-aged women. While there are

numerous variations in clinical presentation, the general clinical picture is one of a chronic inflammatory condition of the skin, nails, mucous membranes, and/or hair. The typical skin lesions are flat topped, violaceous lesions with white lines (Wickham striae), while the typical oral lesions are milky white.

- *Chronic cutaneous (discoid) lupus erythematosus:* This type of hair loss frequently is evident in well-demarcated, erythematous plaques in chronically sun-exposed areas of skin. Lesions exhibit hypopigmentations or hyperpigmentations, atrophy, erythema, and scaling. It may be present concurrently with SLE or be the first presenting symptom of SLE, but in most cases it is a purely cutaneous condition.
- *Tinea with kerion:* A kerion represents an exuberant delayed-type hypersensitivity reaction to the tinea capitis, resulting in one (or many) inflamed boggy plaque(s) on the scalp depending on the severity of the infection.

Rx TREATMENT

- *Telogen effluvium:* Stop offending stress/medication and in 3 to 4 months anagen recurs. Hair density should be normalized by 12 months. Multiple medications have been shown to be an inciting factor and one should consider stopping them (these include, but are not limited to, enalapril, colchicine, levodopa, metoprolol, propranolol, oral contraceptives, and lithium). Full regrowth is expected in most cases.
- *Androgenetic alopecia:* For men, the most likely first-line treatment is oral finasteride (type II 5α-reductase inhibitor) which leads to lower levels of dihydrotestosterone. This leads to hair regrowth in about 6 months, but with cessation, hair returns to pattern of loss within 6 to 9 months. Topical minoxidil has shown similar results to finasteride and can be useful in partially restoring lost hair in both men and women. Dutasteride (off-label) has been shown to be superior to finasteride in a randomized trial but requires higher doses than that used for BPH. Discontinuation of minoxidil will result in loss of regrown hair often over several months. Other options include surgical intervention with hair transplantation or hair flaps, camouflaging agents, the use of a hairpiece, or low-level light therapy. In women with elevated androgens, antiandrogens such as spironolactone, flutamide, and cimetidine may be considered.
- *Alopecia areata (AA):* Spontaneous remission occurs in patchy AA, but less commonly in AAT or AAU. Glucocorticoids (GCs) are the mainstay of treatment but have little effect on the long-term outcome of hair loss—topical GC for small patches, intralesional injection of high-potency GC, and even systemic steroids can all be temporarily effective but at the cost of glucocorticoid exposure. Induction of allergic contact dermatitis using short-contact anthralin therapy or squaric acid sensitization can be effective but tends to have significant local discomfort, thereby limiting its use. Photochemotherapy has shown some beneficial outcomes, although there is a high relapse rate after discontinuation.
- *Tinea capitis:* To effectively treat tinea capitis, oral antifungal agents must be used. Griseofulvin is considered the drug of choice in the U.S., and the recommended time course is 6 weeks to several months. Other oral agents to consider include terbinafine, itraconazole, fluconazole, and ketoconazole. If there is a kerion (area of boggy, purulent inflammation underlying the area of hair loss), the patient is at increased risk for scarring alopecia due to bacterial superinfection, and a short course of oral steroids and oral antibiotic must be considered.
- *Traumatic alopecia (traction alopecia):* First priority is stopping inciting activity/agent, ideally leading to gradual resolution of hair loss and hair regrowth.
- *Lichen planus:* Associated hair loss is often permanent; however, for symptomatic control of itching and pain, topical or oral glucocorticoids may be considered.
- *Chronic cutaneous discoid erythematosus:* The best prevention is sun protection, with SPF lotion. Treatment options center around the cautious use of topical or intralesional glucocorticoids. Hydroxychloroquine and retinoids are also used with caution.
- *Chemotherapy-induced alopecia:* Scalp cooling devices may be effective in reducing chemotherapy-induced alopecia. In a recent trial among women with stage I to II breast cancer receiving chemotherapy with taxane, anthracycline, or both, those who underwent scalp cooling were significantly more likely to have less than 50% hair loss after the fourth chemotherapy cycle compared with those who received no scalp cooling.[1]

(Modified from Habif TA: *Clinical dermatology,* ed 4, St Louis, 2004, Mosby.)

FIG. E2 Androgenetic alopecia. The scalp hair is thinned progressively but most notably between the frontal region of the scalp and the vertex. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

FIG. E3 Androgenetic alopecia. Widening of the central hair part is often seen, leading to scalp visibility. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

FIG. E4 Alopecia areata: patchy hair loss. The alopecic area is devoid of hairs, and the scalp does not present inflammatory changes. (From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.)

FIG. E5 Traction alopecia. Hair loss can be seen at the margins where hair is pulled most tightly through use of barrettes. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

FIG. E6 Trichotillomania: patchy hair loss. The alopecic area has an irregular shape and present hairs are broken at different lengths. Also note scalp excoriations. (From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.)

Alpha-1-Antitrypsin Deficiency (PTG)

BASIC INFORMATION

DEFINITION

Alpha-1-antitrypsin deficiency (AATD) is a genetic deficiency of the protease inhibitor alpha-1-antitrypsin that results in a predisposition to pulmonary emphysema and hepatic cirrhosis.

SYNONYM

AATD

ICD-10CM CODE
E88.01 Alpha-1-antitrypsin deficiency

EPIDEMIOLOGY & DEMOGRAPHICS

- Underrecognized by clinicians, but accounts for approximately 0.2% to 0.5% of chronic obstructive pulmonary disease (COPD) cases in the U.S.
- Prevalence is about 1 per 2000 to 5000 people in the United States
- Inherited as an autosomal, codominant disorder
- Most frequent mutation is in the *SERPINA 1* gene (previously known as *PI* gene)
- Most common alleles are:
  1. Normal "M" allele (MM phenotype 95% frequency in the U.S.)
  2. Deficient variant "Z" allele (1% to 2%)
  3. Deficient variant "S" allele (2% to 3%)
- Severe deficiency is most commonly due to homozygotes ZZ
- Risk of lung disease is uncertain with MZ genotype, but increased with SZ genotype (especially in smokers)
- One in 10 individuals of European descent carries one of two mutations that may result in partial alpha-1-antitrypsin deficiency

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical findings and clinical presentation are varied and depend on phenotype (see "Etiology").
- Most often affects the lungs but can also involve liver and skin.
- Classically associated with early-onset, severe, lower-lobe predominant panacinar emphysema; bronchiectasis may also be seen.
- Symptoms are similar to "typical" COPD presentation (dyspnea, cough, sputum production).
- Liver involvement includes neonatal cholestasis, cirrhosis in children and adults, and primary carcinoma of the liver.
- Panniculitis is the major dermatologic manifestation (Rare: 1 in 1000 AATD individuals).

ETIOLOGY

- Autosomal recessive genetic disorder.
- Degree of alpha-1-antitrypsin deficiency depends on phenotype.
- "MM" represents the normal genotype and is associated with alpha-1-antitrypsin levels in the normal range.
- Mutation most commonly associated with emphysema is Z, with homozygote (ZZ) resulting in approximately 85% deficit in plasma alpha-1-antitrypsin concentrations.
- Development of emphysema is believed to result from an imbalance between the proteolytic enzyme elastase, produced by neutrophils, and alpha-1-antitrypsin, which normally protects lung elastin by inhibiting elastase.
- Deficiency of alpha-1-antitrypsin increases risk of early-onset emphysema, but not all alpha-1-antitrypsin deficient individuals will develop lung disease.
- Smoking increases risk and accelerates onset of COPD.
- Liver disease is caused by pathologic accumulation of alpha-1-antitrypsin in hepatocytes.
- Similar to lung disease, skin involvement is thought to be attributable to unopposed proteolysis in skin.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

See "Chronic Obstructive Pulmonary Disease."
See "Cirrhosis."

WORKUP

Suspicion for alpha-1-antitrypsin deficiency usually results from emphysema developing at an early age (45 yr old or younger) or emphysema without risk factors (e.g., smoking, dust exposure) and with basilar predominance of disease.

LABORATORY TESTS

- Serum level of alpha-1-antitrypsin can confirm or reject suspicion of deficiency.
- Investigate possibility of abnormal alleles with genotyping.
- Pulmonary function testing is generally consistent with "typical" COPD.

IMAGING STUDIES

- Chest radiograph shows characteristic emphysematous changes at lung bases.
- High-resolution chest computed tomography (CT) usually confirms the basal-predominant emphysema (64%) and may also show significant bronchiectasis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of smoking is of paramount importance.
- Avoidance of other environmental and occupational exposures that may increase risk of COPD. Routine vaccinations are also recommended.

ACUTE GENERAL Rx

Acute exacerbations of COPD from alpha-1-antitrypsin deficiency are treated in a similar fashion to "typical" COPD exacerbations.

CHRONIC Rx

- The goal of treatment in alpha-1-antitrypsin deficiency is to increase serum alpha-1-antitrypsin levels above a minimum, "protective" threshold of 50 mg/dl.
- Although several therapeutic options are under investigation, IV administration of pooled human alpha-1-antitrypsin is currently the only approved method to raise serum alpha-1-antitrypsin levels. Alpha-1-antitrypsin (AAT) augmentation therapy has been approved by the FDA for patients with AAT deficiency who have COPD. Augmentation therapy is expensive and requires lifelong treatment. Supplemental alpha-1-antitrypsin prevents progressive lung injury but does not affect the progression of cirrhosis.
- Organ transplantation for patients with end-stage lung or liver disease is also an option.

DISPOSITION

- Prognosis of patients with alpha-1-antitrypsin deficiency will depend on phenotype and level of deficiency.
- Among patients with severe alpha-1-antitrypsin deficiency, the most common underlying causes of death are respiratory failure (45% to 72%) and cirrhosis (10% to 13%).

REFERRAL

- Referral to specialists with experience in AAT deficiency is preferred
- Pulmonary and hepatology referrals for advanced lung and liver disease, or if replacement therapy is contemplated (e.g., moderate-severe lung disease)
- Lung and liver transplantation in suitable cases

PEARLS & CONSIDERATIONS

- The liver damage arising from the mutation is not from a deficiency in alpha-1-antitrypsin but from a pathologic accumulation of alpha-1-antitrypsin in hepatocytes.
- Strong association between PI*ZZ phenotypes and liver disease has prompted recommendations for AATD testing in individuals with unexplained liver disease.
- Consider alpha-1-antitrypsin deficiency in patients presenting with lower-lobe predominant emphysema; in most smokers without alpha-1-antitrypsin deficiency, emphysema predominates in the upper lobes.
- Alpha-1-antitrypsin deficiency is believed to be under-recognized.
- The American Thoracic Society and the European Respiratory Society recommend testing for AAT deficiency in all symptomatic patients with COPD, emphysema, or asthma with irreversible obstruction, and the Global Initiative for Chronic Obstructive Lung Disease (GOLD) currently suggests, citing from WHO recommendation, that all patients with a diagnosis of COPD to be screened as well because the classic pattern with early-onset COPD (age <45 yrs) with panlobular basal emphysema may not be always observed.

AUTHORS: **Taro Minami, MD,** and **Joseph A. Diaz, MD, MPH**

BASIC INFORMATION

DEFINITION

Dementia is a syndrome characterized by progressive loss of previously acquired cognitive skills including memory, language, insight, and judgment. Alzheimer disease (AD) is thought to account for the majority (50% to 75%) of all cases of dementia.

ICD-10CM CODES

G30.0 Alzheimer disease with early onset
G30.1 Alzheimer disease with late onset
G30.8 Other Alzheimer disease
G30.9 Alzheimer disease, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Risk doubles every 5 yrs after the age of 65; above the age of 85, the annual incidence is about 10%.
PREVALENCE: Currently an estimated 5.4 million Americans have AD; 3% of the population between the ages of 65 and 74, 17% between 75 and 84, and 32% at 85 yr and older.
PREDOMINANT SEX: Female greater than male.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Spouse or other family member, usually not the patient, notes insidious memory impairment.
- Patients have difficulties learning and retaining new information and handling complex tasks (e.g., balancing the checkbook) and have impairments in reasoning, judgment, spatial ability, and orientation (e.g., difficulty driving, getting lost away from home).
- Behavioral changes, such as mood changes and apathy, may accompany memory impairment. In later stages, patients may develop agitation and psychosis.
- Atypical presentations include early and severe behavioral changes, focal findings on examination, parkinsonism, hallucinations, falls, or onset of symptoms younger than the age of 65.

DIAGNOSIS

Diagnosis of AD has evolved with the development of biomarkers that indicate AD pathology *in vivo* such as brain amyloidosis and pathological tau accumulation. Although not yet commonly used in the clinic, the integration of biomarkers into the diagnosis of AD does transform the diagnosis into one that can be established definitively while the patient is still alive. In clinical practice, the diagnosis is commonly made based on clinical history, a thorough physical and neurologic examination, and use of reliable and valid diagnostic criteria (i.e., DSM or NINDCS-ADRDA) such as the following:

- Loss of memory and one or more additional cognitive abilities (aphasia, apraxia, agnosia, or other disturbance in executive functioning)
- Impairment in social or occupational functioning that represents a decline from a previous level of functioning and results in significant disability
- Deficits that do not occur exclusively during the course of delirium
- Insidious onset and gradual progression of symptoms
- Cognitive loss documented by neuropsychologic tests
- No physical signs, neuroimaging, or laboratory evidence of other diseases that can cause dementia (i.e., metabolic abnormalities, medication or toxin effects, infection, stroke, Parkinson disease, subdural hematoma, or tumors)

Red flags for an AD diagnosis are summarized in Box 1.

The National Institute on Aging (NIA) and the Alzheimer Association (AA) recommended new diagnostic criteria and guidelines for AD in 2011, and these criteria were further revised in 2018 (Tables 1 and 2). The 100 NIA-AA criteria differed from prior DSM or NINDCS-ADRDA criteria in the following ways: (1) they recommend AD be considered a disease well before the onset of symptoms by incorporating the biomarkers in diagnosis; and (2) they define three distinct stages of AD: (1) *preclinical* AD, in which there is measurable biologic evidence of AD pathology but no symptoms; (2) *mild cognitive impairment* (MCI) due to AD, in which the patient experiences mild memory loss but no functional impairment at home or work plus biomarker evidence of AD; and (3) *dementia* due to AD, in which the patient experiences cognitive decline causing functional impairment plus biomarker evidence of AD. The 2018 NIA-AA criteria define Alzheimer disease not as three clinical syndromes but as a biologic process defined by biomarkers indicating the presence of beta amyloid (A+), pathologic tau (T+), and neurodegeneration or neuronal injury (N+). Using the ATN system and clinical status together allows an entire study population to be characterized (Fig. 1).

DIFFERENTIAL DIAGNOSIS

- Other neurodegenerative dementia (see Table 3): Frontotemporal lobar degeneration dementia with Lewy bodies, corticobasal syndrome, progressive supranuclear palsy
- Cancer (brain tumor, leptomeningeal disease)
- Infection (HIV-associated dementia, neurosyphilis, progressive multifocal leukoencephalopathy [PML])
- Toxic/metabolic (EtOH, hypothyroidism, vitamin B_{12} deficiency, mercury exposure, drug effects)
- Organ failure (dialysis dementia, Wilson disease)
- Vascular disorder (vascular dementia due to multiple strokes, severe small vessel changes, chronic vasculitis, or chronic subdural hematoma)
- Subject memory loss
- Depression (pseudodementia)

WORKUP

HISTORY & GENERAL PHYSICAL EXAMINATION:

- Medication lists should always be reviewed for drugs or home remedies that may cause mental status changes, especially anticholinergic medications, benzodiazepines, opiates, barbiturates, and neuroleptics.
- Patients should be screened for depression, because it can sometimes mimic dementia but also often occurs as a coexisting condition and should be treated.
- On examination, look for signs of metabolic disturbance, presence of psychiatric features, or focal neurologic deficits.

MENTAL STATUS TESTING: Brief mental status testing can be done easily and quickly in the office. Commonly used cognitive tests to detect dementia include the Folstein Mini-Mental State Examination (MMSE), the Mini-Cog test, and the Montreal Cognitive Assessment. The Montreal Cognitive Assessment (MoCA, www.mocatest.org/) is a highly sensitive 30-point test that takes approximately 10 minutes to administer. Cognitive domains tested include visual-spatial, attention, verbal recall, language, abstraction, and orientation. A score of 25 points or less (26 points if the patient has less than 12 yrs of education) indicates cognitive impairment. The test is available in over 35 languages, and multiple forms in English allow for repeated assessments over time. A summary of commonly used tests may be found in Table 4.

Mental status testing should include tests that assess the following cognitive functions:

BOX 1 Red Flags for an Alzheimer Disease Diagnosis

- Age younger than 65 yr
- Fluctuating level of consciousness (consider toxic-metabolic encephalopathy, Lewy body dementia)
- Behavioral, emotional, or personality disturbances overshadowing cognitive impairment (consider frontotemporal dementia, HIV dementia)
- Rapidly (6-12 mo) progressive development (consider Creutzfeldt–Jakob disease, paraneoplastic limbic encephalitis, HIV dementia, frontotemporal dementia)
- Presence of physical abnormalities:
  1. Gait impairment (consider vascular dementia, HIV dementia, NPH)
  2. Lateralized signs, e.g., hemiparesis, spasticity, other corticospinal tract signs (consider vascular dementia)
  3. Movement disorders
  4. Myoclonus (consider Creutzfeldt–Jakob disease, paraneoplastic encephalitis)
  5. Rigidity, bradykinesia (parkinsonism) (consider dementia with Lewy bodies and Parkinson disease)

Modified from Kaufman DM, Geyer HL, Milstein MJ: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.

TABLE 1 New Diagnostic Criteria

Criteria for Probable Alzheimer Disease	DSM-5 2013	Research Criteria NINCDS–ADRDA 2007	 NIA-AA 2011
Insidious onset	X	X	X
Onset over months to yrs		X	X
Progressive decline	X	X	X
Deficits are not explained by delirium or other medical or psychiatric conditions	X	X	X
Social/occupational impairment	X		X
Presence of episodic memory deficit	X	X	
Cognitive deficits in at least two domains	X		X
Neuropsychological testing required for diagnosis?	Preferably	X	Only if routine history and mental status testing are inconclusive
Abnormal PET or MRI scan		Supportive feature*	For research purposes
Genetic markers?	X	Supportive feature*	For research purposes
	Required only if there is evidence of multiple causes and no clear evidence of progression and decline in memory and another cognitive domain		
Abnormal cerebrospinal fluid marker required?		Supportive feature*	For research purposes

DSM-5, Diagnostic and Statistical Manual of Mental Disorders, fifth edition; *MRI,* magnetic resonance imaging; *NIA-AA,* National Institute on Aging–Alzheimer's Association; *NINCDS-ADRDA,* National Institute of Neurological and Communicative Disorders and Stroke–Alzheimer's Disease and Related Disorders Association; *PET,* positron emission tomography.
*At least one supportive feature is required for diagnosis of probable AD.
From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

TABLE 2 National Institute on Aging–Alzheimer's Association Criteria for Alzheimer Disease (AD)

I. Core Clinical Criteria

- Interferes with work or usual activities *and*
- Represents a decline from previous level of functioning *and*
- Not explained by delirium of psychiatric disorder.
- Documented cognitive impairment by history taking and objective cognitive assessment (bedside mental status examination or neuropsychological testing).
- A minimum of two of the following domains should be impaired:
  1. Impairment in acquisition and recall of new information (symptoms—repetitive questions and/or conversations, misplaced belongings, forgetting appointments, getting lost)
  2. Impairment in reasoning of complex tasks, poor judgment (symptoms—poor safety assessment, poor financial management, poor decision making, inability to plan complex activities)
  3. Impairment in visuospatial abilities (symptoms—inability to recognizes faces or objects or finding objects in plain view, despite good visual acuity; inability to operate simple tools; inability to orient clothing to the body)
  4. Impaired language functions (speaking, reading, writing; symptoms—difficulty thinking of common words while speaking, hesitation; speech, spelling, writing errors)
  5. Changes in personality, behavior, or comportment (symptoms—uncharacteristic mood fluctuations, e.g., agitation, poor motivation, apathy, social withdrawal, decreased interest in previous activities, loss of empathy, compulsions and/or obsessions, social impairment)

II. Probable AD Dementia (meets core criteria plus the following)

- Insidious onset (gradual over months to yrs)
- Clear history of worsening cognition *and*
- Initial and most prominent cognitive deficits fall into two categories (all must include cognitive dysfunction in at least one other domain).
  1. Amnestic—most common presentation; impairment in learning and recall of recent information
  2. Nonamnestic
     a. Language presentation—most prominent in word finding
     b. Visuospatial presentation—most prominent in spatial cognition (object agnosia, face recognition, simultanagnosia, alexia)
     c. Executive dysfunction—impaired reasoning, judgment, problem solving.
- Should not be applied if substantial cerebrovascular disease or core features of dementia with Lewy bodies (other than dementia) are present; features consistent with behavioral variant of frontotemporal dementia, primary progressive aphasia (semantic, nonfluent, or agrammatic variants), or evidence of other neurologic disease or medical comorbidity that could affect cognition
- Increased certainty if there is documented decline based on subsequent evaluations and in persons who have evidence of causative genetic mutations

III. Probable AD With Evidence of AD Pathophysiologic Process

- High probability of AD pathology if both of the following are present:
  1. β-Amyloid level is low in the cerebrospinal fluid (CSF) or there is a positive positron emission tomography (PET) scan
  2. Neuronal injury is proven with high CSF tau levels, decreased fluorodeoxyglucose-PET uptake in the temporoparietal cortex, or disproportionate atrophy in the mediobasolateral temporal lobe and medial parietal cortex on a structural MRI scan.
- Intermediate probability of AD pathology if only one of the two criteria above are met (and the other is absent or negative)

IV. Possible AD Dementia (meets core clinical criteria but has the following features)

- Atypical course—sudden onset of cognitive impairment, insufficient historical details of objective cognitive decline or progressive decline
- Causally mixed presentation—evidence of cerebrovascular disease; features of dementia with Lewy bodies (other than dementia); evidence of other neurologic disease, medical comorbidity, or pharmaceutical use that could have a substantial effect on cognition

TABLE 2 National Institute on Aging–Alzheimer's Association Criteria for Alzheimer Disease (AD)—cont'd

V. Possible AD with Evidence of AD Pathophysiologic Process

- High probability of AD pathology if both of the following are present:
  1. β-Amyloid level is low in the CSF or there is a positive PET scan
  2. Neuronal injury is proven with high CSF tau levels, decreased fluorodeoxyglucose-PET uptake in the temporoparietal cortex, or disproportionate atrophy in the mediobasolateral temporal lobe and medial parietal cortex on a structural MRI scan
- Uninformative unless the above criteria are met
- May also be a second pathophysiologic condition present to explain why the patient does not meet AD criteria (e.g., concomitant dementia with Lewy bodies)

VI. Pathophysiologically Proven AD Dementia

- Clinical and cognitive criteria for AD are satisfied *and* neuropathologic criteria demonstrate presence of AD pathology

VI. Dementia Unlikely to Be Due to AD

- Does not meet clinical criteria for AD dementia *or*
- Regardless of meeting clinical criteria for probable or possible AD dementia, there is sufficient evidence for an alternative diagnosis (e.g., HIV dementia, Huntington disease).
- Regardless of meeting clinical criteria for possible AD dementia, both β-amyloid and neuronal injury biomarkers are negative.

FIG. 1 Descriptive nomenclature: Syndromal cognitive staging combined with biomarkers. *AD,* Alzheimer disease; *MCI,* mild cognitive impairment. NOTE: Formatting denotes three general biomarker "categories" based on biomarker profiles: those with normal AD biomarkers (no color), those with non-AD pathologic change (dark gray), and those who are in the Alzheimer continuum (light gray). (From Clifford RJ Jr et al: NIA-AA research framework: toward a biological definition of Alzheimer's disease, *Alzheimer's & Dementia* 14:535-562, 2018.)

TABLE 3 Features Distinguishing Alzheimer Disease and Frontotemporal Dementia

Feature	Alzheimer Disease	Frontotemporal Dementia
Age at onset (yr)	>65	53 (mean)
Memory impairments	Early, pronounced	Subtle, at least initially, with preserved visual-spatial ability
Behavior abnormalities	None until middle or late stage	Early and prominent perseverative and compulsive behavior; hyperorality; impaired executive ability
Language impairment	Except for anomia, none until late stage	Paraphasias, anomia, decreased fluency
CT/MRI appearance	General atrophy, but especially parietal and temporal lobes	Frontal and temporal lobe atrophy
Histologic marker	Aβ accumulation	Tau accumulation

CT, Computed tomography; *MRI,* magnetic resonance imaging.
From Kaufman DM, Geyer HL, Milstein MJ: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.

TABLE 4 Commonly Used Neuropsychological Tests

Domains to Be Assessed	Tests Used with Age-Corrected and/or Education Norms for Adults Older Than 65 Yr
Premorbid ability	• North American Reading Test (NART) • Vocabulary (WAIS-IV)
Verbal memory	• Rey Auditory Verbal Learning Test (RAVLT) • California Verbal Learning Test (CVLT) • Logical Memory Test (from WMS-IV) • CERAD Word List Test
Visual memory	• Visual Reproduction (from WMS-IV) • Rey Complex Figure Drawing Test (RCFT)
Simple attention	• Digit Span (from WAIS-IV) • Trail-Making Part A
Language	• Animal Naming Test (ANT) • Controlled Oral Word Association Test (COWAT) • Boston Naming Test (BNT)
Executive function	• Trail-Making Part B • Wisconsin Card Sort Test (WCST) • Stroop • Similarities (from WAIS-IV)
Visuospatial	• Coding (from WAIS-IV) • Rey Complex Figure Test (RCFT) • Clock Drawing Test
Motor	• Grooved Pegboard Test • Finger Tapping Test
Mood	• Geriatric Depression Scale (GDS) • Hamilton Depression Rating Scale (HDRS) • Beck Anxiety Inventory (BAI)

WAIS-IV, Wechsler Adult Intelligence Scale, fourth edition; *WMS-IV,* Wechsler Memory Scale, fourth edition.
From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

- Orientation: Ask the patient to give the day, date, month, yr, and place and to name the current president.
- Attention: Ask the patient to recite the months of the yr forward and in reverse.
- Verbal recall: Ask the patient to remember three items; test for recall after a 1- and 5-min delay.
- Language: Ask the patient to write and then read a sentence; have the patient name both common and less common objects.
- Visual-spatial: Ask the patient to draw a clock and to set the hands of the clock at 11:10.

Patients with AD typically have trouble with verbal recall plus visuospatial or language deficits. Attention is usually preserved until the later stages of AD, so consider alternate diagnoses in patients who perform poorly on tests of attention. A summary of the pattern of cognitive deficits associated with different dementias and depression may be found in Table 5.

LABORATORY TESTS (TABLE 6)

- CBC
- Serum electrolytes
- Glucose
- BUN/creatinine
- Liver and thyroid function tests
- Serum vitamin B_{12}
- Syphilis serology (RPR), if supported by clinical history
- HIV screening as appropriate
- Lumbar puncture if history or signs of cancer, infectious process, or unusual clinical presentation (e.g., rapid progression of symptoms)
- EEG if there is history of seizures, episodic confusion, rapid clinical decline, or suspicion of Creutzfeldt-Jakob disease
- Apolipoprotein E genotyping, measurement of CSF tau, and amyloid, and functional imaging including positron emission tomography (PET), single-photon emission computed tomography (SPECT), or amyloid PET imaging using florbetapir (Amyvid) are not yet routinely indicated but are used in clinical trials
- Brain biopsy is usually reserved for diagnoses such as prion disease and cerebral vasculitis. Generally performed postmortem

IMAGING STUDIES

- MRI to rule out hydrocephalus, cerebrovascular disease, and mass lesions, including subdural hematoma and to look for typical patterns of atrophy such as hippocampal atrophy. CT can be used if MRI is unobtainable.
- Florbetapir-PET imaging of the brain correlates with the presence and density of beta-amyloid with high sensitivity and specificity of plaque detection, but it is not covered by most payers. Amyloid scans are not part of routine clinical practice but can be considered on a case-by-case basis. PET scans with tracers detecting tau are available as part of research protocols, correlate with the presence of neurofibrillary tangles, but are not yet FDA approved for clinical use.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Patient safety, including risks associated with impaired driving, wandering behavior, leaving stoves unattended, and accidents, must be addressed with the patient and family early and appropriate measures implemented.
- Wandering, hoarding or hiding objects, repetitive questioning, withdrawal, and social inappropriateness often respond to behavioral therapies.
- Cognitive stimulation programs are beneficial for maintenance of cognitive function and improved self-reported quality of life in patients with mild to moderate Alzheimer disease.

ACUTE GENERAL Rx

None

CHRONIC Rx

- Symptomatic treatment of memory disturbance (Table 7):
  1. Cholinesterase inhibitors (ChEIs): Donepezil (Aricept), galantamine (Razadyne), and rivastigmine (Exelon)
     a. FDA approved for the treatment of mild to moderate AD with the exception of donepezil, which is approved for mild, moderate, and severe dementia. Common side effects include vivid dreams, bradycardia, and gastrointestinal side effects (nausea, diarrhea, and anorexia). Gastrointestinal side effects may be bothersome enough to require either a slower escalation of dosage or switching to another agent. The rivastigmine patch has lower rates of gastrointestinal side effects than the oral agents. Table 8 summarizes some instruments used to monitor clinical response of AD to pharmacologic therapy.

TABLE 5 Patterns of Cognitive Impairment by Domain and Dementia

Episodic Memory	Attention	Language	Executive	Visuospatial		Behavioral Symptoms
Alzheimer disease	(I)	Simple (P) Divided (I)	Phonemic (P) Semantic (I) Naming (I)	(I)	Simple (P) Complex (I)	Early apathy, late psychotic symptoms
Mild cognitive impairment—amnestic	Immediate and Delayed recall (I); Recognition (I)	Simple (P) Divided (P)	(P)	(P)	(P)	(P)
Vascular dementia	Immediate and Delayed recall (V) Recognition (P)	Simple (P) Divided (I)	(I)	(I)	(P)	Depression
Behavioral variant FTLD	(V)	Simple (P) Divided (I)	(I)	(I)	(P)	Disinhibition, apathy, hyperorality, inappropriate social interaction
Semantic variant PPA	(P)	(P)	(I) Comprehension (I) Fluency	(P)	(P) (I) Visual agnosia	(P)
Nonfluent variant PPA	(P)	(P)	(I) Fluency (P) Comprehension, (I) Expressive speech	(P)	(P)	(P)
Parkinson disease dementia	(V) Immediate and Delayed recall (P) recognition	(I)	(P)	(I)	(I)	Depression, possible hallucinations, psychomotor slowing
Dementia with Lewy bodies	(V) Immediate and Delayed recall (P) Recognition	(V)	(V)	(I)	(I)	Hallucinations, delusions
Depression	(V) Immediate and Delayed recall (P) Recognition +	(V)	(V) Fluency (P) Naming	I/V	(P)	Psychomotor slowing, apathy

FTLD, Frontotemporal lobar degeneration; *I,* impaired; *P,* preserved; *PPA,* primary progressive aphasia; *V,* variable.
From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

TABLE 6 Laboratory Evaluation of Patients with Dementia

Type of Study	Examples
Basic studies, excluding reversible with specific indication from history for causes of dementia or examination	• Complete blood count (CBC) • Chemistry or metabolic panel (SM-17) • Thyroid function tests (thyroid-stimulating hormone [TSH]) • Vitamin B_{12}, folate levels • Computed tomography (CT) or magnetic resonance imaging (MRI) • HIV testing • Sedimentation rate • Hemoglobin A1C (Hb A1C) • Urinalysis • Chest x-ray • Urine or plasma for drugs or heavy metals
Adjuvant studies to aid diagnosis	
Other tests as indicated by history or physical or neurologic examination	• Single-photon emission computed tomography (SPECT) • Positron emission tomography (PET) • Lumbar puncture with cerebrospinal fluid for β-amyloid

From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

2. NMDA receptor antagonist: Memantine (Namenda)
   a. FDA approved for the treatment of moderate to severe AD. Common side effects include constipation, dizziness, or headache. Memantine is contraindicated in patients with renal insufficiency or history of seizures.
- Symptomatic treatment of neuropsychiatric and behavioral disturbances (Table 9).
- Depression, agitation, delusions, or hallucinations may respond to medications.

DISPOSITION & REFERRAL

- Patients with complex or atypical presentations or challenging management issues should be referred to a neurologist or another specialist with expertise in dementia.
- Approximately 1 in 8 hospitalized patients with AD who develop delirium will have at least one adverse outcome (e.g., institutionalization, cognitive decline, death) associated with delirium.
- Family education and support may help reduce need for skilled nursing facility and reduce caregiver stress, depression, and burnout.

PEARLS & CONSIDERATIONS

The physician should make a thorough search for the treatable causes of dementia. Current American Academy of Neurology practice parameters recommend:
- Treat cognitive symptoms of AD with ChEIs.
- Treat agitation, psychosis, and depression.
- Encourage caregivers to participate in educational programs and support groups.

TABLE 7 Symptomatic Treatment of Memory Disturbance

	Initial Dose	Target Dose
Donepezil	5 mg qd for 4-6 wk	10 mg qd
Rivastigmine	1.5 mg bid with food, increase by 1.5 mg bid weekly	3-6 mg bid
Galantamine	4 mg bid with food, increase by 4 mg bid every 4 wk	8-12 mg bid
Memantine	5 mg qd, increase by 5 mg weekly	10 mg bid

TABLE 8 Instruments Used to Monitor Clinical Response of Alzheimer Disease (AD) to Pharmacologic Therapy

Mini-Mental State Examination

- Global measure of cognition widely used by physicians and third-party caregivers
- Assesses orientation, registration, recall, language, and attention
- Uses a 30-point scale
- Requires ≈5-10 min to complete
- Sensitivity, 80% to 90%; specificity, 80%
- Administered by psychometricians, nurses, and physicians
- AD typically advances by 3 points/yr

Clock Drawing

- Global measure of cognition widely used by physicians
- Multiple scoring systems with proven validity; sensitivity, 59%; specificity, 90%
- Assesses multiple cognitive domains in a single test
- 1-2 min to complete
- Minimal training to administer

Geriatric Depression Scale

- Evaluates depressive symptoms in patients
- Requires 5 min to complete
- Very useful in assessing depression in new patients and in follow-up
- Minimal training to administer
- Ease of administration has led to rapid spread in its use.

From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

TABLE 9 Treatment of Behavioral and Neuropsychiatric Symptoms

	Initial Dose	Maximum Dose
Atypical Antipsychotics		
Olanzapine	2.5 mg qd to bid, may increase by 2.5 mg as needed	7.5 mg bid
Quetiapine	25 mg bid, may increase by 25 mg every 2 days	250 mg tid
Antidepressants		
Sertraline	25-50 mg qd, may increase by 25 mg every wk	200 mg qd
Escitalopram	10 mg qd, may increase after 1 wk to 20 mg qd	10 mg qd

COMMENTS

- Ginkgo biloba is marketed widely as effective in delaying cognitive impairment; however, trials have shown that it is not effective in reducing the incidence of Alzheimer dementia or dementia overall.
- Higher midlife fitness levels seem to be associated with lower hazards of developing all-cause dementia later in life independent of cerebrovascular disease. Exercise also may slow the rate of functional deterioration in mild AD.
- Even moderate adherence to the MIND (the Mediterranean-DASH Intervention for Neurodegenerative Delay) diet, a hybrid of the Mediterranean and DASH diets specifically designed to optimize brain health, has been shown to reduce the incidence of AD.
- Antipsychotics should be used with extreme caution in treating dementia-related psychosis. All antipsychotics carry a warning from the FDA stating that the medication is not approved for dementia-related psychosis because elderly patients on either conventional or atypical antipsychotics experience an increased risk of death due to cardiovascular or infectious causes.
- Lower plasma beta-amyloid 42/40 is associated with greater cognitive decline among elderly persons without dementia over 9 yr, and this association is stronger among those with low measures of cognitive reserve.
- Apolipoprotein E (APOE) is the main cholesterol-carrying molecule in the brain, and it exists in three allelic variants: E2, E3, and E4. The E3 allele is most common and has a neutral influence on developing AD, whereas the E2 allele, the rarest allele, may be protective against AD. The E4 alleles are well-established heterozygotes at approximately 3 times AD risk factor. However, neither E4 heterozygosity or homozygosity is required or sufficient to cause AD. Among Caucasians, E4 heterozygosity increases the risk of developing AD approximately threefold, whereas E4 homozygosity increases AD risk by approximately 15 times compared to the E3/E3 baseline. The APOE E4 allele is also associated with an earlier age of onset of AD. Because the benefits of genetic testing are often modest, and the tests themselves are often imprecise in identifying risk, the test is generally discouraged. Recent trials, however, reveal that the disclosure of *APOE* genotyping results to adult children of patients with AD did not result in significant short-term psychological risks. Test-related distress was reduced among those who learned that they were *APOE4* negative. Persons with high levels of emotional distress before undergoing genetic testing are more likely to have emotional difficulties after disclosure.

BASIC INFORMATION

DEFINITION

Amaurosis fugax is a temporary loss of monocular vision caused by transient retinal ischemia.

ICD-10CM CODE
G45.3 Amaurosis fugax

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): An uncommon but important presentation of carotid artery disease
PEAK INCIDENCE: Approximately 55 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Onset is sudden, typically lasting seconds to minutes, and often accompanied by scotomas such as a shade or curtain being pulled over the front of the eye (usually downward).
- Vision loss can be complete, hemianopic, or quadrantic.
- Acute stage: Cholesterol emboli may be seen in retinal artery (*Hollenhorst plaque*).

ETIOLOGY

- Usually embolic from either the internal carotid artery or the heart
- Cardiac embolus most commonly due to atrial fibrillation
- Internal carotid artery embolus will be apparent as carotid stenosis on carotid imaging such as CT angiography, MR angiography, or carotid ultrasound
- Giant cell arteritis causing inflammation of retinal arteries
- Hyperviscosity syndromes, such as sickle cell disease, which causes ischemia in the vascular territory of the ophthalmic artery
- Hypercoagulable states
- Reversible cerebral vasoconstriction syndrome

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Retinal migraine: In contrast to amaurosis, the onset of visual loss develops more slowly, usually over 15 to 20 min.
- Transient visual obscurations occur in the setting of papilledema; intermittent rises in intracranial pressure briefly compromise optic disc perfusion and cause transient visual loss lasting 1 to 2 seconds. The episodes may be binocular. If the visual loss persists at the time of evaluation (i.e., vision has not yet recovered), then the differential diagnosis should be broadened to include:
  1. Anterior ischemic optic neuropathy: Arteritic (classically giant cell arteritis [GCA]) or nonarteritic
  2. Central retinal vein occlusion

WORKUP

- Workup should focus on embolic sources, but GCA should always be considered.
- Careful examination of retina; embolus may be visible and confirm the diagnosis (Fig. 1).
- Auscultation of arteries for carotid bruits.
- Examination of all pulses and for temporal artery tenderness.
- Inquire about symptoms of GCA (scalp tenderness, headache, fever, jaw claudication).
- Examine for signs of hemispheric stroke resulting from intracranial atherosclerosis (contralateral limb and facial weakness or sensory loss, aphasia, etc.).

LABORATORY TESTS

- Complete blood count with erythrocyte sedimentation rate and C-reactive protein.
- Serum chemistries, including lipid profile.
- Cardiac enzymes and ECG.
- Hypercoagulable workup is discretionary based on younger age and history.

IMAGING STUDIES

- CT or MR angiography of head and neck preferred to examine carotid and intracranial vasculature. Carotid ultrasound if contraindication to MR or CT angiography
- MRI of the brain with diffusion-weighted imaging to look for infarcts, especially those presenting with focal neurologic disturbances
- Transthoracic echocardiography is indicated to screen for sources of emboli in patients with evidence of heart disease and in patients without an evident source for transient neurologic deficit. Transesophageal echocardiography is more sensitive for detecting cardiac sources of emboli (ventricular mural thrombus, atrial appendage, patent foramen ovale, aortic arch)
- Extended monitoring for atrial fibrillation if neither carotid stenosis nor giant cell arteritis is found to be the etiology

TREATMENT

NONPHARMACOLOGIC THERAPY

- Diet (decrease saturated fatty acids and high-cholesterol foods)
- Exercise
- Cessation of tobacco use

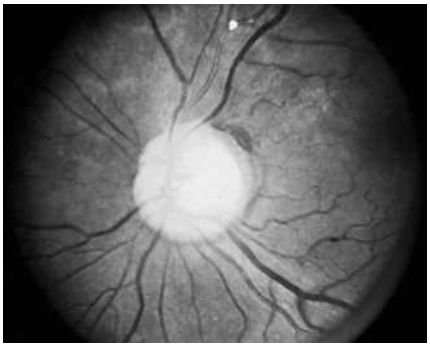

FIG. 1 A cholesterol crystal embolus lodged at an arterial bifurcation. (From Stein JH [ed]: *Internal medicine,* ed 5, St Louis, 1998, Mosby.)

ACUTE GENERAL Rx

- Investigate as an emergency
- Aspirin
- If GCA is suspected, start prednisone and refer for temporal artery biopsy within 48 hr (see "Giant Cell Arteritis" in Section I)

CHRONIC Rx

- Reduce risks by carotid endarterectomy if stenosis >50%. Carotid stenting may be performed in high-risk surgical candidates.
- Manage vascular risk factors such as hypertension, hyperlipidemia (statin therapy), diabetes, smoking cessation, etc.
- Antiplatelet therapy due to arterial atherosclerosis and postcarotid intervention; anticoagulation if etiology is atrial fibrillation.

DISPOSITION

Among patients with >50% carotid stenosis who do not undergo carotid endarterectomy, those who present with transient monocular blindness have an approximate 10% risk of stroke within 3 yr compared with an approximate 20% risk in patients who present with a hemispheric transient ischemic attack (TIA).

REFERRAL

- As with any TIA, emergent inpatient workup in a hospital that is a certified stroke center, if possible.
- If significant carotid stenosis, consider either carotid endarterectomy or carotid stenting for the following:
  1. Ipsilateral high-grade (≥70%) stenosis, but consider for ipsilateral stenosis of 50% to 69%
  2. Multiple TIAs despite medical therapy in the setting of high-grade or ulcerative disease

PEARLS & CONSIDERATIONS

- Cholesterol emboli in retinal arteries on fundoscopy confirm the diagnosis.
- Recognize that transient visual loss has multiple other causes.
- Refer to emergent evaluation like any other transient ischemic attack.

BASIC INFORMATION

DEFINITION

Amblyopia refers to decreased vision in one or both eyes as a result of insufficient stimulation of the developing visual system. The most common etiologies of amblyopia are ocular misalignment (strabismus) and unequal refractive error (anisometropia). Less commonly, amblyopia results from bilateral high refractive error (ametropic) or blockage of the ocular media (deprivation).

SYNONYMS

Deprivation amblyopia (formerly amblyopia ex anopsia)
Occlusion amblyopia
Strabismic amblyopia
Refractive amblyopia
Lazy eye

ICD-10CM CODES

H53.009	Unspecified amblyopia, unspecified eye
H53.001	Unspecified amblyopia, right eye
H53.002	Unspecified amblyopia, left eye
H53.009	Unspecified amblyopia, unspecified eye
H53.019	Deprivation amblyopia, unspecified eye
H53.011	Deprivation amblyopia, right eye
H53.012	Deprivation amblyopia, left eye
H53.013	Deprivation amblyopia, bilateral
H53.029	Refractive amblyopia, unspecified eye
H53.021	Refractive amblyopia, right eye
H53.022	Refractive amblyopia, left eye
H53.023	Refractive amblyopia, bilateral
H53.039	Strabismic amblyopia, unspecified eye
H53.031	Strabismic amblyopia, right eye
H53.032	Strabismic amblyopia, left eye
H53.033	Strabismic amblyopia, bilateral

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 1% to 5% of the general population. Amblyopia is the leading cause of vision loss in children. It is also the cause of permanent vision loss in approximately 2.9% of adults.
PREVALENCE (IN U.S.): High incidence in premature infants with drug-dependent mothers and in neurologically impaired children. Children with a family history of strabismus, amblyopia, or high refractive errors are at increased risk.
PREDOMINANT SEX: None
PREDOMINANT AGE: Childhood
PEAK INCIDENCE: Childhood

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Decreased vision using best refraction in the presence of normal retinal and optic nerve appearance (Fig. E1).

ETIOLOGY

- Refractive errors
- Strabismus
- Visual deprivation from congenital cataract, corneal opacities, ptosis or nystagmus
- Occlusion from patching (rare)
- Malnutrition or vitamin deficiency

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Central nervous system (CNS) disease (i.e., cortical visual impairment)
- Optic nerve disorders
- Corneal or other eye diseases
- Retinal disorders
- Malingering or secondary gain (i.e., desire for glasses in children—more commonly girls)

WORKUP

- Complete eye examination to find the cause of decreased vision. Referral to an ophthalmologist is recommended for any child with a visual acuity in either eye of ≤20/40 or a two-line difference in acuity between the eyes, or for a preverbal or nonverbal child who fails a photoscreening test.
- Ocular motility evaluation.

LABORATORY TESTS

Usually none

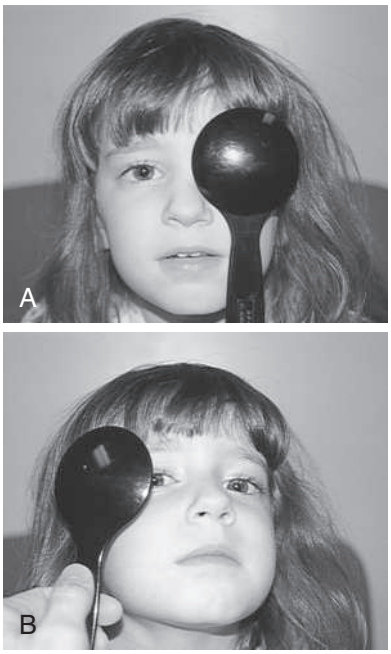

FIG. E1 A, This child happily fixes with her right eye and does not object if the left eye is covered. **B,** When the right eye is covered, she moves her head away and tries to remove the cover, demonstrating a fixation preference for the right eye and amblyopia of the left eye. (From Hoekelman R [ed]: *Primary pediatric care,* ed 3, St Louis, 1997, Mosby.)

IMAGING STUDIES

Usually not necessary unless a CNS abnormality is suspected.

TREATMENT

- Treatment depends on the age of the patient and etiology of the amblyopia.
- Glasses to align eyes in certain types of strabismus and/or to correct significant refractive errors.
- Patching or atropine eye drops are both effective depending on the type of amblyopia. Penalization of the better-seeing eye with atropine 1% drops or patching are used for varying lengths of time, usually months, depending on patient age, response, and compliance. In general, younger patients (<age 5 yr) respond faster and more fully than older children. Older children (>10 yr) who have never been treated can sometimes still respond to amblyopia therapy.
- Digital "virtual reality" viewing devices that selectively stimulate the amblyopic eye are currently under development and beginning to be marketed as treatment for amblyopia.
- Surgery for deprivation amblyopia (i.e., congenital cataract, severe congenital ptosis).

CHRONIC RX

- Maintenance treatment with glasses, patching, or atropine may be necessary until age 9 or 10 yr.
- Monitoring until visual maturity, which occurs around age 9 or 10 yr, is important to avoid relapses.

REFERRAL

To ophthalmologist if vision is compromised

PEARLS & CONSIDERATIONS

COMMENTS

- The earlier the diagnosis, the better the outcome. Amblyopia is more responsive to treatment in children younger than 5 yr of age. Although the average treatment response is weaker in children over age 5 yr, some older children show response to treatment.
- The success of therapy is highly dependent on treatment compliance.
- Amblyopia recurs in 25% of children after patching is discontinued.

Amebiasis

BASIC INFORMATION

DEFINITION

Amebiasis is an infection caused by the protozoal parasite *Entamoeba histolytica.* Although primarily an infection of the colon, amebiasis may cause extraintestinal disease, particularly liver abscess.

SYNONYM

Amebic dysentery (when severe intestinal infection)

ICD-10CM CODES

A06.9 Amebiasis, unspecified
A06.1 Chronic intestinal amebiasis
A06.7 Cutaneous amebiasis

EPIDEMIOLOGY & DEMOGRAPHIC

INCIDENCE (IN U.S.): 1.2 cases per 100,000 U.S. population. Highest in institutionalized patients, travelers to/immigrants from developing nations, and those who practice oral-anal sex

PREVALENCE: In U.S.: 4% (80% of infections asymptomatic). In the developing world: Still accounts for 9% of all deaths in children <5 yr of age

PREDOMINANT SEX:

- Equal sex distribution in general
- Striking male predominance of liver abscess

PREDOMINANT AGE: Second through sixth decades

PEAK INCIDENCE: Peaks at age 2 to 3 yr and >40 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Often nonspecific
- Approximately 20% of cases symptomatic:
  1. Diarrhea, which may be bloody
  2. Abdominal and back pain
- Abdominal tenderness in 83% of severe cases
- Fever in 38% of severe cases
- Hepatomegaly, right upper quadrant tenderness, and fever in almost all patients with liver abscess (may be absent in fulminant cases)

ETIOLOGY

- Caused by the protozoal parasite *E. histolytica, E. dispar, and E. moshkovskii.* The latter two are 10 times more common but nonpathogenic and difficult to distinguish from *E. histolytica* morphologically.
- Transmission by the fecal-oral route. Risk factors are summarized in Box E1. It is highly infectious requiring ingestion of only a small number of cysts in contaminated water or food for infection.
- Infection usually localized to the large bowel, particularly the cecum where a localized mass lesion (ameboma) may form.
- Extraintestinal infection in which the organism invades the bowel mucosa and gains access to the portal circulation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Severe intestinal infection possibly confused with ulcerative colitis or other infectious enterocolitis syndromes, such as those caused by *Shigella, Salmonella, Campylobacter,* or invasive *Escherichia coli*
- In elderly patients: Ischemic bowel possibly producing a similar picture

WORKUP

- Stool antigen testing is more sensitive than ova and parasite examination for the diagnosis of amebiasis
- Three stool specimens over a period of 7 to 10 days to search for cysts or trophozoites has a sensitivity of 85% to 95%, but microscopy cannot differentiate between the species
- Concentration and staining the specimen with Lugol iodine or methylene blue to increase the diagnostic yield
- Fecal leukocytes not always present

LABORATORY TESTS

- Fecal enzyme-linked immunosorbent assay (ELISA) antigen detection is specific for *E. histolytica* (87% percent sensitivity and >90% specificity as compared with culture) and also useful for diagnosis of liver abscess.
- PCR-based assays on stool: 90% to 95% sensitive; 95% to 100% specific.
- Mucosal biopsy is occasionally necessary to look for cysts or trophozoites.
- Serum antibody assays specific for *E. histolytica* are available and are particularly sensitive and specific for extraintestinal infection or severe intestinal disease but may not distinguish recent from remote infection.
- Aspiration of abscess fluid is used to distinguish amebic from bacterial abscesses.

Box E1 Risk Factors for Amebiasis in the United States

- Hispanic/Asian/Pacific Islanders: 50% of U.S. cases reported to the Centers for Disease Control and Prevention
- Travelers to endemic regions of the world: 0.3% incidence in one study
- Institutions for intellectually disabled
- Men who have sex with men
- Men: 90% amebic liver abscesses found in men; rare in children
- Immunodeficiency

Modified from Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

IMAGING STUDIES

Abdominal imaging studies (sonography or CT scan) to diagnose liver abscess

TREATMENT

ACUTE GENERAL Rx

- *Entamoeba histolytica* causes amoebic dysentery and requires treatment. Treatment is recommended for all infected patients. Other species of *Entamoeba* may colonize the gastrointestinal tract but are not pathogenic and do not mandate treatment.
- Table E1 summarizes drug treatment options for amebiasis in adults and children. Metronidazole or tinidazole is recommended initially for parasitic clearance. It is then followed by an intraluminal amebicide (paromomycin or diloxanide) for cyst clearance.
- Liver abscess is generally responsive to medical management but surgical intervention indicated for extension of liver abscess into pericardium or for toxic megacolon.

DISPOSITION

Host immunity incomplete and reinfection rate high for patients remaining at risk

REFERRAL

- For consultation with infectious diseases specialist for extraintestinal infection or persistent or relapsing intestinal infection
- For surgical consultation:
  1. For toxic megacolon
  2. For impending rupture of or extension of liver abscess into adjacent structures

PEARLS & CONSIDERATIONS

COMMENTS

- Infection with other intestinal parasites, particularly *Giardia lamblia,* may coexist with amebiasis.
- There is a high prevalence of *E. dispar* in homosexual males, which is nonpathogenic but may be difficult to distinguish from the pathogen *E. histolytica.*
- In the U.S., *E. histolytica* is still the third most frequently isolated pathogen in returning travelers with infectious gastroenteritis.

TABLE E1 Drug Treatment for Amebiasis

Medication	Adult Dosage (Oral)	Pediatric Dosage (Oral)*
Invasive Disease		
Metronidazole	Colitis or liver abscess: 750 mg tid for 7-10 days	Colitis or liver abscess: 35-50 mg/kg/day in three divided doses for 7-10 days
or		
Tinidazole	Colitis: 2 g once daily for 3 days Liver abscess: 2 g once daily for 3-5 days	Colitis: 50 mg/kg/day once daily for 3 days Liver abscess: 50 mg/kg/day once daily for 3-5 days
Followed by:		
Paromomycin (preferred)	500 mg tid for 7 days	25-35 mg/kg/day in three divided doses for 7 days
or		
Diloxanide furoate† or	500 mg tid for 10 days	20 mg/kg/day in three divided doses for 7 days
Iodoquinol	650 mg tid for 20 days	30-40 mg/kg/day in three divided doses for 20 days
Asymptomatic Intestinal Colonization		
Paromomycin (preferred) *or* Diloxanide furoate† *or* Iodoquinol	As for invasive disease	As for invasive disease

tid, Three times a day.
*All pediatric dosages are up to a maximum of the adult dose.
†Not available in the United States.

Amenorrhea ALG PTG

BASIC INFORMATION

DESCRIPTION

- *Amenorrhea* means absence of menstruation. It is classified as either primary or secondary depending on whether the patient has had previous menstrual cycles.
- Primary amenorrhea is defined as the absence of menses by age 15 in the presence of secondary sexual characteristics. However, in the absence of these secondary sexual features by the age of 13 yr old, one should begin the workup for primary amenorrhea.
- Secondary amenorrhea is the absence of menses for more than 6 mo in a patient who has had previous normal menstrual progesterone withdrawal cycles.

ICD-10CM CODES

N91.0 Primary amenorrhea
N91.1 Secondary amenorrhea
N91.2 Amenorrhea, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Incidence of primary amenorrhea and secondary amenorrhea in the U.S. is <1% and 5% to 7%, respectively.
- There is no racial or ethnic predilection.

ETIOLOGY

- Physiologic amenorrhea
  1. Pregnancy
  2. Lactation
  3. Constitutional Delay of Puberty
  4. Menopause
- Pathologic amenorrhea
  1. Primary amenorrhea (% frequency)
     a. Hypergonadotropic hypogonadism (43%)
        (1) 45 X (27%)
        (2) 46 XX (14%)
        (3) 46 XY (2%)
     b. Eugonadism (30%)
        (1) Müllerian agenesis (15%)
        (2) Vaginal septum (3%)
        (3) Imperforate hymen (1%)
        (4) Polycystic ovarian syndrome (7%)
        (5) Congenital adrenal hyperplasia (1%)
        (6) Cushing and thyroid disease (2%)
        (7) Androgen insensitivity (1%, Table E1)
     c. Hypogonadotropic hypogonadism (27%)
        (1) Constitutional delay (14%)
        (2) GnRH deficiency (5%)
        (3) Other CNS disease (1%)
        (4) Pituitary diseases (5%)
        (5) Eating disorders, stress (2%)
  2. Secondary amenorrhea
     a. Hypergonadotropic hypogonadism (10.5%)
        (1) 46, XX with gonadal failure (10%)
        (2) Abnormal karyotype (0.5%)
     b. Hypogonadotropic hypogonadism (67.5%)
        (1) Polycystic ovary syndrome (PCOS) (28%)
        (2) Eating disorders, stress (15.5%)
        (3) Hypothyroidism (1.5%)
        (4) Sheehan syndrome (1.5%)
        (5) Cushing syndrome (1%)
        (6) Pituitary tumor/empty sella (2%)
     c. Hyperandrogenism (2%)
        (1) Nonclassic congenital adrenal hyperplasia (0.5%)
        (2) Ovarian tumor (1%)
     d. High prolactin (13%)
     e. Anatomic (7%, Asherman syndrome)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Turner syndrome
  1. Usually presents with primary amenorrhea unless mosaic
  2. Short stature
  3. Epicanthic folds
  4. Low-set ears
  5. High-arched palate
  6. Micrognathia
  7. Sensorineural hearing loss
  8. Otitis media
  9. Webbing of the neck
  10. Pigmented nevi
  11. Square/shield chest
  12. Widely spaced nipples
  13. Absent breast development
  14. Bicuspid aortic valve
  15. Coarctation of aorta
  16. Cubit valgus
  17. Short fourth metacarpal
  18. Hyperconvex nails
  19. Leg edema
  20. Renal abnormalities
  21. Autoimmune disorders including thyroiditis
  22. Diabetes mellitus
- Pure gonadal dysgenesis
  1. Unlike Turner syndrome, has no dysmorphic features
- Müllerian agenesis
  1. Sporadic inheritance
  2. Primary amenorrhea
  3. Normal breast development
  4. Normal pubic and axillary hair
  5. Normal female external genitalia
  6. Absent uterus and upper part of vagina
  7. Ovaries present
  8. Renal and vertebral anomalies in some patients; renal agenesis should be evaluated
- Transverse vaginal septum and imperforate hymen
  1. Primary amenorrhea
  2. Progressive cyclic lower abdominal pain
  3. Imperforate hymen or transverse vaginal septum on pelvic examination
  4. Perirectal fullness from hematocolpos
- Androgen insensitivity syndrome
  1. Primary amenorrhea
  2. X-linked recessive inheritance in some patients
  3. Normal breast development
  4. Absent pubic and axillary hair
  5. Testis may be present in the groin or inguinal canal
  6. Uterus and vagina absent
  7. No associated renal or vertebral anomalies
- Adult-onset congenital adrenal hyperplasia
  1. More frequently seen in Ashkenazi Jewish, Inuit Native American, French Canadian, and Mexican populations than other populations
  2. Mimics the presentation of PCOS
  3. Features of hyperandrogenism (virilization, hirsutism, acne)
  4. Hypertension
- 5-alpha reductase deficiency
  1. Primary amenorrhea
  2. Undergo virilization at puberty
- PCOS
  1. Usually presents with secondary amenorrhea and oligomenorrhea
  2. Diagnosed with ≥2/3 of the Rotterdam Criteria:
     a. Oligo/anovulation
     b. Hyperandrogenism
     c. Polycystic ovaries on ultrasound
  3. Associated with the metabolic syndrome and obesity (60% to 80% of PCOS patients)
  4. Insulin resistance, predisposition to type 2 diabetes mellitus
- Cushing syndrome (rare disorder, prevalence 1/1,000,000)
  1. Secondary amenorrhea
  2. Features of hyperandrogenism
  3. Abnormal fat distribution (dorsocervical fat pad [buffalo hump], spider legs, significant central obesity)
  4. Abdominal striae due to weakening of skin integument
  5. Easy bruising
  6. Hypertension
  7. Proximal muscle weakness
- Hypothyroidism
  1. Secondary amenorrhea
  2. Lethargy
  3. Constipation
  4. Decreased appetite
  5. Weight gain
  6. Cold intolerance
  7. Hair loss
  8. Dry skin
  9. Bradycardia
- Primary ovarian insufficiency (previously premature ovarian failure)
  1. Secondary amenorrhea prior to the age of 40 and elevated gonadotropins (follicle-stimulating hormone [FSH] and luteinizing hormone [LH])
  2. History of oophorectomy or pelvic radiation or chemotherapy
  3. Vasomotor symptoms
  4. Dry, thin vaginal mucosa without rugosity
  5. Associated autoimmune or karyotypic abnormalities possible
- Hyperprolactinemia
  1. Usually presents with secondary amenorrhea
  2. History of use of drugs such as antipsychotics, oral contraceptive (OC) pills, antidepressants, antihypertensives, H2 blockers, opioids, etc.

TABLE E1 Congenital Anatomic Causes of Primary Amenorrhea with Normal Breast Development*

Diagnosis	Müllerian Agenesis	Androgen Insensitivity (AI)	Transverse Vaginal Septum	Imperforate Hymen
Patients with primary amenorrhea†	15%	1%	3%	1%
Patients with primary amenorrhea and apparent obstruction or absence of vagina†	75%	5%	15%	5%
Chromosomes‡	46,XX	46,XY	46,XX	46,XX
Gonads	Ovaries	Testes	Ovaries	Ovaries
Serum testosterone‡	Normal female level	Normal male level (high)	Normal female level	Normal female level
Vagina	Absent or shallow	Absent or shallow	Obstructed by septum which may be thick or thin, high or low	Obstructed by thin membrane, which may look blue from hematocolpos
Axillary/pubic hair	+	Absent unless AI is incomplete	+	+
Cyclic pain	±	–	+	+
Uterus	Absent or rudimentary	–	+	+
Mass	–	–	+ Can present with acute urinary retention as hematocolpos mass obstructs urethra	+ Can present with acute urinary retention
Introitus bulges with Valsalva maneuver	–	–	–	+
Associated anomalies	Urinary tract and skeletal	Inguinal hernias; gonadal malignancy in adulthood	Major urinary tract abnormalities in 15%	Possibly some increase in urinary tract abnormalities
Treatment	Vaginal dilation or surgical neovagina	Gonadectomy after age 16-18 yr Vaginal dilation or surgical neovagina	Surgical approach depends on extent and location of septum; may be extensive; should be done as soon as possible	Excision of hymen as soon as possible; diagnostic needle aspiration contraindicated because of risk of infection
Fertility	Advanced reproductive technology required; in vitro fertilization surrogate with uterus to gestate pregnancy	Not fertile	Variable, low septa have a better prognosis than do high septa	Usually fertile

+, Present; –, absent; ±, may be present or absent.
*Cervix not visible on pelvic examination. Short vagina; may be absent or obstructed.
†Data from Reindollar RH, Byrd JR, McDonough PG: Delayed sexual development: a study of 252 patients, *Am J Obstet Gynecol* 140:371, 1981.
‡Sometimes useful in differentiating Müllerian agenesis from androgen insensitivity.
From Kliegman RM et al: *Practical strategies in pediatric diagnosis and therapy,* ed 2, Philadelphia, 2004, Elsevier.

3. Pituitary adenomas may be associated with headache, vomiting, vision changes
4. Galactorrhea

- Sheehan syndrome
  1. History of secondary amenorrhea following postpartum hemorrhage
  2. Failure of lactation
  3. Other features of hypopituitarism
- Asherman syndrome
  1. History of D&C
  2. Secondary amenorrhea
  3. Recurrent miscarriage/infertility
- Functional hypothalamic disorders
  1. Usually presents with secondary amenorrhea
  2. History of eating disorders, severe exercise or stress
  3. Use of street drugs
- Kallmann syndrome
  1. Usually presents with anosmia, congenital defect of development of both the GnRH neurons and olfactory placode

DX DIAGNOSIS

- First step in the workup of amenorrhea is to rule out pregnancy by serum/urine pregnancy test.
- Diagnostic workup depends on history and physical (Fig. E1).
- Physical examination, determining the presence or absence of advanced breast Tanner stage and presence or absence of uterus can help guide evaluation (e.g., presence of breasts but absence of uterus can only be Müllerian agenesis or androgen insensitivity syndrome).
- Primary amenorrhea:
  1. Pelvic ultrasonography or MRI to detect any anatomic abnormalities of uterus, cervix, ovaries, or vagina.
  2. Karyotyping (46,XX in Müllerian agenesis; 46,XY in AIS; 45,XO in Turner syndrome) is done when uterus is absent or Turner syndrome is suspected.
  3. Serum FSH, thyroid-stimulating hormone [TSH]/FT4, prolactin, estradiol:
     a. FSH 40 mIU/ml along with estradiol <20 pg/ml is indicative of primary ovarian insufficiency.
     b. Prolactin >200 ng/ml is suggestive of prolactinoma. Threshold levels may vary by laboratory, and providers are advised to become familiar with their institution's normal range.

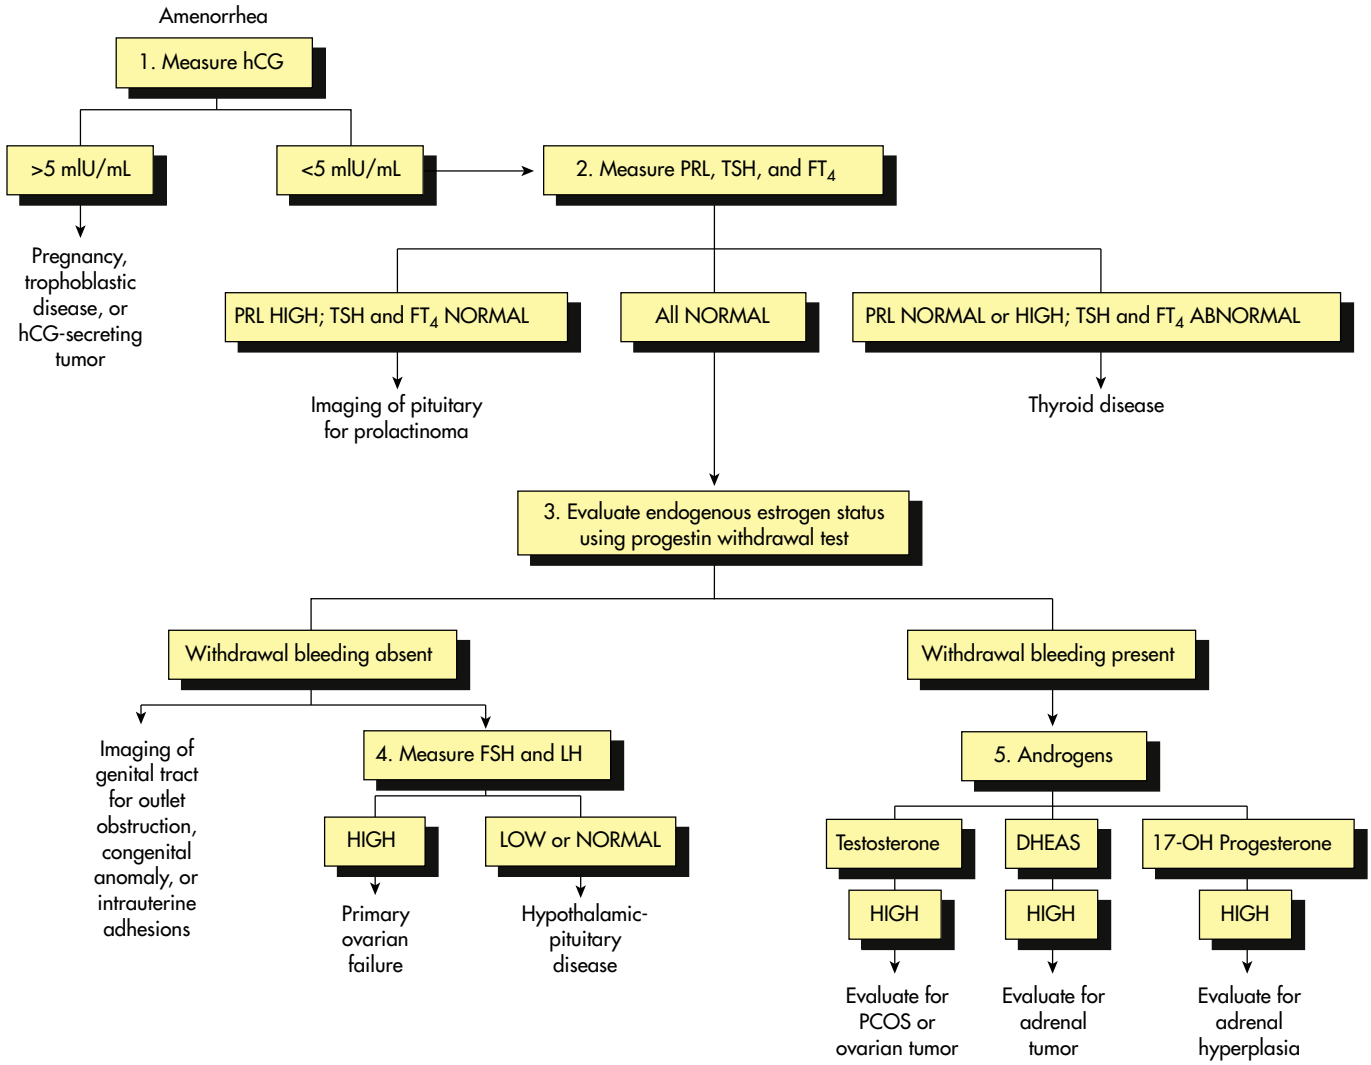

FIG. E1 A diagnostic algorithm for amenorrhea. *DHEAS,* Dehydroepiandrosterone sulfate; *FSH,* follicle stimulating hormone; *FT_4,* free thyroxine; *hCG,* human chorionic gonadotropin; *LH,* luteinizing hormone; *PCOS,* polycystic ovary syndrome; *PRL,* prolactin; *TSH,* thyroid stimulating hormone. (From McPherson RA, Pincus MR: *Henry's clinical diagnosis and management by laboratory methods,* ed 23, Philadelphia, 2017, Elsevier.)

4. Check serum testosterone (male range in AIS; female range in Müllerian agenesis) when uterus is absent or in presence of features of hyperandrogenism.
5. 17-alpha hydroxyprogesterone level in presence of features of hyperandrogenism to rule out CAH. In addition to high level of 17 alpha hydroxyprogesterone due to compromised 21-hydroxylase activity, these patients may have elevated level of serum progesterone and deoxycorticosterone, hypernatremia, and hypokalemia.
6. MRI of head in presence of:
   a. Hyperprolactinemia.
   b. Visual field defects.
   c. Signs of hypothalamic pituitary dysfunction.

- Secondary amenorrhea:
  1. Serum FSH, TSH/FT4, prolactin, estradiol:
     a. Low serum FSH with low estradiol indicates hypogonadotropic hypogonadism.
     b. High serum FSH with low estradiol suggests hypergonadotropic hypogonadism.
  2. Progesterone withdrawal bleeding.
     a. 10 mg medroxyprogesterone is given for 10 days.
     b. Withdrawal bleeding suggests eustrogenic anovulation in presence of normal end organ (outflow tract) and ovarian function.
  3. Estrogen-progesterone withdrawal bleeding:
     a. In the absence of progesterone withdrawal bleeding, the patients are exposed to 25 to 35 days of estrogen (0.625 to 2.5 mg Premarin daily) followed by 10 days of medroxyprogesterone.
     b. Withdrawal bleeding indicates hypogonadism.
     c. Absence of bleeding suggests defects with end organ (e.g., Asherman syndrome).
  4. Serum LH, testosterone and DHEA-S:
     a. When features of hyperandrogenism are seen these tests are ordered.
     b. Serum testosterone >200 ng/ml suggests androgen-producing adrenal or ovarian tumors (high index of suspicion with moderate elevation; threshold value not required in cases of ovarian or adrenal tumors). This level may be mildly elevated in patients with PCOS.
     c. DHEA-S >700 mcg/dl suggests adrenal origin over ovarian (high index of suspicion with moderate elevation; threshold value not required in cases of ovarian or adrenal tumors).
     d. LH/FSH ratio >2 may be present in patients with PCOS, although this is not part of diagnostic criteria according to the Rotterdam consensus conference.
  5. Imaging:
     a. Pelvic ultrasound when PCOS or ovarian tumor suspected.
     b. Abdominal CT when adrenal tumor suspected.
     c. MRI of head when indicated.
     d. HSG, sonohysterography, or diagnostic hysteroscopy in patients with suspected Asherman syndrome.
  6. Other tests which are rarely needed:
     a. Serum transferrin when hemochromatosis is suspected.

b. Serum ACE when sarcoidosis is suspected.
c. Karyotyping is indicated when primary ovarian insufficiency occurs before the age of 40.

Rx TREATMENT

- The treatment of amenorrhea depends on the etiology, as well as the aims of the patient, such as a desire to treat hirsutism or to become pregnant.
- Estrogen replacement along with calcium and vitamin D should be instituted in patients with hypogonadism to avoid osteoporosis. Women with a uterus require continuous or intermittent progesterone administration to protect against endometrial hyperplasia or cancer. Often, combination oral contraceptive pills are used.
- Many patients with anatomic abnormalities may require surgical correction. Creation of a new vagina for patients with Müllerian agenesis is usually delayed until the woman is emotionally mature and ready to participate in the serial dilation or postoperative care required to maintain vaginal patency. However, if adequate correction is impossible, pregnancy will often require a surrogate to carry a gestation. Always assess for the associated urogenital anomalies, such as renal agenesis, in these patients and, when present, treat them appropriately.
- In patients with androgen insensitivity syndrome, the incidence of gonadal malignancy is 22%. However, it rarely occurs before the age of 20. Gonadectomy is performed by laparoscopy following breast development and the attainment of adult stature. In the absence of a uterus these individuals only need estrogen replacement without progesterone.
- Women with adult-onset CAH may be treated with low-dose corticosteroids in addition to sex steroids to partially block ACTH stimulation of adrenal function and thereby decrease overproduction of adrenal androgens.
- Patients with primary ovarian insufficiency (POI) will need estrogen and progesterone replacement. These patients will require in vitro fertilization using donor oocytes to conceive. These patients have an increased risk of osteoporosis and heart disease. It can also be associated with autoimmune disorders such as hypothyroidism, Addison disease, and diabetes mellitus. Therefore, fasting blood glucose, TSH, and, if clinically appropriate, morning cortisol should be measured. In the presence of a Y chromosome, removal of gonadal tissue is recommended at the time of diagnosis to avoid gonadal tumors.
- Hypothyroidism should be treated with thyroid replacement.
- Hyperprolactinemia is treated by avoiding the culprit drugs or by giving dopamine agonists, such as bromocriptine or cabergoline. Pituitary adenomas rarely require surgery but surgery may be performed if secondary deficits such as visual changes are observed, when they are resistant to medical therapy, or the lesion is rapidly growing.
- Treatment of hypothalamic amenorrhea depends on the etiology. Patients with eating disorders or who exercise excessively will require behavioral modification and nutritional counseling. Elite athletes may choose not to alter their exercise regimens and will therefore require estrogen treatment and prevention of osteoporosis. When associated with infertility, ovulation induction with clomiphene citrate, exogenous gonadotropins, or pulsatile GnRH therapy should be offered.
- The primary treatment of PCOS is weight loss through diet and exercise. Other treatment options include:
  1. Use of oral contraceptive pills or cyclic progestational agents to help maintain a normal endometrium.
  2. Insulin-sensitizing agents such as metformin to reduce insulin resistance and improve ovulatory function. Recent studies suggest that insulin-sensitizing agents may not be as effective in improving ovulatory effort.
  3. Oral contraceptives and/or spironolactone to treat hyperandrogenism.
  4. Clomiphene citrate or an aromatase inhibitor such as letrozole to induce ovulation.
- In patients with Asherman syndrome, hysteroscopic lysis of intrauterine adhesions is followed by administration of long-term exogenous estrogen to stimulate regrowth of endometrial tissue.
- Geneticist consult is given in patients with hereditary causes of amenorrhea.
- Psychiatrist consult is needed in patients with major depression, anorexia nervosa, bulimia nervosa, or other major psychiatric disorders.

COMPLICATIONS

- Osteoporosis
- Endometrial hyperplasia and uterine cancer
- Infertility

PROGNOSIS

Depends on the etiology of amenorrhea.

PATIENT & FAMILY EDUCATION

- Patients with amenorrhea should be reassured that this is, in and of itself, not a concern.
- All women with an intact endometrium should understand the risks of unopposed estrogen action, whether the estrogen is exogenous such as through hormone therapy, or endogenous such as PCOS.
- Hypoestrogenic women should be counseled about the importance of estrogen replacement to protect against bone loss.
- Potential for future childbearing should be discussed.

BASIC INFORMATION

DEFINITION

The term *amyloidosis* refers to a heterogeneous group of disorders (Table E1) that are all characterized by the deposition of an amorphous, extracellular fibrillar protein in various organs and tissues of the body (Table E2). It has the following subtypes:

- Primary amyloidosis (AL)
- Secondary amyloidosis (AA)
- Hereditary amyloidosis
- Localized amyloidosis

ICD-10CM CODES

E85.9 Amyloidosis, unspecified
E85.0 Non-neuropathic heredofamilial amyloidosis
E85.1 Neuropathic heredofamilial amyloidosis
E85.2 Heredofamilial amyloidosis, unspecified
E85.3 Secondary systemic amyloidosis
E85.4 Organ-limited amyloidosis
E85.8 Other amyloidosis

TABLE E1 Nomenclature of Amyloidosis

Protein	Precursor	Clinical Characteristics
AL or AH	Immunoglobulin light or heavy chain	Primary or localized; myeloma or macroglobulinemia associated
AA	SAA	Secondary or familial Mediterranean fever, familial periodic fever syndromes
ATTR	Transthyretin	Familial and senile
A fibrinogen	Fibrinogen	Familial renal amyloidosis (Ostertag type)
$A\beta_2M$	β_2-Microglobulin	Dialysis associated; carpal tunnel syndrome
$A\beta$	ABPP	Alzheimer disease
A Apo A-I/A-II	Apolipoprotein A-I	Proteinuria
	Apolipoprotein A-II	Cardiac
		Neuropathy
A lysozyme	Lysozyme	GI tract
		Liver
		Renal
ALECT2	Renal	

AA, Amyloid A; *Aβ,* amyloid-β; *ABPP,* amyloid-β precursor protein; *$A\beta_2M$,* β_2-microglobulin-related amyloid; *AH,* amyloid heavy chain; *AL,* amyloid light chain; *ALECT2,* leukocyte chemotactic factor 2 amyloidosis; *Apo,* apolipoprotein; *ATTR,* transthyretin-related hereditary amyloidosis; *GI,* gastrointestinal; *SAA,* serum amyloid A.
Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Between 1500 and 3500 new cases are diagnosed annually. The most common type is AL.

PREVALENCE: Amyloidosis primarily affects men between the ages of 60 and 70 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The most common presenting symptoms of amyloidosis are fatigue, dyspnea, edema, paresthesias, and weight loss. Other findings depend on organ system involvement. Syndromes in primary amyloidosis are summarized in Table E3.
- Signs and symptoms of nephrotic syndrome may be present with renal involvement.
- Fatigue and dyspnea may occur with pulmonary involvement.
- GI involvement is uncommon but presents with diarrhea, nausea, abdominal pain, and macroglossia (Fig. E1).
- Patients with cardiac involvement have an infiltrative cardiomyopathy and present with a preserved ejection fraction (EF) and diastolic dysfunction.
- Patients may present with bleeding problems caused by either factor X deficiency or fragile blood vessels caused by infiltration by amyloid. Bleeding around the eyes (raccoon eyes) is a characteristic finding (Fig. E2).
- Involvement of the nervous system presents with peripheral neuropathy, tendinopathy (Fig. E3), muscle weakness, numbness, syncope, or dizziness. Associated autonomic neuropathy can also cause severe disabling symptoms.

ETIOLOGY

The deposition of an amorphous, extracellular fibrillar protein in various tissues that stains with Congo red is the common underlying mechanism, but there are important differences among various subtypes:

- AL is associated with an underlying clonal plasma cell disorder making an abnormal light chain protein with possible deposition in multiple organ systems.
- AA has no underlying plasma cell disorder and is a consequence of longstanding systemic inflammation (e.g., tuberculosis, leprosy, malaria, untreated syphilis).
- Localized amyloidosis results from localized synthesis of fibrillar material with no underlying plasma cell disorder.
- Familial amyloidosis is another subtype, with the most common form resulting from mutation of transthyretin gene (TTR). Transthyretin amyloidosis is caused by the deposition of hepatocyte-derived transthyretin amyloid in peripheral nerves and the heart.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential diagnosis varies depending on the organ involvement:

- Renal involvement (toxin- or drug-induced necrosis, glomerulonephritis, renal vein thrombosis)
- Interstitial lung disease (sarcoidosis, connective tissue disease, infectious causative factors)
- Restrictive cardiomyopathy (endomyocardial fibrosis, viral myocarditis)
- Carpal tunnel (rheumatoid arthritis, hypothyroidism, overuse)
- Peripheral neuropathy (alcohol abuse, vitamin deficiencies, diabetes mellitus)

WORKUP

Workup consists of performing blood and urine tests to look for abnormal light chain in urine or blood, performing various tests to look for target organ damage, and getting histologic confirmation by doing a fat pad and bone marrow biopsy and then performing Congo red staining (Fig. E4) on that. Box E1 summarizes recommended diagnostic evaluation for amyloidosis. Fig. E5 describes an algorithm for diagnosis of amyloidosis. Amyloid staging is described in Box E2.

LABORATORY TESTS

- Immunofixation of serum and urine (serum protein electrophoresis [SPEP], urine protein electrophoresis [UPEP]) to look for immunoglobulin light chain is a sensitive screening test.
- CBC, blood urea nitrogen (BUN)/creatinine, liver function tests, thyroid functions, and urine for albumin.
- Histologic confirmation is necessary with a fat pad and bone marrow biopsy with Congo red staining to establish a diagnosis.
- If a noninvasive fat pad biopsy does not establish a diagnosis, then a biopsy of the affected organ may be needed.

IMAGING STUDIES

- Cardiac MRI has a distinctive pattern.
- Two-dimensional Doppler echocardiography to study diagnostic filling is useful to evaluate for cardiac involvement but is not as sensitive as cardiac MRI.
- Nuclear imaging with technetium-labeled aprotinin may detect cardiac amyloidosis. Labeled diphosphonates play an important role in the typing of amyloidosis and in diagnosing heart involvement in patients with transthyretin cardiac amyloidosis.

TABLE E2 Classification of Amyloidosis*

Type	Fibril Precursor Protein	Clinical Syndrome
AA	Serum amyloid A protein	Systemic amyloidosis usually with predominantly renal involvement associated with acquired or hereditary chronic inflammatory diseases. Formerly known as *secondary* or *reactive amyloidosis.*
AL	Monoclonal immunoglobulin light chains	Systemic amyloidosis potentially involving many organ systems associated with myeloma, monoclonal gammopathy, and occult B-cell dyscrasias. Formerly known as *primary amyloidosis.*
ATTR	Normal plasma transthyretin	Wild-type (nonhereditary) systemic amyloidosis with predominantly cardiac involvement (formerly known as *senile cardiac amyloidosis*).
ATTR	Genetic variants of transthyretin (e.g., ATTR Met30, Ala60, Ile122)	FAP, often with prominent amyloid cardiomyopathy. Predominantly cardiac involvement without neuropathy with certain mutations (e.g., TTR Ile122).
$A\beta_2M$	β_2-Microglobulin	Dialysis-related amyloidosis associated with renal failure and long-term dialysis. Predominantly articular and periarticular involvement.
$A\beta$	β-Protein precursor (and rare genetic variants)	Cerebrovascular and intracerebral plaque amyloid in Alzheimer disease. Occasionally familial.
AApoAI	Genetic variants of apolipoprotein AI (e.g., AApoAI Arg26, Arg60)	Autosomal dominant systemic amyloidosis. Predominantly nonneuropathic with prominent visceral involvement, especially nephropathy. Minor wild-type apolipoprotein AI amyloid deposits may occur in the aorta in aging individuals.
AApoAII	Genetic variants of apolipoprotein AII	Autosomal dominant systemic amyloidosis with predominantly renal involvement.
AFib	Genetic variants of fibrinogen A α chain (e.g., AFib Val526)	Autosomal dominant systemic amyloidosis. Nonneuropathic with predominant nephropathy.
ALys	Genetic variants of lysozyme (e.g., ALys His67)	Autosomal dominant systemic amyloidosis. Nonneuropathic with predominantly renal and GI involvement. Rarely presents with hepatic rupture.
ACys	Genetic variant of cystatin C (ACys Gln68)	Hereditary cerebral hemorrhage with cerebral and systemic amyloidosis in Icelandic individuals.
AGel	Genetic variants of gelsolin (e.g., AGel Asn187)	Autosomal dominant systemic amyloidosis. Predominantly cranial nerve involvement plus lattice corneal dystrophy. Described and most common in Finland.

FAP, Familial amyloid polyneuropathy; *GI,* gastrointestinal.
*Not exhaustive and amyloid composed of peptide hormones, prion protein, and unknown proteins not included.
Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

TABLE E3 Syndromes in Primary Amyloidosis

Syndrome	Patients (%)
Nephrotic or nephrotic and renal failure	30
Hepatomegaly	24
Congestive heart failure	22
Carpal tunnel	21
Neuropathy	17
Orthostatic hypotension	12

From Hoffman R: *Hematology: Basic principles and practice,* ed 7, 2018, Elsevier.

Cardiac involvement in transthyretin patients may be diagnosed earlier with bone scintigraphy in transthyretin patients compared with echocardiography. Serum amyloid P component (SAP) scintigraphy has high sensitivity for the detection of amyloid deposits in liver, spleen, kidneys, adrenal glands, and bones.

FIG. E1 Macroglossia in a patient with primary amyloidosis, demonstrating peripheral ridging caused by teeth indentation. (From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

Rx TREATMENT

ACUTE GENERAL RX

- Patients with AL amyloidosis should be evaluated for autologous hematopoietic stem cell transplantation (HSCT). Patients with good performance status, age under 70 and limited organ involvement are good candidates.
- The goal of chemotherapy is to decrease the production of the amyloidogenic light chain with therapy directed at the clonal plasma cells.
- All agents used to treat multiple myeloma are effective against AL, including melphalan, and prednisone. Immunomodulatory compounds (IMiDs) such as thalidomide or lenalidomide, or proteasome inhibitors are also effected. Patients ineligible for autologous HSCT should receive chemotherapy with melphalan- or bortezomib-based

FIG. E2 Classic amyloid purpura. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

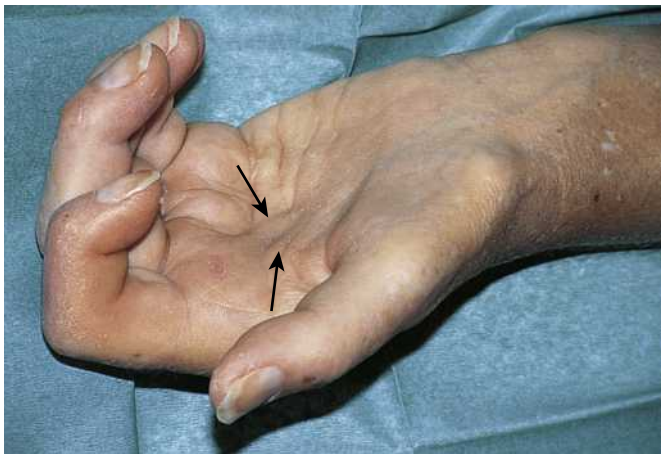

FIG. E3 Hand involvement in Aβ_2M amyloidosis. Hand of a long-term hemodialysis patient showing maximal extension. Note the prominence of shrunken flexor tendons *(arrows).* This is also known as the "guitar string" sign. (From Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, Saunders.)

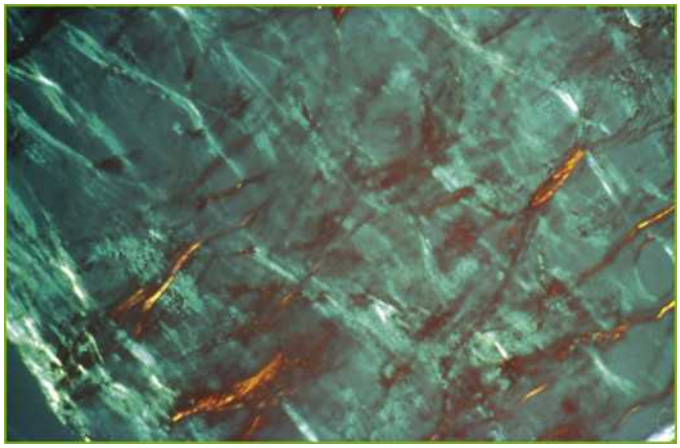

FIG. E4 Fat aspiration. (Congo red stain; original magnification, ×1000.) Note preserved fat cell interstices. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

BOX E1 Recommended Diagnostic Evaluation for Amyloidosis

- CBC
- Sodium, potassium, alkaline phosphatase, calcium, phosphorus, AST, bilirubin, creatinine, β_2-microglobulin, glucose, cholesterol, uric acid, thyroid profile
- Immunofixation; serum; immunofixation urine; nephelometric assay if immunoglobulin free light chains; immunoglobulins G, A, and M
- Troponin, NT-proBNP
- Factor X and prothrombin time
- Chest x-ray, ECG, echocardiogram with Doppler and strain imaging

AST, Aspartate aminotransferase; *ECG,* electrocardiogram; *NT-proBNP,* N-terminal pro b-type natriuretic peptide.
Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

regimens. Table E4 summarizes major treatment options for amyloidosis.
- Trials with oligonucleotide drugs (inotersen, patisiran) have shown improved multiple clinical manifestations of hereditary transthyretin amyloidosis.
- Patients who develop renal failure can be supported with hemodialysis or renal transplant.
- Liver transplantation has been used successfully in patients with familial amyloidosis.
- Recognition and treatment of the underlying disorder is needed for secondary amyloidosis.
- Table E5 summarizes supportive treatment options for all types of amyloidosis.

DISPOSITION

Prognosis is determined primarily by the presence or absence of cardiac involvement and the form of amyloidosis:
- In patients with endomyocardial biopsy–documented cardiac amyloidosis, longer-term survival is more strongly associated with New York Heart Association functional class compared with ECG or echocardiography variables.
- In AA, eradication of the predisposing disease slows and can occasionally reverse the progression of amyloid disease. Median survival after diagnosis is 133 mo.
- Patients with familial amyloidotic polyneuropathy generally have a prolonged course lasting 10 to 15 yr.
- The progression of amyloidosis associated with renal hemodialysis can be improved with newer dialysis membranes that can pass beta 2-microglobulin.
- Median survival in patients with overt congestive heart failure (CHF) is ~6 mo; it is 30 mo without CHF.

AUTHOR: **Fred F. Ferri, MD**

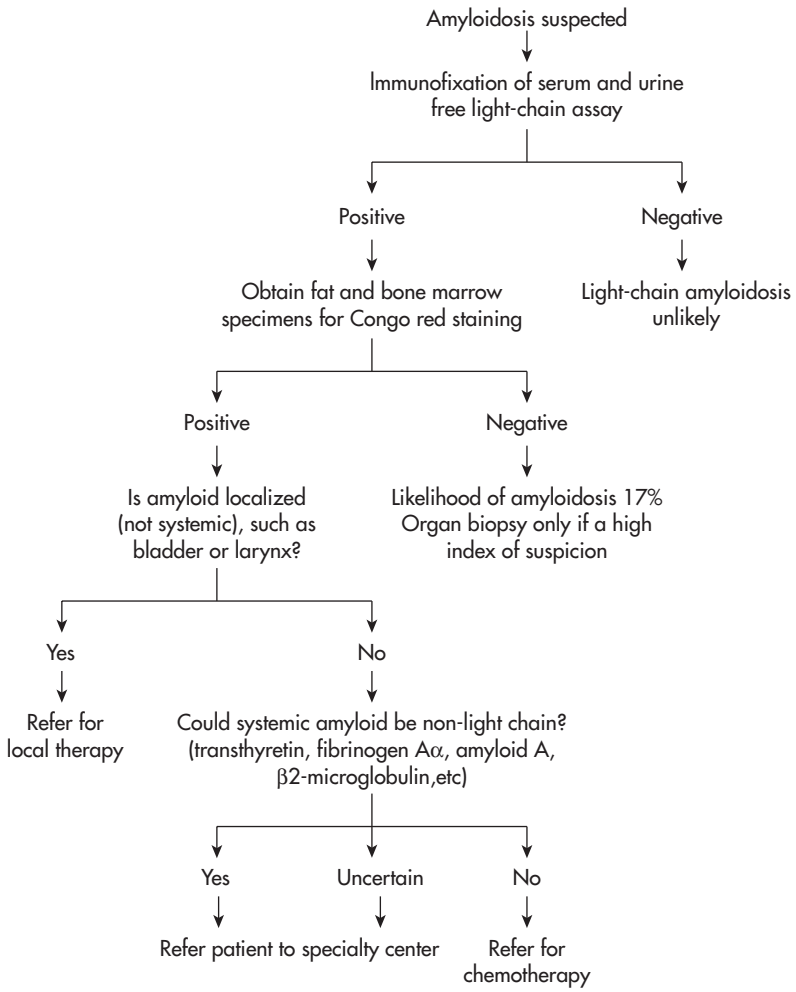

FIG. E5 Diagnostic algorithm for use when amyloidosis is suspected. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

BOX E2 Amyloid Staging

Patients are assigned a score of 1 point for each of the following:
- FLC-diff ≥18 mg/dl
- cTnT ≥0.025 ng/ml
- NT-proBNP ≥1800 pg/ml

This creates stages I–IV with scores of 0–3 points, respectively
Median survival (months):
- 94.1
- 40.3
- 14
- 5.8

1. Difference between the involved and uninvolved serum light chain levels
2. Cardiac troponin T
3. N-terminal pro-brain natriuretic peptide

cTnT, Cardiac troponin T; *FLC-diff,* difference between involved and uninvolved free light chains; *NT-proBNP,* N-terminal pro-B-type natriuretic peptide
Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE E4 Major Treatment Options for Amyloidosis

AL Amyloidosis

Intravenous melphalan with autologous stem cell rescue
- Granulocyte colony-stimulating factor–mobilized peripheral blood stem cell collection
- Intravenous melphalan 140-200 mg/m^2
- Autologous stem cell reinfusion

Cyclic oral melphalan and dexamethasone
- Melphalan 0.22 mg/kg/day × 4 days
- Dexamethasone 20-40 mg/day × 4 days, or weekly
- Repeat administration every 4 weeks

Immunomodulators
- Lenalidomide 5-15 mg/day × 21 days
- Dexamethasone 20-40 mg/day weekly
- Repeat administration every 4 weeks

Proteasome inhibitors
- Intravenous bortezomib, 0.7-1.6 mg/m^2 1-2 times per week
- Repeat every 3-5 weeks

AA Amyloidosis
- Aggressive treatment of underlying inflammatory disease
- Medical or surgical treatment of underlying infection
- Colchicine 1.2-1.8 mg/day for AA amyloidosis secondary to familial Mediterranean fever
- Antifibril drug, eprosidate (investigational)

ATTR Amyloidosis
- Orthotopic liver transplantation
- Transthyretin stabilizers: Tafamidis, diflunisal (investigational)
- Oligonucleotide drugs: Inotersen, patisiran (investigational)

AA, Primary amyloidosis; *AL,* secondary amyloidosis; *ATTR,* transthyretin-related hereditary amyloidosis.
Modified from Firestein GS et al: *Kelly's textbook of rheumatology,* ed 9, Philadelphia, 2013, Saunders.

TABLE E5 Supportive Treatment for All Types of Amyloidosis

Organ System	Symptom	Treatment Options
Cardiac	Congestive failure	Salt restriction of 1-2 g/day
		Diuretics: Furosemide, spironolactone, metolazone
	Arrhythmia	Pacemaker
		Automatic implantable cardiac defibrillator
		Antiarrhythmics
Renal	Nephrotic syndrome	Salt restriction of 1-2 g/day
		Elastic stockings, leg elevation
		Maintaining dietary protein
		Angiotensin-converting enzyme inhibitor, if blood pressure tolerates
	Renal failure	Dialysis (long-term ambulatory peritoneal dialysis or hemodialysis)
Autonomic nervous	Orthostatic hypotension	Midodrine
		Increased dietary salt or added fludrocortisone, depending on edema
		Elastic stockings
	Gastric atony or ileus	Small frequent feedings (6/day) low in fat
		Oral nutritional supplements
		Jejunostomy tube feeding
		Parenteral nutrition
Gastrointestinal	Diarrhea	Low-fat diet (≤40 g)
		Psyllium hydrophilic mucilloid (Metamucil)
		Loperamide hydrochloride (Imodium)
		Tincture of opium
		Parenteral nutrition
	Macroglossia	Soft solid diet
		Partial glossectomy (rarely effective)
Peripheral nervous	Sensory neuropathy	Avoiding trauma
		Gabapentin (Neurontin) 100-300 mg 3 times daily
		Amitriptyline 25-50 mg at bedtime
		Pregabalin (Lyrica) 50-100 mg 3 times daily
	Motor neuropathy	Ankle-foot orthotics for footdrop
		Physical therapy
Hematologic	Intracutaneous bleeding	Avoiding trauma, antiplatelet agents
	Factor X deficiency	Factor replacement (recombinant factor VIIa, prothrombin complex concentrates)
		Splenectomy for splenomegaly

BASIC INFORMATION

DEFINITION

Amyotrophic lateral sclerosis (ALS) is a progressive and fatal degenerative neuromuscular condition of undetermined etiology affecting corticospinal tracts and anterior horn cells, thereby resulting in dysfunction of both upper motor neurons (UMNs) and lower motor neurons (LMNs).

SYNONYMS

Lou Gehrig disease
ALS

ICD-10CM CODE
G12.21 Amyotrophic lateral sclerosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Two new cases per 100,000 persons per yr.
- Onset is usually between the ages of 50 and 70 yr.
- Male:female ratio is 1.8:1.

PREVALENCE: The estimated prevalence of ALS is 5.2 per 100,000 population. Whites, males, and Hispanics, persons aged ≥60 yr, and those with a family history of ALS are more likely to develop the disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- LMN signs (weakness, hypotonia, muscle wasting, fasciculations, hyporeflexia or areflexia).
- UMN signs (loss of fine motor dexterity, spasticity, extensor plantar responses, hyperreflexia, clonus).
- Preservation of extraocular movements, sensation, bowel and bladder function.
- Dysarthria, dysphagia, pseudobulbar affect, frontal lobe dysfunction.
- Respiratory insufficiency progressing to respiratory failure and death typically occurs late in the disease.
- Concomitant frontotemporal dementia in 15% and executive dysfunction in another 50%.
- Pseudobulbar affect, characterized by inappropriate crying or laughing not provoked by typical emotional triggers, is common and treatable.
- ALS comprises approximately 90% of adult-onset motor neuron diseases. Other presentations of motor neuron disease include progressive muscular atrophy, primary lateral sclerosis, progressive bulbar palsy, progressive pseudobulbar palsy, and ALS-parkinsonism-dementia complex.

ETIOLOGY

- 90% to 95% of all cases are sporadic. 5% to 10% of cases are familial; known genetic mutations include C9orf72 hexanucleotide repeat expansion (chromosome 9 open reading frame 72), responsible for 40% of familial ALS and 7% of sporadic ALS (and virtually all cases of ALS associated with frontotemporal dementia); copper-zinc superoxide dismutase enzyme (SOD1) mutations (12% of familial cases), TAR DNA-binding protein mutations (4% of familial cases), FUS (4% of familial cases and rarely associated with frontotemporal dementia), among many others.
- Increased risk factors in whites, non-Hispanics, age >60 yr, family history of ALS, previous exposure to heavy metals, pesticides, BMAA.[1]

[1]Mehta P et al: Prevalence of ALS in USA, 2012–2013, *MMWR* 65(8), 2016.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Multifocal motor neuropathy with conduction block
- Cervical spondylotic myelopathy with polyradiculopathy
- Spinal stenosis with compression of lumbosacral nerve roots
- Chronic inflammatory demyelinating polyneuropathy with central nervous system lesions
- Syringomyelia
- Syringobulbia
- Foramen magnum tumor
- Meningeal carcinomatosis
- Spinal muscular atrophy
- Polyglucosan body disease
- Bulbospinal muscular atrophy (Kennedy disease)
- Monomelic amyotrophy
- Lyme disease
- ALS-like syndromes have been reported in the setting of lead intoxication, HIV, hyperparathyroidism, hyperthyroidism, lymphoma, and vitamin B_{12} deficiency.

WORKUP

- Diagnosis is based on clinical findings, EMG results, and exclusion of alternative causes.
- MRI of brain and spine to exclude alternative causes
- Electromyography and nerve conduction studies (El Escorial criteria; see Table E1)
- Assessment of respiratory function (forced vital capacity [FVC], negative inspiratory force)
- Assessment of swallowing ability and nutritional status

TABLE E1 Revised El Escorial Diagnostic Criteria for Amyotrophic Lateral Sclerosis (ALS)

The Diagnosis of ALS Requires:

- [A:1] Evidence of LMN degeneration by clinical, electrophysiologic, or neuropathologic examination
- [A:2] Evidence of UMN degeneration by clinical examination and
- [A:3] Progressive spread of symptoms or signs within a region or to other regions, as determined by history or examination

Together with the Absence of:

- [B:1] Electrophysiologic and pathologic evidence of another disease that might explain the signs of LMN and/or UMN degeneration and
- [B:2] Neuroimaging evidence of other disease processes that might explain the observed clinical and electrophysiologic signs

Levels of Diagnostic Certainty:

Definite ALS
- UMN signs and LMN signs in 3 regions

Probable ALS
- UMN signs and LMN signs in 2 regions with UMN signs rostral to LMN signs

Probable ALS—Laboratory Supported
- UMN signs in 1 or more regions *and* LMN signs defined by EMG in at least 2 regions

Possible ALS
- UMN signs and LMN signs in 1 region (together) or
- UMN signs in 2 or more regions
- UMN and LMN signs in 2 regions with *no* UMN signs rostral to LMN signs

EMG, Electromyography; *LMN,* lower motor neuron; *UMN,* upper motor neuron.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

LABORATORY TESTS

- Vitamin B_{12}, thyroid function, parathyroid hormone, HIV may be considered
- Serum protein electrophoresis with immunofixation
- Consider DNA studies for spinal muscular atrophy, bulbospinal atrophy (Kennedy disease), hexosaminidase levels (late onset Tay Sachs) in a pure LMN syndromes
- 24-hour urine for heavy metals if indicated
- Genetic studies in familial ALS with appropriate genetic counseling

IMAGING STUDIES

- Craniospinal neuroimaging contingent on clinical scenario. MRI of the brain and spinal cord are useful to help exclude structural mimics.
- Modified barium swallow to evaluate aspiration risk.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Bilevel positive airway pressure (BiPAP) ventilation may improve quality of life and may increase tracheostomy-free survival in patients with respiratory difficulty (defined by orthopnea or FVC 50% of predicted).
- Percutaneous endoscopic gastrostomy (PEG) tube placement improves nutritional intake, promotes weight stabilization, and eases medication administration. Some studies suggest PEG placement may prolong life 1 to 4 mo, particularly when placed before FVC falls to ≤50% of predicted value.
- Nutrition, speech therapy, physical and occupational therapy services.
- Suction device for sialorrhea.
- Cough assist device for ineffective coughing and maintaining a clear airway.
- Communication may be eased with computerized assistive devices.
- Early discussion of living will, resuscitation orders, desire for PEG and tracheostomy, potential long-term care options.
- Encourage contact with local support groups.

ACUTE GENERAL Rx

- Treatments currently available, riluzole and edaravone, do not cure ALS but slow disease progression in certain patients.
- Riluzole, a glutamate antagonist, was the first FDA-approved medication known to extend tracheostomy-free survival in patients with ALS. Dosage is 50 mg q12h, at least 1 hr before or 2 hr after meals. It is shown to prolong survival by 2 to 3 months. Manufacturer recommends checking alanine aminotransferase (ALT) once a month for 3 months initially, followed by once every 3 months until the first yr of therapy is completed. ALT should be checked periodically thereafter.
- Edaravone was FDA approved in 2017 and was found to slow down physical decline by 33% compared with placebo in a phase III trial lasting 6 months. It is administered intravenously, requiring an initial cycle of daily infusions for 14 consecutive days, followed by 14 days without infusion. Subsequent treatment cycles require ten infusions over 14 days, followed by 14 days without infusions. Cost is a factor, and insurance coverage is variable.

CHRONIC Rx

- Sialorrhea may respond to either glycopyrrolate or amitriptyline (consider either propranolol or metoprolol if secretions are thick). Botulinum toxin may be effective in medically refractory cases.
- Spasticity may be treated pharmacologically with baclofen, tizanidine, clonazepam.
- Pseudobulbar affect may improve with amitriptyline, sertraline, or dextromethorphan/quinine.

DISPOSITION

- Currently there is no cure for ALS.
- Mean duration of symptoms is 3 to 5 yr.
- Approximately 20% of patients survive >5 yr.

REFERRAL

- A neurologist experienced in neuromuscular disease is recommended to confirm the diagnosis. One prospective, population-based study suggested improved survival in subjects treated in a multidisciplinary ALS clinic.
- Gastroenterology referral for PEG placement is recommended while FVC remains >50% to minimize morbidity attributable to risks inherent to the procedure.
- Pulmonology referral for bilevel positive pressure airway ventilation (BiPAP).

PEARLS & CONSIDERATIONS

- Patient-physician communication is an integral and essential part in both the initial diagnosis and subsequent treatment of ALS.
- A multidisciplinary approach to supportive care may lead to an improved level of daily functioning and foster an increased sense of independence.

Amyotrophic Lateral Sclerosis (Patient Information)

AUTHORS: **Taylor Harrison, MD,** and **Joseph S. Kass, MD, JD, FAAN**

BASIC INFORMATION

DEFINITION

An anaerobic infection is caused by one of a group of bacteria that requires a reduced oxygen tension for growth.

ICD-10CM CODES

A41.4	Sepsis, anaerobic
A48	Cellulitis, anaerobic

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- May occur at any site, but most are anatomically related to mucosal surfaces
- Should be suspected when there is foul-smelling tissue, soft tissue gas, necrotic tissue, or abscesses
- Head and neck:
  1. Odontogenic infections from dental or soft tissue possibly progressing to periapical abscesses, at times extending to bone
  2. Both anaerobic and aerobic pathogens in chronic sinusitis, chronic mastoiditis, peritonsillar abscess, and chronic otitis media
  3. Complications: Deep neck space infections, brain abscesses, mediastinitis
  4. Specific examples of anaerobic infections in head and neck:
     a. Ludwig angina: Bilateral infection of sublingual and submandibular spaces that causes swelling of the base of the tongue with potential airway compromise. Usually mixed aerobic and anaerobic flora
     b. Lemierre syndrome: Jugular vein suppurative thrombophlebitis caused by anaerobic bacteria: *Fusobacterium necrophorum*
- Pleuropulmonary:
  1. May involve anaerobes present in the oropharynx
  2. Aspiration more common in persons with altered mental status or seizures
  3. Anaerobic bacteria more likely in those with gingivitis or periodontitis
  4. Manifestations: Necrotizing pneumonia, empyema, lung abscess
- Intraabdominal:
  1. Disruption of intestinal integrity leading to infection involving anaerobic bacteria
  2. Bacteria from colonic neoplasm, perforated appendicitis, diverticulitis, or bowel surgery, causing bacteremia, peritonitis, at times intraabdominal abscesses
  3. Resulting infections usually mixed, containing both anaerobes and aerobes
- Female genital tract:
  1. Anaerobes in bacterial vaginosis, salpingitis, endometritis, pelvic abscesses, septic abortion; infections tend to be mixed
  2. Possible pelvic thrombophlebitis when resolving pelvic infection is accompanied by new or persistent fever
- Other anaerobic infections:
  1. Skin and soft tissue infection at any site
  2. More commonly associated infections: Synergistic gangrene, bite wound infections, infected decubitus ulcers
  3. Clinical significance of anaerobes in diabetic foot infections unclear
  4. Anaerobic bacteremia is not common with source usually intraabdominal, followed by female genital tract, pleuropulmonary, and head and neck infections
  5. Osteomyelitis especially when associated with decubitus ulcers or vascular insufficiency
  6. Facial bone osteomyelitis from adjacent infections of the teeth or sinuses

ETIOLOGY

- Most commonly endogenous, arising from bacteria that normally line mucosal surfaces
- Disruption of mucosal barriers resulting from various conditions (trauma, ischemia, surgery, perforation), with infection occurring when organisms gain access to normally sterile sites, causing tissue destruction and abscess formation
- Synergy between different anaerobes or between anaerobes and aerobes important
- Examples of anaerobic bacteria include gram-negative bacteria such as *Bacteroides* species, *Fusobacterium* and *Prevotella* species; and gram-positive bacteria such as *Peptostreptococcus, Clostridium* species, and *Actinomyces* species

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary differential possibility is an aerobic bacterial infection without the presence of anaerobic bacteria.
- Ischemic necrosis without accompanying anaerobic infection (or "dry" gangrene [non-infected necrosis] vs. "wet" gangrene [infected tissue with anaerobic infection]).

WORKUP

- Specimens submitted for anaerobic culture should be processed within 30 min and may take up to 5 to 7 days to grow
- Large volume of material more likely to have significant growth; swabs less efficient for transporting infected material
- Blood cultures—preferably before antibiotic administration

LABORATORY TESTS

- Elevated white blood cell (WBC) count, with extremely high WBC counts sometimes seen with pseudomembranous colitis
- Positive stool *C. difficile* by polymerase chain reaction (PCR) or nucleic acid amplification test (NAAT)
- Increased lactate levels in ischemia or perforation
- Possible positive blood or wound cultures, but failure to grow anaerobes in culture may be common, attributed to inadequate culturing techniques or fastidious organisms

IMAGING STUDIES

- Plain film of an affected area to show gas in tissues, free air resulting from a perforated viscus, or an air/fluid level inside an abscess
- Ultrasound, computed tomography (CT) scan, or MRI to reveal abscesses or tissue destruction

TREATMENT

NONPHARMACOLOGIC THERAPY

- Removal of necrotic tissue
- Drainage of abscesses (accomplished by CT scan–guided percutaneous drainage)

ACUTE GENERAL Rx

Oral antibiotics with anaerobic activity: Clindamycin, metronidazole, and chloramphenicol

- Broader spectrum of activity with amoxicillin/clavulanate
- Penicillin VK in odontogenic infections
- Oral vancomycin is now the preferred agent for *C. difficile*–associated diarrhea, and metronidazole is now considered a second line agent. Use oral vancomycin for subsequent episodes and for pulse or taper regimens of *C difficile*–associated diarrhea treatment

Parenteral antibiotics for more serious illness

- IV clindamycin, metronidazole, and chloramphenicol
- Cephalosporins (with anaerobic or mixed infections coverage): Cefoxitin and cefotetan
- Extended-spectrum penicillins (e.g., piperacillin) and combination beta-lactamase plus beta-lactamase inhibitor drugs (e.g., clavulanic acid, sulbactam, tazobactam)
  1. Significant anaerobic activity, plus various degrees of broad-spectrum coverage
  2. Include ampicillin/sulbactam, ticarcillin/clavulanate, and piperacillin/tazobactam
- Imipenem or other carbapenems, such as meropenem, doripenem, or ertapenem, which are broad-spectrum agents with extensive anaerobic activity
- Actinomycosis treated with penicillin for 6 to 12 mo
- SMX/TMP and fluoroquinolones are generally ineffective, but some newer quinolones (e.g., moxifloxacin) have inhibitory activity against anaerobes

DISPOSITION

It is essential that all necrotic debris be removed when treating an anaerobic infection or it will recur; follow-up is critically important to ensure resolution of the process.

REFERRAL

Refer to a surgeon if drainage is required; infectious disease consultation may be useful in complicated patients or if treatment regimen is failing or slow to respond.

BASIC INFORMATION

DEFINITION

A fissure is a tear in the epithelial lining of the anal canal (i.e., from the dentate line to the anal verge). Acute anal fissures typically heal with conservative management within 6 weeks. Chronic fissures require a more aggressive, surgical approach.

SYNONYMS

Anorectal fissure
Anal ulcer

ICD-10CM CODES

K60.0	Acute anal fissure
K60.1	Chronic anal fissure
K60.2	Anal fissure, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

An estimated 235,000 new cases of anal fissure occur annually in the U.S. Although they can occur at any age, they are more common in infants and middle-aged adults. They occur more in men than women. Women are more likely to have anterior fissure than men (10% vs. 1%, respectively).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

With separation of the buttocks will see a tear in the posterior midline or, less frequently, in the anterior midline

- Acute anal fissure:
  1. Sharp burning or tearing pain accompanying the passage of stool
  2. Bright-red blood on toilet paper, a streak of blood on the stool or in the water
  3. Appear as a fresh laceration (Fig. E1)
- Chronic anal fissure:
  1. Perianal pruritus or skin irritation
  2. Pain less intense or not present
  3. Intermittent bleeding
  4. Sentinel tag at the caudal aspect of the fissure, hypertrophied anal papilla at the proximal end (Fig. E2)
  5. Have raised edges exposing the horizontally oriented fibers of the internal anal sphincter; appearance due to chronic infection and fibrosis
- Atypical fissure can be acute or chronic:
  1. More likely to occur at locations other than the midline
  2. Extends proximal to the dentate line
  3. Unusually wide or deep; multiple, recurring, or nonhealing
  4. Associated with perianal tag that is edematous and tender
  5. More commonly associated with an underlying disease process

ETIOLOGY

- Most initiated after passage of a large, hard stool
- May result from frequent defecation and diarrhea
- Bacterial infections: Tuberculosis (TB), syphilis, gonorrhea, chancroid, lymphogranuloma venereum
- Viral infections: Herpes simplex virus, cytomegalovirus, human immunodeficiency virus
- Inflammatory bowel disease (IBD): Crohn disease, ulcerative colitis
- Trauma: Surgery (hemorrhoidectomy), foreign bodies, anal intercourse
- Malignancy: Carcinoma, lymphoma, Kaposi sarcoma

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Proctalgia fugax
- Thrombosed hemorrhoid
- Carcinoma
- Anal fistula

WORKUP

- Digital rectal examination after lubricating the entire anus with anesthetic jelly (i.e., 2% lidocaine) and waiting 5 to 10 min
- Anoscopy
- Proctosigmoidoscopy to exclude inflammatory or neoplastic disease
- Biopsy if doubt exists about the etiology of the condition
- All studies done under adequate anesthesia

IMAGING STUDIES

- Colonoscopy if diagnosis of IBD or malignancy is suspected
- Small-bowel series occasionally obtained for similar reasons

TREATMENT

NONPHARMACOLOGIC THERAPY

- Sitz baths
- High-fiber diet and increased oral fluid intake

ACUTE GENERAL Rx

- Bulk-producing agent (e.g., Metamucil) and/or stool softener

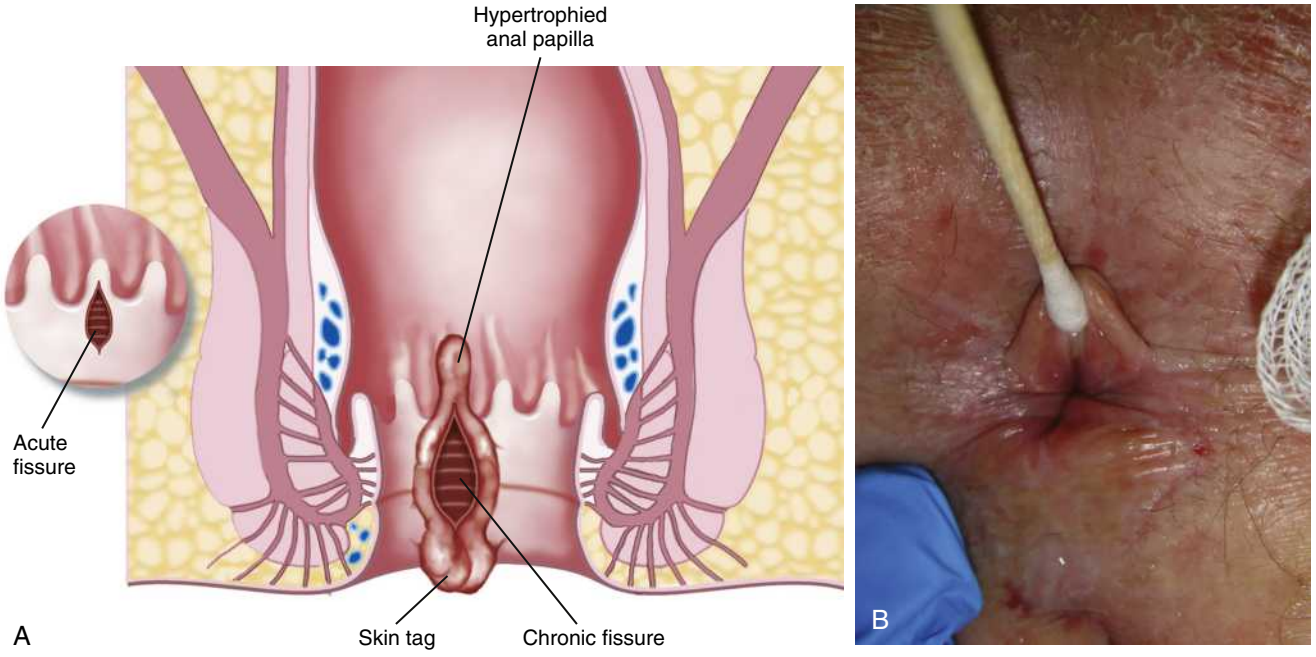

FIG. E1 A, Schematic depiction of acute and chronic anal fissures. An acute fissure is simply a split in the anoderm *(inset).* A chronic fissure can show signs of chronicity with rolled edges, fibrosis, a hypertrophied anal papilla proximally, a tender distal skin tag, and exposed internal anal musculature. **B,** Inspection of an acute anal fissure with a cotton-tipped swab. Once an acute fissure is identified, no internal examination is needed until the fissure is healed. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

FIG. E2 Chronic fissures are characterized by fibrosis, a skin tag at the distal extent of the fissure, and/or a hypertrophied papilla at the proximal end. The internal sphincter muscle may be visible at the base of the fissure. (From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.)

- Local anesthetic jelly (may exacerbate pruritus ani)
- Nitroglycerin ointment (0.4%): Apply 1 inch of ointment (equivalent to 1.5 mg of nitroglycerin) intraanally every 12 hours for up to 3 weeks. This medication (Rectiv) is expensive. Topical diltiazem (compounded by pharmacist) is also effective and much less expensive
- Suppositories *not* recommended
- Surgery, if failed medical management after 2 months
- An algorithm for the management of acute, chronic, and recurrent fissures is illustrated in Fig. E3

CHRONIC Rx

- Although less effective, medical treatment should be offered, as it is better tolerated and does not incur the risk of fecal incontinence.
- Surgery: Lateral internal anal sphincterotomy (Fig. E4, Fig. E5). It is a more durable treatment for chronic anal fissure compared with topical nitroglycerin therapy and does not compromise long-term fecal continence.
- Topical glyceryl trinitrate ointment.
- Injection of botulinum toxin (Fig. E6) (an injection into each side of the internal anal sphincter) is effective in healing chronic anal fissures in more than 90% of patients.
- Table E1 summarizes treatment of anal fissures.

DISPOSITION

Outpatient surgery

REFERRAL

- If fissure does not resolve with conservative therapy in 4 to 6 wk
- If patient prefers surgery for acute fissure
- If patient has chronic fissure

PEARLS & CONSIDERATIONS

COMMENTS

HIV-positive patients should be referred to clinicians who are well versed in the myriad infectious and neoplastic conditions that masquerade as anal ulcers in these patients.

In Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

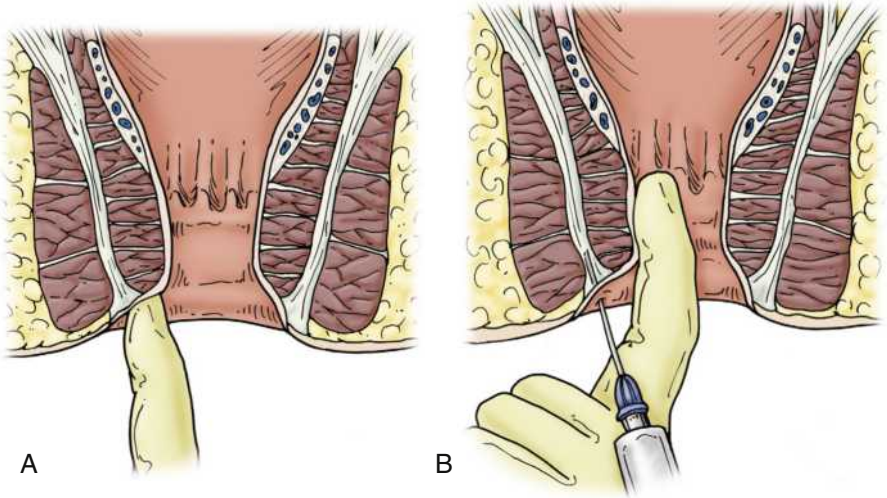

FIG. E6 Botox injection is performed by injection of Botox at 10 and 2 o'clock anteriorly in the intersphincteric groove. First, the index finger palpates the intersphincteric groove **(A),** and the needle is then placed within the groove **(B)** to inject the Botox. (Reprinted with permission from Braasch C, Sedgwick K, Veidenheimer M, Ellis H [eds]: *Atlas of abdominal surgery*, Philadelphia, 1991, Saunders; p. 199. In Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

TABLE E1 Treatment of Acute and Chronic Anal Fissures

Treatment	Comments
Acute	
Increase oral fluids, high-fiber diet, fiber supplements, Sitz baths, and stool softeners if needed	Avoid digital rectal examination until the fissure is healed unless the diagnosis is in doubt (then perform the examination in the operating room)
	Usually responds to these measures
Chronic	
As for acute, usually with the addition of one of the following:	Avoid digital examination unless the diagnosis is in doubt
0.2%-0.4% nitroglycerin ointment applied to the anal area	Headache is a common side effect
	Long-term success has been questioned
Calcium channel blockers (topical nifedipine or topical 2% diltiazem cream) applied to the anal area	Seem promising, but long-term success has been questioned
	Side effects (especially headache) may be less common than with nitroglycerin ointment
Botulinum toxin A injected into the anal muscle	Dose and optimal injection site are not clear
	Expensive
	Long-term success is unknown
Lateral internal sphincterotomy	Standard treatment
	Best results, with >90% long-term healing rate
	Durable
	Can lead to fecal incontinence

From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

Anaphylaxis

BASIC INFORMATION

DEFINITION

Anaphylaxis is a severe allergic reaction that is rapid in onset and life-threatening. It is characterized by respiratory, cardiovascular, gastrointestinal, and cutaneous manifestations, as well as vasodilatory hemodynamic changes in response to a particular allergen. Anaphylactoid reaction is an entity closely related to anaphylaxis and is caused by release of mast cells and basophil mediators triggered by non–immunoglobulin E (IgE)-mediated events.

SYNONYM

Anaphylactoid reaction

ICD-10CM CODES	
T78.2	Anaphylactic shock, unspecified, initial encounter
T78.00XA	Anaphylactic reaction due to unspecified food, initial encounter
T80.52XA	Anaphylactic reaction due to vaccination, initial encounter
T63.94XA	Toxic effect of contact with unspecified venomous animal, undetermined, initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The incidence of anaphylaxis in the U.S. is 50 to 2000 episodes per 100,000 persons. Lifetime prevalence is 0.05% to 2%, with a mortality rate of 1%. Anaphylaxis rates are 0.0004% for food, 0.7% to 10% for penicillin, 0.22% to 1% for contrast media, and 0.5% to 5% after insect stings. Annual mortality is nearly 2000 persons/yr in the U.S.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Urticaria, pruritus, skin flushing, angioedema (Table E1)
- Dyspnea, cough, wheezing, shortness of breath
- Nausea, vomiting, diarrhea, difficulty swallowing
- Hypotension, tachycardia, weakness, dizziness, malaise, vascular collapse (Table E2)

ETIOLOGY

Anaphylaxis results from a sudden systematic release of histamine and other inflammatory mediators from basophils and mast cells. This causes swelling of the mucous membranes and the urticarial rash on the skin. Virtually any substance may induce anaphylaxis. In an acute setting, the cause of anaphylaxis is often unidentifiable.

- Foods and food additives: Peanuts, tree nuts, eggs, shellfish, fish, cow's milk, fruits, soy
- Medications: Antibiotics (especially penicillins and sulfa-based agents), insulin, allergen extracts, opiates, vaccines, NSAIDs, contrast media, streptokinase
- Environmental exposures: Bee or wasp sting, snake venom, fire ant venom
- Blood products: Plasma, immunoglobulin, cryoprecipitate, whole blood
- Latex
- Box 1 summarizes agents frequently associated with immune and nonimmune types of anaphylaxis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Endocrine disorders (carcinoid, pheochromocytoma)
- Globus hystericus, anxiety disorder
- Systemic mastocytosis
- Pulmonary embolism, serum sickness, vasovagal reactions
- Severe asthma (the key clinical difference is the abrupt onset of symptoms in anaphylaxis versus a history of progressive worsening of symptoms)
- Scombroid poisoning
- Localized angioedema
- Septic shock or other form of vasodilatory shock
- Airway foreign body

WORKUP

Workup is aimed at ruling out other conditions that may mimic anaphylaxis. Given the potentially life-threatening nature of anaphylaxis, treatment should not be delayed. Clinical criteria for diagnosing anaphylaxis are summarized in Box 2.

LABORATORY TESTS

- Laboratory evaluation is generally not helpful because anaphylaxis is typically a clinical diagnosis.
- Elevated serum and urine histamine levels and serum tryptase levels can be useful for diagnosis of anaphylaxis, but these tests are not commonly available in the emergency setting.

IMAGING STUDIES

- Generally not helpful.
- Chest radiography for evaluation of foreign body aspiration or pulmonary pathology is indicated in patients with acute respiratory compromise.
- Consider ECG in all patients with sudden loss of consciousness or reports of chest pain or dyspnea and in any elderly patient. ECG in anaphylaxis usually reveals sinus tachycardia.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Establish and protect airway. Provide supplemental O_2 if indicated.
- Intravenous (IV) access should be rapidly established, and IV fluids (i.e., normal saline) should be administered.
- Cardiac monitoring is recommended.

ACUTE GENERAL Rx

- 0.3 to 0.5 mg intramuscular epinephrine (1:1000 concentration) should be rapidly administered for adults and children >30 kg in the lateral thigh. 0.01 mg/kg intramuscular epinephrine (1:1000 concentration) should be administered for children <30 kg. Intramuscular administration is preferred because it provides more reliable and quicker rise to effective plasma levels. The dose may be repeated after approximately 5 to 15 min if symptoms persist.
- Adjunct therapies include H_1 and H_2 receptor antagonists such as diphenhydramine 25 to 50 mg IV or IM (or PO in mild cases) and famotidine 20 to 40 mg IV (or PO in mild cases). Although useful to improve cutaneous erythema and pruritus, H_1 antagonists are not as effective as epinephrine, since onset of action is 1 to 2 hours and they are not effective in reversing upper airway obstruction or improving hypotension.
- Corticosteroids are not useful in the acute episode because of their slow onset of action; however, they should be administered in most cases to prevent prolonged or recurrent anaphylaxis. Commonly used agents are prednisone, methylprednisolone 40 to 250 mg IV in adults (1 to 2 mg/kg in children), or dexamethasone.
- Aerosolized β-agonists (e.g., albuterol, 2.5 to 5.0 mg, repeat prn 20 min) are useful to control bronchospasm.
- Vasopressor therapy with IV epinephrine (1:10,000 concentration) indicated in patients with refractory hypotension/cardiovascular collapse after crystalloid resuscitation.
- Patients taking beta-blocking medications may be refractory to initial treatment; consider administration of IV glucagon.
- Table 3 summarizes drugs and other agents used in anaphylaxis therapy.
- Fig. E1 illustrates an algorithm for the management of a patient with severe anaphylaxis.

PEARLS & CONSIDERATIONS

COMMENTS

- Patient education regarding the nature of the illness and preventive measures is recommended. A documented history of previous anaphylactic episodes or known triggers is the most reliable method of identifying individuals at risk.
- Prescription for a prefilled epinephrine syringe (EpiPen or EpiPen Jr.) should be given, and the patient should be instructed on the use of this emergency kit, and to carry it with them at all times. School-aged children should keep an additional EpiPen at school with the appropriate staff.

BOX 1 Agents Frequently Associated with Immune and Nonimmune Types of Anaphylaxis

Immunologic Mechanisms
IgE-mediated:
- Food (nuts, shellfish, fruits, etc.)
- Venoms (stinging insects)
- Medications (β-lactam antibiotics, NSAIDs, neuromuscular blocking agents, etc.)
- Natural rubber latex
- Seminal fluid
- Radiocontrast media (in some cases)

IgE-Independent
- Radiocontrast media (in most cases)
- Dextrans
- Monoclonal antibodies (Rituximab)
- Medications (β-lactam antibiotics, NSAIDs, etc.)
- Natural rubber latex
- Seminal fluid

Nonimmunologic Mechanisms
- Medications (opioids, protamine, etc.)

NSAIDs, Nonsteroidal antiinflammatory drugs.
From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

BOX 2 Clinical Criteria for Diagnosing Anaphylaxis

Anaphylaxis is highly likely when any one of the following three criteria is fulfilled:
1. Acute onset of an illness (minutes to several hours) with involvement of the skin, mucosal tissue, or both (e.g., generalized urticaria, itching or flushing, swollen lips/tongue/uvula) and at least one of the following:
   a. Respiratory compromise (e.g., dyspnea, wheeze/bronchospasm, stridor, reduced PEF, hypoxemia)
   b. Reduced blood pressure or associated symptoms of end-organ dysfunction (e.g., hypotonia collapse, syncope, incontinence)
   OR
2. Two or more of the following that occur rapidly after exposure to a likely allergen for that patient (minutes to several hours):
   a. Involvement of the skin-mucosal tissue (e.g., generalized urticaria, itch/flush, swollen lips/tongue/uvula)
   b. Respiratory compromise (e.g., dyspnea, wheeze/bronchospasm, stridor, reduced PEF, hypoxemia)
   c. Reduced blood pressure or associated symptoms (e.g., hypotonia collapse, syncope, incontinence)
   d. Persistent gastrointestinal symptoms (e.g., crampy abdominal pain, vomiting)
   OR
3. Reduced blood pressure after exposure to known allergen for that patient (minutes to several hours)
   a. Infants and children: low systolic blood pressure (age-specific) or >30% decrease in systolic blood pressure
   b. Adults: systolic blood pressure of <90 mm Hg or >30% decrease from that person's baseline

PEF, Peak expiratory flow.
From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

TABLE 3 Management of a Patient with Anaphylaxis

Treatment	Mechanism(s) of Effect	Dosage(s)	Comments; Adverse Reactions
PATIENT EMERGENCY MANAGEMENT (DEPENDENT ON SEVERITY OF SYMPTOMS)			
Epinephrine (adrenaline)	α_1-, β_1-, β_2-Adrenergic effects	0.01 mg/kg, up to 0.5 mg IM in lateral thigh Adrenaclick, Auvi-Q, EpiPen Jr./EpiPen: 0.15 mg IM for 8-25 kg 0.3 mg IM for 25 kg or more Epinephrine autoinjector: 0.1 mg for 7.5-15 kg 0.15 mg for 15 to 25 kg 0.3 mg for 25 kg or more	Tachycardia, hypertension, nervousness, headache, nausea, irritability, tremor
Cetirizine (liquid)	Antihistamine (competitive of H_1 receptor)	Cetirizine liquid: 5 mg/5 ml 0.25 mg/kg, up to 10 mg PO	Hypotension, tachycardia, somnolence
Alternative: Diphenhydramine	Antihistamine (competitive of H_1 receptor)	1.25 mg/kg up to 50 mg PO or IM	Hypotension, tachycardia, somnolence, paradoxic excitement
Transport to an emergency facility			
EMERGENCY PERSONNEL MANAGEMENT (DEPENDENT ON SEVERITY OF SYMPTOMS)			
Epinephrine (adrenaline)	α_1-, β_1-, β_2-Adrenergic effects	0.01 mg/kg, up to 0.5 mg IM in lateral thigh Epinephrine autoinjector: 0.1 mg for 7.5-15 kg 0.15 mg for 15 to 25 kg 0.3 mg for 25 kg or more 0.01 ml/kg/dose of 1:1,000 (vial) solution, up to 0.5 ml IM May repeat every 10-15 min For severe hypotension: 0.01 ml/kg/dose of 1:10,000 slow IV push	Tachycardia, hypertension, nervousness, headache, nausea, irritability, tremor

TABLE 3 Management of a Patient with Anaphylaxis—cont'd

Treatment	Mechanism(s) of Effect	Dosage(s)	Comments; Adverse Reactions
SUPPLEMENTAL OXYGEN AND AIRWAY MANAGEMENT			
Volume Expanders			
Crystalloids (normal saline or Ringer lactate)		30 ml/kg in 1st hr	Rate titrated against BP response If tolerated, place patient supine with legs raised.
Colloids (hydroxyethyl starch)		10 ml/kg rapidly followed by slow infusion	Rate titrated against BP response If tolerated, place patient supine with legs raised.
Antihistamines			
Cetirizine (liquid)	Antihistamine (competitive of H_1 receptor)	Cetirizine liquid: 5 mg/5 ml 0.25 mg/kg, up to 10 mg PO	Hypotension, tachycardia, somnolence
Alternative: Diphenhydramine	Antihistamine (competitive of H_1 receptor)	1.25 mg/kg, up to 50 mg PO, IM, or IV	Hypotension, tachycardia, somnolence, paradoxic excitement
Ranitidine	Antihistamine (competitive of H_2 receptor)	1 mg/kg, up to 50 mg IV Should be administered slowly	Headache, mental confusion
Alternative: Cimetidine	Antihistamine (competitive of H_2 receptor)	4 mg/kg, up to 200 mg IV Should be administered slowly	Headache, mental confusion
Corticosteroids			
Methylprednisolone	Antiinflammatory	Solu-Medrol (IV): 1-2 mg/kg, up to 125 mg IV Depo-Medrol (IM): 1 mg/kg, up to 80 mg IM	Hypertension, edema, nervousness, agitation
Prednisone	Antiinflammatory	1 mg/kg up, to 75 mg PO	Hypertension, edema, nervousness, agitation
Nebulized albuterol	β-Agonist	0.83 mg/ml (3 ml) via mask with O_2	Palpitations, nervousness, CNS stimulation, tachycardia; use to supplement epinephrine when bronchospasm appears unresponsive; may repeat
POSTEMERGENCY MANAGEMENT			
Antihistamine	Cetirizine (5-10 mg qd) or loratadine (5-10 mg qd) for 3 days		
Corticosteroids	*Optional:* Oral prednisone (1 mg/kg up to 75 mg) daily for 3 days		
Preventive Treatment			
Prescription for epinephrine autoinjector and antihistamine Provide written plan outlining patient emergency management (may download form from http://www.aap.org or http://www.foodallergy.org) Follow-up evaluation to determine/confirm etiology Immunotherapy for insect sting allergy			
Patient Education			
Instruction on avoidance of causative agent Information on recognizing early signs of anaphylaxis Stress early treatment of allergic symptoms to avoid systemic anaphylaxis Encourage wearing medical identification jewelry			

BP, Blood pressure; *CNS,* central nervous system; *IM,* intramuscularly; *IV,* intravenously; *PO,* orally; *qd,* every day.
From Kliegman, RM: *Nelson textbook of pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

- Patients should also be advised to carry or wear a MedicAlert ID describing substances that have caused anaphylaxis.
- Avoidance of radiologic contrast is also recommended in those who have had a prior reaction. However, pretreatment regimens with methylprednisolone or diphenhydramine, exist for those who have had contrast reactions in the past.
- Venom immunotherapy immediately after a sting is effective and recommended for up to 5 yr after the anaphylactic incident.

BASIC INFORMATION

DEFINITION

Aplastic anemia (AA) refers to a bone marrow failure syndrome characterized by immune-mediated bone marrow destruction and peripheral blood pancytopenia. Severe aplastic anemia (SAA) is defined by the presence of two of the following criteria: Neutrophil counts $<50 \times 10^9$/L, platelet counts $<20 \times 10^9$/L, or corrected reticulocyte count <1%.

SYNONYMS

Aplastic anemia
AA
Refractory anemia
Hypoplastic anemia

ICD-10CM CODES

D61.9	Aplastic anemia, unspecified
D60.9	Acquired pure red cell aplasia, unspecified
D60.8	Other acquired pure red cell aplasias
D61.09	Other constitutional aplastic anemia
D61.1	Drug-induced aplastic anemia
D61.2	Aplastic anemia due to other external agents
D61.3	Idiopathic aplastic anemia
D61.89	Other specified aplastic anemias and other bone marrow failure syndromes

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The annual incidence of aplastic anemia is 2 cases per million in the Western population and 2 to 3 times higher in Asia.
PREDOMINANT SEX AND AGE: The incidence has two peaks, with most patients presenting between ages 15 and 30 yr or after 60 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Fatigue, pallor, exertional shortness of breath, or palpitations are seen secondary to anemia.
- Mucosal bleeding, easy bruising (Fig. E1), petechiae or heavy menstrual bleeding is seen secondary to thrombocytopenia.
- Infection is uncommon at clinical presentation, but severe neutropenia may lead to fever and sore throat.
- Various physical manifestations like short stature, skeletal or nail changes may be seen in congenital forms of aplastic anemia.

ETIOLOGY

- In most patients with idiopathic aplastic anemia, bone marrow failure results from immunologically mediated, active destruction of hematopoietic cells by lymphocytes.
- Mutations in *TERT,* the gene for the RNA component of telomerase, cause short telomerases in congenital aplastic anemia and in some cases of apparently acquired hematopoietic failure. In patients with severe aplastic anemia receiving immunosuppressive therapy (IST), telomere length is unrelated to response but is associated with risk of relapse, clonal evolution, and overall survival.
- Table E1 summarizes a classification of aplastic anemia.
- Common etiologic factors in acquired aplastic anemia include:
  1. Toxins (e.g., benzene, insecticides)
  2. Drugs (e.g., felbamate, cimetidine, NSAIDs, antiepileptics, gold salts, chloramphenicol, sulfonamides, trimethadione, quinacrine, phenylbutazone). Table E2 describes a classification of drugs and chemicals associated with aplastic anemia
  3. Ionizing radiation
  4. Infections (e.g., hepatitis C, HIV, Epstein-Barr virus, parvovirus B19)
- Inherited aplastic anemia:
  1. Fanconi anemia
  2. Reticular dysgenesis
  3. Dyskeratosis congenita
  4. Nonhematologic syndromes (Down syndrome, etc.)
  5. Shwachman-Diamond syndrome
- Pregnancy.
- Idiopathic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bone marrow infiltration from lymphoma, carcinoma, myelofibrosis
- Severe infection
- Hypoplastic myelodysplastic syndrome
- Hypersplenism
- Hairy cell leukemia

WORKUP

- Diagnostic workup (Fig. E2) consists primarily of bone marrow aspiration and biopsy, and laboratory evaluation (CBC and examination of peripheral blood smear).
- Bone marrow examination generally shows paucity or absence of hematopoietic precursor cells (Fig. E3, *B* and *C,* and Fig. E4); patients with pure red cell aplasia demonstrate only absence of red blood cell (RBC) precursors in the marrow.

LABORATORY TESTS

- CBC reveals pancytopenia (Fig. E3, *A*). Macrocytosis and toxic granulation of neutrophils may also be present. Isolated cytopenias may occur in the early stages.
- Reticulocytopenia can be seen.
- Additional laboratory evaluation should include Ham test and/or peripheral blood flow cytometry to exclude paroxysmal nocturnal hemoglobinuria (PNH) and testing for hepatitis C.

IMAGING STUDIES

MRI with spin-echo sequence is helpful in the study of bone marrow disease, and the high fat content of an aplastic marrow can be easily seen on MRI.

TREATMENT

NONPHARMACOLOGIC THERAPY

Discontinue any potential offending drugs or agents.

FIG. E1 Clinical presentation of aplastic anemia. A, Ecchymosis in women with pancytopenia. **B,** Submucosal hematomas. **C,** Petechial eruptions in a patient with thrombocytopenia. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

TABLE E1 A Classification of Aplastic Anemia

Acquired Aplastic Anemia

- Secondary aplastic anemia
- Irradiation
- Drugs and chemicals
- Regular effects
- Cytotoxic agents
- Benzene
- Idiosyncratic reactions
- Chloramphenicol
- Nonsteroidal antiinflammatory drugs
- Antiepileptics
- Gold
- Other drugs and chemicals
- Viruses
- Epstein-Barr virus (infectious mononucleosis)
- Hepatitis virus (non-A, non-B, non-C, non-G hepatitis)
- Parvovirus (transient aplastic crisis, some pure red cell aplasia)
- HIV (acquired immunodeficiency syndrome [AIDS])
- Immune diseases
- Eosinophilic fasciitis
- Hyperimmunoglobulinemia
- Thymoma and thymic carcinoma
- Graft-versus-host disease in immunodeficiency
- Paroxysmal nocturnal hemoglobinuria
- Pregnancy
- Idiopathic aplastic anemia

Inherited Aplastic Anemia

- Fanconi anemia
- Dyskeratosis congenita
- Shwachman-Diamond syndrome
- Reticular dysgenesis
- Amegakaryocytic thrombocytopenia
- Familial aplastic anemias
- Preleukemia (e.g., monosomy 7)
- Nonhematologic syndromes (e.g., Down, Dubowitz, Seckel)

From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE E2 Classification of Drugs and Chemicals Associated with Aplastic Anemia

Agents That Regularly Produce Bone Marrow Depression as a Major Toxic Effect When Used in Commonly Used Doses or Normal Exposures

- Cytotoxic drugs used in cancer chemotherapy
- Alkylating agents (busulfan, melphalan, cyclophosphamide)
- Antimetabolites (antifolic compounds, nucleotide analogues), antimitotics (vincristine, vinblastine, colchicine)
- Some antibiotics (daunorubicin, doxorubicin [Adriamycin])
- Benzene (and less often benzene-containing chemicals: Kerosene, carbon tetrachloride, Stoddard solvent, chlorophenols)

Agents Probably Associated with Aplastic Anemia but with a Relatively Low Probability Relative to Their Use

- Chloramphenicol
- Insecticides
- Antiprotozoals (quinacrine and chloroquine)
- Nonsteroidal antiinflammatory drugs (including phenylbutazone, indomethacin, ibuprofen, sulindac, diclofenac, naproxen, piroxicam, fenoprofen, fenbufen, aspirin)
- Anticonvulsants (hydantoins, carbamazepine, phenacemide, ethosuximide)
- Gold, arsenic, and other heavy metals, such as bismuth and mercury
- Sulfonamides as a class
- Antithyroid medications (methimazole, methylthiouracil, propylthiouracil)
- Antidiabetes drugs (tolbutamide, carbutamide, chlorpropamide)
- Carbonic anhydrase inhibitors (acetazolamide, methazolamide, mesalazine)
- D-Penicillamine
- 2-Chlorodeoxyadenosine

Agents More Rarely Associated with Aplastic Anemia

- Antibiotics (streptomycin, tetracycline, methicillin, ampicillin, mebendazole and albendazole, sulfonamides, flucytosine, mefloquine, dapsone)
- Antihistamines (cimetidine, ranitidine, chlorpheniramine)
- Sedatives and tranquilizers (chlorpromazine, prochlorperazine, piperacetazine, chlordiazepoxide, meprobamate, methyprylon, remoxipride)
- Antiarrhythmics (tocainide, amiodarone)
- Allopurinol (can potentiate marrow suppression by cytotoxic drugs)
- Ticlopidine
- Methyldopa
- Quinidine
- Lithium
- Guanidine
- Canthaxanthin
- Thiocyanate
- Carbimazole
- Cyanamide
- Deferoxamine
- Amphetamines

From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, WB Saunders.

ACUTE GENERAL Rx

- Aggressive treatment of neutropenic fevers with empiric broad-spectrum antibiotics.
- Administer platelet and packed RBC transfusions as needed; however, it is important to avoid frequent transfusions in patients who are candidates for stem cell transplantation (SCT) so as to reduce the incidence of alloimmunization.
- Fig. E5 describes a treatment algorithm for aplastic anemia.

CHRONIC Rx

- Initial treatment can include observation and supportive care alone. Progression to transfusion dependence or to criteria meeting definition of SAA necessitates definitive treatment. Upfront HLA-typing of the patient is also required upon confirmation of a diagnosis of SAA.
- The major treatment options for SAA are IST and allogeneic SCT. Treatment decisions are based on age, availability of histocompatible stem cell donor, and presence of comorbidities. Patients <40 yr are treated with upfront allogeneic SCT

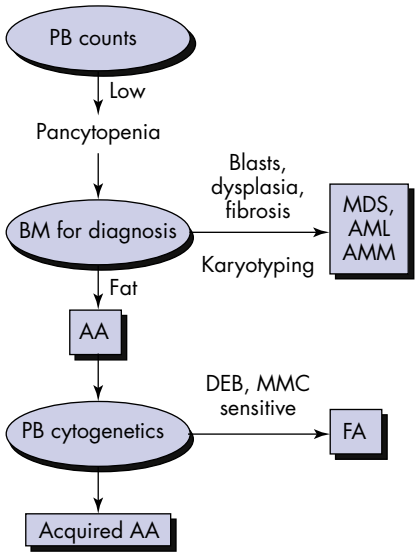

FIG. E2 Diagnostic algorithm in aplastic anemia *(AA).* *AML,* Acute myeloid leukemia; *AMM,* agnogenic myeloid metaplasia; *BM,* bone marrow; *DEB,* diepoxybutane; *FA,* Fanconi anemia; *MDS,* myelodysplastic syndrome; *MMC,* mitomycin C; *PB,* peripheral blood. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

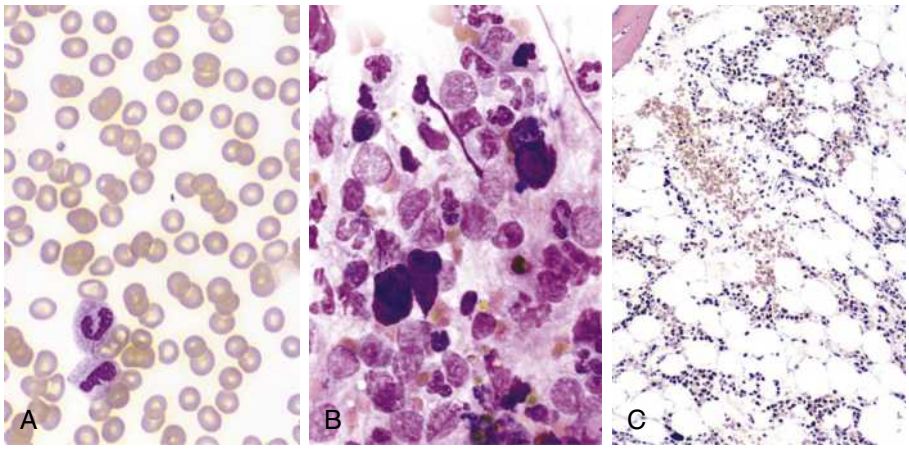

FIG. E3 Pancytopenia in measles-associated aplastic anemia. A, Note the toxic granulation in the neutrophils. The hypocellular bone marrow smear contains numerous mast cells **(B),** and the trephine biopsy reflects subtotal aplasia **(C).** (From Jaffe ES et al: *Hematopathology,* Philadelphia, 2011, WB Saunders.)

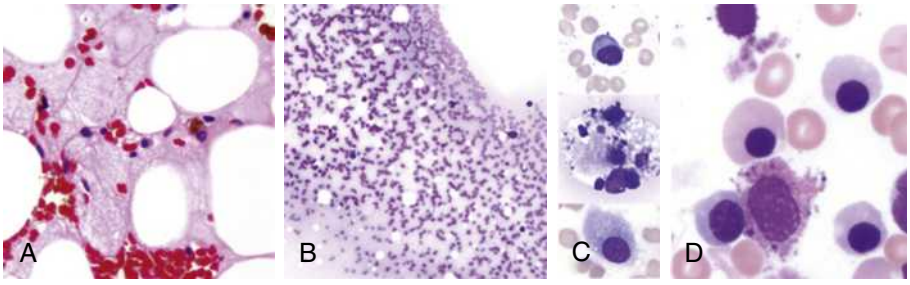

FIG. E4 Some morphologic features occasionally observed in patients with aplastic anemia. Empty marrow with eosinophilic ground substance consistent with serous atrophy or stromal injury **(A),** possibly indicative of marrow damage. Scanty marrow aspirate in severe disease **(B)** showing only rare nucleated elements, many of which are from blood. Presence of plasma cells, histiocytes, and osteoblasts **(C)** confirms marrow nature of aspirate. note: Sometimes the histiocytes can show hemophagocytosis. Megaloblastoid erythropoiesis **(D)** is sometimes seen in aplastic anemia and in recovery. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 6, Philadelphia, 2013, Elsevier.)

whereas patients >40 yrs old have traditionally been treated with IST initially. Patients who are >40 yrs old can be recommended for SCT if there is suboptimal response to IST after 4 mo of therapy.

- Allogeneic SCT from a human leukocyte antigen (HLA)-matched sibling donor is potentially curative. Patients who do not have a matched sibling can be treated with a matched unrelated donor (MUD) SCT. Finally, there is increasing efficacy data with the use of haploidentical donor SCT when related donors are unavailable.
- IST typically consists of the regimen of cyclosporine with or without antithymocyte globulin (ATG) in patients <60 yr; in older patients, ATG is administered only in fit patients with low comorbidities.
- The use of hematopoietic growth factors such as granulocytic colony-stimulating factor (G-CSF) is not associated with improvement in survival outcomes in this setting.
- Studies have shown an association between leukocyte telomere length and outcomes in MUD-SCT. Longer donor leukocyte telomere length was associated with increased 5-yr survival.
- Patients who fail to respond to initial IST are candidates for alternative donor SCT or other immunosuppressive therapy such as Alemtuzumab (anti-CD52 monoclonal antibody).
- Other immunosuppressive agents such as cyclophosphamide or corticosteroids also have a supportive role in the treatment of SAA.
- Androgens such as danazol are effective second-line agents.
- The oral thrombopoietin mimetic eltrombopag is used for platelet recovery in refractory SAA. Recent data have demonstrated encouraging outcomes when used in combination with IST in the treatment of newly diagnosed patients.

DISPOSITION

- A recent retrospective analysis revealed 10-yr survival rates of 86%, 76%, and 55% with allogeneic SCT performed between 2000 and 2010 in patients <20 yr, 21 to 40 yrs old, and >40 yrs old, respectively.
- Recent data with the use of allogeneic SCT in patients >50 yr have demonstrated improved survival outcomes especially in patients with higher performance scores and matched sibling donors, but patients >65 yr are likely to have higher rates of severe graft versus host disease.
- Approximately 50% of patients treated with IST alone achieve long-term remissions and do not have disease relapse.
- Graft rejection and graft-versus-host disease are the major complications of allogeneic SCT.
- Approximately 10% to 15% of patients develop clonal evolution, which manifests as myelodysplastic syndrome or acute myeloid leukemia.
- The improved outcomes with allogeneic SCT have prompted recommendations for its earlier use in the majority of patients.

REFERRAL

Hematology referral is indicated in all patients with aplastic anemia.

BASIC INFORMATION

DEFINITION

Autoimmune hemolytic anemia (AIHA) is anemia secondary to premature clearance of red blood cells (RBCs) caused by binding of autoantibodies and/or complement to RBCs. Primary AIHA comprises approximately 50% of cases, whereas secondary AIHA is usually associated with diseases or drugs. The classification of the hemolytic anemias is described in Table 1.

SYNONYMS

Autoimmune hemolytic anemia
Cold agglutinin disease
Drug-induced hemolytic anemia
Warm autoimmune hemolytic anemia

ICD-10CM CODES

D59.0	Drug-induced autoimmune hemolytic anemia
D59.1	Other autoimmune hemolytic anemias

EPIDEMIOLOGY & DEMOGRAPHICS

The annual incidence is 1 to 3 cases per 100,000 persons, with 10% mortality; most common in women <50 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most common presentation is dyspnea and fatigue.
- Pallor, jaundice may be present.
- Tachycardia with a flow murmur may be present if anemia is pronounced.
- Patients with intravascular hemolysis may present with dark urine and back pain.
- The presence of hepatomegaly and/or lymphadenopathy suggests an underlying lymphoproliferative disorder or malignancy; splenomegaly may indicate hypersplenism as a cause of hemolysis.
- Chronic process with multiple relapses typically seen during the course of the disease.

TABLE 1 Classification of the Hemolytic Anemias

Acquired

Environmental factors
- Antibody: Immunohemolytic anemias
- Mechanical trauma: TTP, HUS, heart valve
- Toxins, infectious agents: Malaria, etc.

Membrane defects
- Paroxysmal nocturnal hemoglobinuria
- Spur cell anemia
- Hereditary spherocytosis, etc.

Congenital

Defects of cell interior
- Hemoglobinopathies: Sickle cell, thalassemia
- Enzymopathies: G6PD deficiency, etc.

G6PD, Glucose-6-phosphate dehydrogenase; *HUS,* hemolytic-uremic syndrome; *TTP,* thrombotic thrombocytopenic purpura.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, WB Saunders.

ETIOLOGY

- Warm antibody mediated: IgG only (often idiopathic or associated with leukemia, lymphoma [Table 2], thymoma, myeloma, viral infections [Table 3], babesiosis, and collagen-vascular disease)
- Cold antibody mediated: IgM and complement in majority of cases (often idiopathic; at times associated with infections, lymphoma, or cold agglutinin disease)
- Il-33 may have a role in promoting increasing RBC autoantibodies in AIHA
- Drug induced (Table 4): Three major mechanisms:
  1. Antibody directed against Rh complex (e.g., methyldopa)
  2. Antibody directed against RBC-drug complex (hapten induced; e.g., penicillin)
  3. Antibody directed against complex formed by drug and plasma proteins; the drug-plasma protein-antibody complex causes destruction of RBCs (innocent bystander; e.g., quinidine)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hemolytic anemia caused by membrane defects (acquired: paroxysmal nocturnal hemoglobinuria, spur cell anemia, Wilson disease; inherited: spherocytosis, elliptosis), hemoglobinopathies, and enzyme deficiencies (G6PD, pyruvate kinase)
- Non–immune mediated (microangiopathic hemolytic anemias, hypersplenism, cardiac valve prosthesis, giant cavernous hemangiomas, march hemoglobinuria, physical agents, infections, heavy metals, certain drugs [nitrofurantoin, sulfonamides, ribavirin])
- Chronic lymphocytic leukemia (CLL) can be a cause of direct antiglobulin test (DAT) positivity (15% of CLL cases) without AIHA. In a series of patients treated with fludarabine and cyclophosphamide, only 30% of patients with DAT+ disease developed AIHA after therapy; conversely, 85% of patients with AIHA were previously positive for DAT

TABLE 2 Secondary Autoimmune Hemolytic Anemia in Malignancies

Malignancy	Prevalence	WAIHAs	CAIHAs
MGUS	Very low	None	All
All NHL	0.23%-2.6%		
CLL	4.3%-9%	90%	10%
SMZL	10%	2/3	1/3
LPL	3%-5%	None	Most
Angioimmunoblastic T-cell lymphoma	13%	One third	Two thirds
Hodgkin lymphoma	0.19%-1.7%	All	None
Ovarian teratoma	Very low	All	None
Solid tumors	Very low	Two thirds	One third

CAIHAs, Cold antibody autoimmune hemolytic anemias; *CLL,* chronic lymphocytic leukemia; *LPL,* lymphoplasmacytic lymphoma; *MGUS,* monoclonal gammopathy with unknown significance; *NHL,* non-Hodgkin lymphoma; *SMZL,* splenic marginal zone lymphoma; *WAIHAs,* warm antibody autoimmune hemolytic anemias.

TABLE 4 Drug-Induced Autoimmune Hemolytic Anemia

Drug	Risk Factors	AIHA Onset	Type of AIHA	Response to Treatment	Diseases Treated
Methyldopa	Not known	Delayed	WAIHA	Resolution after withdrawal	Hypertension
IFN-α	Pretherapeutic positive DAT	Delayed (8-11 mo)	WAIHA	Resolution spontaneous or after steroids	Hepatitis C; hematologic malignancies
Efazulimab	Not known	Many mo	WAIHA	Resolution after withdrawal	Arthritis (rare)
Etanercept	Not known	Delayed	CAIHA	Resolution after rituximab	Rheumatoid arthritis (rare)
Fludarabine Cladribine Pentostatin	CLL Pretherapeutic positive DAT result	Early (median, 3-4 cycle) or delayed	WAIHA Mixed AIHA	Half of AIHA resolve after steroids	CLL Lymphomas[a] AML[a]
Bendamustin	CLL	No or only very low risk of AIHA			CLL Lymphomas
Chlorambucil	CLL	Delayed onset	WAIHA		CLL
Eculizumab	Patients with incomplete response	After treatment	CAIHA		PNH
Lenalidomide		During treatment	WAIHA	Resolution after withdrawal	One case treated for lymphoma
Checkpoint inhibitors (anti-CTLA4, anti-PD1/PD1L)		During treatment	WAIHA		Solid tumors, Hodgkin lymphoma

AIHA, Autoimmune hemolytic anemia; *AML,* acute myeloid leukemia; *CAIHA,* cold autoimmune hemolytic anemia; *CLL,* chronic lymphocytic leukemia; *DAT,* direct antiglobulin test; *IFN,* interferon; *PNH,* paroxysmal nocturnal hemoglobinuria; *WAIHA,* warm autoimmune hemolytic anemia.
[a]No or very low risk.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE 5 Positive Direct Antiglobulin Test Findings, Characteristic Features of Autoantibody in Autoimmune Hemolytic Anemia

	Warm AIHA	CHAD	Mixed-AIHA	PCH	IgA AIHA
DAT	IgG or IgG + C3 or IgG + C3 + IgM	C3 or C3 + IgM	IgG + C3 + IgM	C3	Neg with polyspecific reagent Pos with anti-IgA
Antibody characteristic					
1) Antibody subclass	IgG	IgM	IgG + IgM	IgG	IgA
1) Specificity	Apparent Rh specificity (common)	I, i, Pr		P	
1) Thermal reactivity (in vitro)	Optimal at 37°C (98.6° F) by IAT	0-30° C (32-86° F) by saline agglutination	Combined	0-24° C (32-75.2° F), biphasic in nature	
1) Antibody titer at 4° C (39.2° F)	Not applicable	≥256	Usually <64 but can be >256	Usually <32	
Autoagglutination	No	Common	Common	Less common	No

AIHA, Autoimmune hemolytic anemia; *C,* complement; *CHAD,* cold hemagglutinin disease; *DAT,* direct antiglobulin test; *IAT,* indirect antiglobulin test; *Ig,* immunoglobulin; *Neg,* negative; *PCH,* Paroxysmal cold hemoglobinuria; *Pos,* positive.
The determination of autospecificity is not required for diagnosis of CHAD, but confirmation of high thermal amplitude (i.e., cold autoagglutinin reacting at or above 30° C [86° F]) is essential.
From Bain BJ et al: *Dacie and Lewis practical haematology,* ed 12, Philadelphia, 2017, Elsevier.

WORKUP

Evaluation consists primarily of laboratory evaluation to confirm hemolysis and exclude other causes of the anemia. Although most cases of AIHA are idiopathic, potential causes should always be sought.

LABORATORY TESTS

- The basic features of hemolytic anemia are reticulocytosis (if no concurrent bone marrow suppression), low haptoglobin levels, elevated indirect bilirubin, and elevated LDH.
- Initial laboratory tests: Complete blood count (anemia), reticulocyte count (elevated), liver function studies (elevated indirect bilirubin, LDH), evaluation of peripheral smear (Fig. E1).
- A direct antiglobulin test (DAT, Coombs test) is initially performed with a polyspecific antibody to detect IgG or complement C3d bound to RBCs. If the DAT is positive, the diagnosis of autoimmune hemolytic anemia (AIHA) is confirmed. A positive direct Coombs test indicates presence of antibodies or complement on the surface of RBCs; positive indirect Coombs test implies presence of anti-RBC antibodies freely circulating in the patient's serum. Positive DAT findings and characteristic features of autoantibody in AIHA are summarized in Table 5. Typical serologic features of the different types of drug-induced hemolytic anemia of immunologic origin are summarized in Table 6.
- If the DAT is positive with IgG alone or with IgG + C3d, the AIHA is most likely due to warm antibody (WAIHA), whereas if the DAT is positive with C3d only, it is most likely caused by a cold antibody (CAIHA).
- Hepatitis serology, antinuclear antibody.
- Urinary tests may reveal hemosiderinuria or hemoglobinuria (documenting intravascular hemolysis).

IMAGING STUDIES

- Chest x-ray.
- CT scans of chest, abdomen, and pelvis should be considered if underlying lymphoproliferative disorder is suspected.

TABLE 6 Serologic Features of the Different Types of Drug-Induced Hemolytic Anemia of Immunologic Origin

Mechanism	Prototype drug	DAT	IAT		
Drug-dependent antibody			No drug	Serum + drug	Eluate + drug
C′ activation	Quin(id)ine	C′*	Neg	C′*	Neg
No C′ activation	Penicillin	IgG	Neg	IgG	IgG
Autoantibody	α-Methyldopa	IgG	IgG	NA	NA

C′, Complement; *IgG,* immunoglobulin G; *NA,* not applicable; *Neg,* negative.
*Occasionally also IgG.
From Bain BJ et al: *Dacie and Lewis practical haematology,* ed 12, Philadelphia, 2017, Elsevier.

TABLE 7 Treatment Options for Primary and Secondary Warm Autoimmune Hemolytic Anemia and Cold Autoimmune Hemolytic Anemia

Disease or Condition	First Line	Second Line	Beyond Second Line	Last Resort
Primary AIHA	Steroids (trituximab)	Splenectomy Rituximab	Azathioprine, MMF, cyclosporine, cyclophosphamide	High-dose cyclophosphamide, alemtuzumab
B- and T-cell NHL	Steroids	Chemotherapy +/– rituximab (splenectomy in SMZL)	Other anti-CD23 antibodies/ ibrutinib	
Hodgkin lymphoma	Steroids	Chemotherapy		
Solid tumors	Steroids Surgery			
Ovarian dermoid cyst	Ovariectomy			
SLE	Steroids	Azathioprine	MMF	Rituximab Autologous SCT
Ulcerative colitis	Steroids	Azathioprine		Total colectomy
CVID	Steroids + IgG replacement			
ALPD	Steroids	MMF	Sirolimus	
Wiskott-Aldrich syndrome	Steroids	Allogeneic SCT		
Allogeneic SCT	Steroids	Rituximab*	Splenectomy T-cells infusion	
Organ transplantation	Reduction of immune suppression, steroids			
Drug induced	Withdrawal	Steroids		
Primary CAD	Protection from cold exposure	Rituximab Chlorambucil	Fludarabine + rituximab	Eculizumab,† bortezomib†
PCH	Supportive treatment (postinfectious)	Rituximab* (chronic)		

AIHA, Autoimmune hemolytic anemia; *ALPD,* autoimmune lymphoproliferative disorders; *CAD,* cold agglutinin disease; *CVID,* common variable immune deficiency; *IgG,* immunoglobulin G; *MMF,* mycophenolate mofetil; *NHL,* non-Hodgkin lymphoma; *PCH,* paroxysmal cold hemoglobinuria; *SCT,* stem cell transplantation; *SLE,* systemic lupus erythematosus; *SMZL,* splenic marginal zone lymphoma.
*Early second-line treatment because of known poor response to steroids.
†Off-label use in single cases.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, WB Saunders.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Discontinuation of any potentially offending drugs
- Plasmapheresis and exchange transfusion for severe life-threatening cases only
- Avoid cold exposure in patients with cold antibody

ACUTE GENERAL Rx

- Prednisone 1 to 2 mg/kg/day in divided doses is initially used in warm antibody AIHA. Corticosteroids are generally ineffective in cold antibody AIHA. In cold agglutinin disease treatment, modalities consist of cold avoidance, therapy of underlying lymphoproliferative disorder, and use of rituximab and plasmapheresis in severe cases.
- Two randomized controlled trials have demonstrated improved outcomes and duration of response with the combined upfront use of steroids and rituximab, and this is also a standard option in clinical use.
- For patients relapsing or refractory to initial steroid therapy, the use of rituximab has in most cases replaced the use of splenectomy. Splenectomy now is more often used in patients refractory to both corticosteroids and rituximab use previously.
- Immunosuppressive drugs and/or immunoglobulins are recommended after failure of the above approaches to produce an adequate remission.
- Danazol, typically used in conjunction with corticosteroids (may be useful in warm antibody AIHA).
- Immunosuppressive drugs (azathioprine, cyclophosphamide) may be useful in warm antibody AIHA but are indicated only after both corticosteroids and splenectomy (unless surgery is contraindicated) have failed to produce an adequate remission.
- Table 7 summarizes treatment options for primary and secondary warm autoimmune hemolytic anemia and cold autoimmune

TABLE 8 Second-Line Treatment Options after Steroids

Treatment	Dosing and Application	Side Effects	Precautions
Splenectomy (acute)	Preferentially laparoscopic	Infections, thrombosis	Postoperative thromboprophylaxis
Splenectomy (long term)	—	Infections Venous thrombosis	Vaccination, patient information
Rituximab	375 mg/m^2 on days 1, 8, 15, and 22 IV	Infusional reactions Infections	Premedication with antihistamines (and steroids)
Danazol	200-400/day PO	Hepatotoxicity	None
Cyclophosphamide	PO or IV Dose adjusted to neutrophil count	Neutropenia Mutagenesis	Neutrophil count monitoring, bladder protection after high doses
Azathioprine	2.0-3.mg/kg/day PO Dose adjusted to neutrophil count	Neutropenia	Neutrophil count monitoring; avoid interaction with other drugs (e.g., allopurinol)
MFF	1-2 × 1 g/day PO	Gastrointestinal	
Cyclosporine	PO Dose adjusted to blood levels of CyA Target level, 200-400 ng/ml	Nephrotoxicity Gum hyperplasia	Monitoring of CyA levels and creatinine
Alemtuzumab	SC (variable doses)	Neutropenia	Antiinfectious prophylaxis
Complement inhibition with eculizumab, TNT009		Infections	Vaccination

CyA, Cyclosporine A; *IV,* intravenous; *MMF,* mycophenolate mofetil; *PO,* oral; *SC,* subcutaneous.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

hemolytic anemia. Second-line treatment options after steroids are described in Table 8.

DISPOSITION

Prognosis is generally good unless anemia is associated with underlying disorder with a poor prognosis (e.g., leukemia, myeloma).

REFERRAL

- Hematology referral in all cases of AIHA
- Surgical referral for splenectomy in refractory cases

PEARLS & CONSIDERATIONS

COMMENTS

- The direct antiglobulin test demonstrates the presence of antibodies or complement on the surface of RBCs and is the hallmark of autoimmune hemolysis.
- Warm AIHA is often associated with autoimmune diseases, whereas cold AIHA often follows viral infections (e.g., mononucleosis) and *Mycoplasma pneumoniae* infections.
- HIV can induce both warm and cold AIHA.
- Hemolytic anemia is a common autoimmune complication of hematopoietic stem cell transplantation occurring in up to 6% of patients as a late complication (median 202 days); it presents as either warm or cold AIHA.

BASIC INFORMATION

DEFINITION

Inflammatory anemia, also known as *anemia of chronic disease (ACD),* is a disorder of iron homeostasis (Table 1) promoted by hepcidin-25 in response to an inflammatory condition.

SYNONYMS

Inflammatory anemia
Anemia of chronic disease
ACD

ICD-10CM CODES

D63.8	Anemia in chronic diseases classified elsewhere
D63.0	Anemia in neoplastic disease
D64.8	Anemia, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- Second-most prevalent anemia after iron deficiency anemia:
  1. Around 11% of men and 10% of women ages 65 to 85 yr
  2. >20% of adults older than 85 yr

Pathophysiology (Fig. 1)

Iron is carried in the bloodstream shelled by a hollow protein called transferrin (<0.2% of total iron body content) or at the core of hemoglobin in RBCs (60% of total iron body content). It is mainly stored (15% to 30% of total iron body content) inside the liver, spleen, and skeletal muscle as ferritin and in lysosomes as hemosiderin. The rest of the iron body content is trapped in myoglobin in skeletal muscle and cytochromes in mitochondria. In clinical practice, ferritin is a surrogate for iron stores, and total iron binding capacity (TIBC) is a surrogate for transferrin and the carrying capacity of iron.

Cells involved in the response to inflammatory insults cause the release of cytokines, such as IL-6, which stimulates hepatic release of hepcidin. Hepcidin is a circulating protein that blocks ferroportin, an iron channel responsible for the exit of iron from enterocytes (and thus gastrointestinal absorption) and macrophages (which accumulate iron from engulfed senescent blood cells). IL-1 and TNF-alpha stimulate IFN-gamma release by marrow stromal cells, which in turn suppress the erythroid response to erythropoietin (EPO). In chronic kidney disease, ACD is a consequence of decreased production of EPO and decreased renal clearance of hepcidin. The low availability of serum iron causes iron deficiency in the bone marrow compartment and decreased reticulocyte levels.

TABLE 1 Suspected Causes of Anemia of Chronic Disease

Shortened erythrocyte survival
Block in reuse of iron by erythrocyte
Direct inhibition of erythropoiesis
Relative deficiency of erythropoietin

From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

CLINICAL PRESENTATION

- Besides fatigue, shortness of breath, and generalized weakness from the anemia itself, it is important to consider other complaints if the underlying diagnosis is unknown, such as weight loss (malignancy, chronic infections, connective tissue diseases), anorexia, nausea, paresthesias, pleuritic chest pain, weight gain (CKD), diarrhea, bloody stools, abdominal pain, oral ulcers (IBD), and fevers (HIV, chronic infections).
- Physical findings may include pallor, lymphadenopathy, stigmatas of connective tissue diseases (malar rash, sclerodactyly), palpable or visible masses, and localized findings for infection or malignancy.

DIAGNOSIS

Isolated ACD:

- CBC with differential: Normocytic, normochromic, moderate (Hb rarely <8 g/dl) anemia
- Hypoproliferative anemia (low reticulocyte index; corrected reticulocyte count <2%)

Iron studies:

- Low iron concentration as in IDA (iron deficiency anemia)
- Normal/high ferritin (>35 mg/dl) in ACD as it is an acute phase reactant (Fig. 2)
- Low/normal TIBC (as opposed to IDA) and low transferrin saturation (as in IDA)
- Normal soluble transferrin receptor (sTfR, high in IDA)

Combined ACD/IDA:

- If normal to high ferritin, sTfR/log ferritin ratio <1 defines isolated ACD, and ratio >2 defines combined IDA/ACD

ETIOLOGY

- Malignancy
- CKD (patients with CKD stage IV [GFR<30 ml/min] should be screened for ACD)
- CHF (ACD is the main cause of anemia in CHF patients)
- Chronic infections
- Anemia of critical illness (develops within days)
- Connective tissue diseases

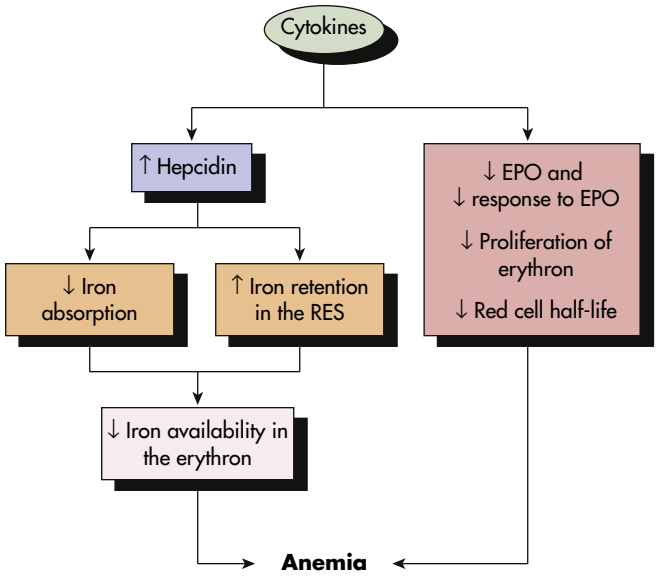

FIG. 1 Pathophysiologic factors associated with the development of anemia of chronic disease. *EPO,* Erythropoietin; *RES,* reticuloendothelial system. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

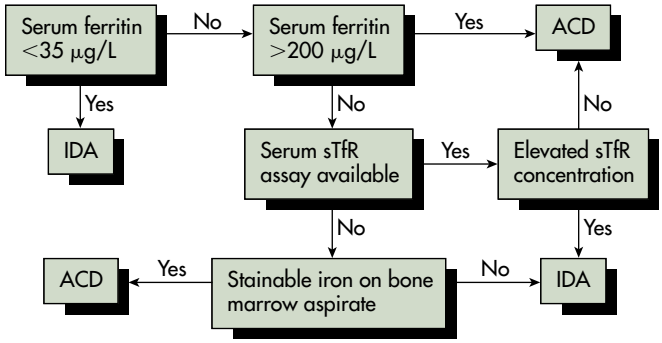

FIG. 2 Differential diagnosis of anemia with low serum iron. *ACD,* Anemia of chronic disease; *IDA,* iron deficiency anemia; *sTfR,* soluble transferrin receptor.

TABLE 3 Laboratory Characteristics of ACD, IDA, and IDA with Inflammation

	Anemia of Chronic Disease (ACD)	Iron Deficiency Anemia (IDA)	IDA with Inflammation
Mean corpuscular volume (MCV)	72-100 fL	<85 fL	<100 fL
Mean corpuscular hemoglobin concentration (MCHC)	<36 g/dl	<32 g/dl	<32 g/dl
Serum iron	Decreased	Decreased	Decreased
Serum total iron-binding capacity (TIBC)	Typical below mid-normal range	Elevated	Less than upper limit of normal range
Transferrin saturation*	2%-20%	<15% (usually <10%)	<15%
Serum ferritin	>35 μg/L	<35 μg/L	>35 μg/L, <200μg/L
Serum soluble transferrin receptor concentration (sTfR)	Normal (may be increased if serum ferritin >200 μg/L)	Increased	Increased
TfR index (sTfR/log ferritin)	<1	>2	>2
Hepcidin	High	Low	Normal
Stainable iron in bone marrow	Present	Absent	Absent

*Serum iron/TIBC * 100.

DIFFERENTIAL DIAGNOSIS

- Liver injury (increases ferritin):
  1. Iron deficiency anemia:
     a. Other causes of normocytic anemia or microcytic anemia (Table 2)
     b. Red blood cell loss or destruction:
        (1) Acute blood loss
        (2) Hypersplenism
        (3) Hemolysis
     c. Decreased red blood cell production:
        (1) Primary causes:
            (a) Bone marrow hypoplasia or aplasia
            (b) Myeloproliferative disease
            (c) Pure red blood cell aplasia
     d. Secondary causes:
        (1) Chronic renal failure
        (2) Liver disease
        (3) Endocrine deficiency states
        (4) Sideroblastic anemia

WORKUP

CBC, reticulocyte count, peripheral smear (Fig. E3), iron level, ferritin, TIBC. Table 3 summarizes characteristic findings in inflammatory anemia. Characteristic bone marrow findings of increased iron stores in stromal histiocytes and impaired erythroid iron incorporation are shown in Fig. E4.

Rx TREATMENT

Treat the underlying disorder/disease.

ACUTE GENERAL Rx

- The treatment of inflammatory anemia is directed primarily at treatment of underlying conditions, which can improve symptoms and facilitate hemoglobin recovery.
- Blood transfusion is usually reserved for severe anemia (with Hb level <7 g/dl or <8 g/dl in patients with cardiac disease), especially if complicated with ongoing bleeding.

CHRONIC Rx

- Erythropoiesis-stimulating agents (ESA) (epoetin alfa and darbepoetin alfa) are FDA approved for use in patients with anemia resulting from:
  1. Chronic kidney disease
  2. Chemotherapy
  3. Zidovudine therapy
- A 1998 study, the Normal Hematocrit Cardiac Trial (NHCT), showed a nonsignificant increase in the combined endpoint death and nonfatal MI in patients with goal hematocrit of 33% versus 27%. Subsequent studies (CHOIR, CREATE, and TREAT) showed that higher doses and higher hematocrit targets were associated with increased cardiovascular events.
- ESA dose should be individualized for each patient, and the lowest sufficient dose to reduce blood transfusions should be used. A hemoglobin target of approximately 10 g% is widely acceptable. Iron deficiency should be ruled out before ESA is started. After starting ESA therapy, ASH/ASCO guidelines recommend periodic monitoring of iron status. When there is no or suboptimal response to oral therapy, parenteral iron therapy should be considered before concluding that a patient is nonresponsive to iron therapy.
  - The hepcidin–ferroportin axis is the target of development of novel agents of which the most promising are hypoxia-induced factor modulators. HIF is a transcription factor that promotes expression of erythropoietin. HIF is upregulated by inhibition of PHD. Clinical trials of vadadustat, an oral hypoxia-inducible factor, in patients with anemia of kidney disease have demonstrated efficacy in achieving a hemoglobin of 11 g/dl or an increase of 1.2 g/dl. Also, mean hemoglobin levels were maintained in patients with CKD who were previously receiving ESA. Additional drugs in trials include oral inhibitors and antibodies and bone morphogenetic protein (BMP) receptor.

BASIC INFORMATION

DEFINITION

Anemia is defined as a hemoglobin level 2 standard deviations below normal for age and sex. Iron deficiency anemia is anemia resulting from inadequate iron supplementation or excessive blood loss.

ICD-10CM CODES	
D50.9	Iron deficiency anemia, unspecified
O99.019	Anemia complicating pregnancy, unspecified trimester
D50.0	Iron deficiency anemia secondary to blood loss (chronic)
D50.8	Other iron deficiency anemias

EPIDEMIOLOGY & DEMOGRAPHICS

- Dietary iron deficiency occurs often in infants as a result of unsupplemented milk diets. It is also commonly seen in women during their reproductive years, as a result of heavy menstrual periods, and during pregnancy (increased demand).
- Iron deficiency is the most common nutritional deficiency worldwide.
- The prevalence of iron deficiency is greatest among toddlers ages 1 to 2 yr (7%) from inadequate intake and female individuals ages 12 to 49 yr (9% to 16%) from menstrual losses.
- The prevalence of iron deficiency is 2% in adult men, 9% to 12% in non-Hispanic white women, and 20% in black and Mexican American women.
- GI cancer is diagnosed in 10% of elderly patients with iron deficiency anemia.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most patients have normal examination results.
- Skin pallor and conjunctival pallor may be present.
- Signs and symptoms specific for iron deficiency are koilonychias, pica, pagophagia, blue sclera, glossitis, and angular stomatitis (Fig. E1).
- Patients with severe anemia can have palpitations, headache, weakness, dizziness, and easy fatigability.

ETIOLOGY

- Blood loss from GI or menstrual bleeding (genitourinary blood loss less often the cause)
- Dietary iron deficiency (rare in adults)
- Poor iron absorption in patients with gastric or small-bowel surgery
- Repeated phlebotomy
- Increased requirements (e.g., during pregnancy)
- Other: Traumatic hemolysis (abnormally functioning cardiac valves), idiopathic pulmonary hemosiderosis (iron sequestration in pulmonary macrophages), paroxysmal nocturnal hemoglobinuria (intravascular hemolysis)
- The most common cause worldwide is hookworm infection

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anemia of chronic disease
- Sideroblastic anemia
- Thalassemia trait
- Lead poisoning

WORKUP

Diagnostic workup consists primarily of laboratory evaluation. Table 1 describes laboratory studies differentiating the most common microcytic anemias. Most patients with iron deficiency anemia are asymptomatic in the early stages. With progressive anemia, the major symptoms are fatigue, dizziness, exertional dyspnea, pagophagia (ice eating), and pica. Patient history may also suggest GI blood loss (melena, hematochezia, hemoptysis).

LABORATORY TESTS

- Laboratory results vary with the stage of deficiency.
- Absent iron marrow stores and decreased serum ferritin are the initial abnormalities.
- Decreased serum iron and increased total iron-binding capacity (TIBC) are the next abnormalities.
- Hypochromic microcytic anemia is present with significant iron deficiency.
- Peripheral smear in patients with iron deficiency generally reveals microcytic hypochromic red blood cells (Fig. E2) with a wide area of central pallor, anisocytosis, and poikilocytosis when severe.
- Laboratory abnormalities consistent with iron deficiency are low serum ferritin level, increased RBC distribution width with values generally >15, low mean corpuscular volume, low mean corpuscular hemoglobin, increased TIBC, and low serum iron.
- In patients diagnosed with iron deficiency anemia, a GI workup including an upper endoscopy and colonoscopy is recommended to look for source of iron loss.

TREATMENT

The goal of therapy is to supply sufficient iron to correct the low hemoglobin and replenish iron stores.

NONPHARMACOLOGIC THERAPY

Patients should be instructed to consume foods that contain large amounts of iron, such as liver, red meat, and legumes.

ACUTE GENERAL Rx

- Iron supplementation will result in reticulocytosis and will generally increase hemoglobin levels by 0.5 to 1 g per wk.
- Treatment consists of ferrous sulfate 325 mg PO daily for 3 to 6 mo. Doses higher than 325 mg/day are poorly tolerated. Calcium supplements can decrease iron absorption; therefore, these medications should be staggered. Supplemental vitamin C can increase oral absorption.
- Parenteral iron therapy is reserved for patients with poor tolerance, noncompliance with oral preparations, or malabsorption.
- Transfusion of packed RBCs is indicated in patients with severe symptomatic anemia.

CHRONIC Rx

Patients should be instructed to continue their iron supplements for at least 6 mo or longer to correct depleted body iron stores.

DISPOSITION

- Most patients respond rapidly to iron supplementation with improvement in CBC and general well-being (Table 2). GI side effects from oral iron therapy are common and may require decreased dosage to once every other day or to change to parenteral iron.
- A differential diagnosis of microcytic anemia that fails to respond to oral iron is described in Table 3.

REFERRAL

GI referral for evaluation of GI malignancy is recommended in all patients with iron deficiency and suspected GI blood loss.

TABLE 1 Laboratory Studies Differentiating the Most Common Microcytic Anemias

Study	Iron Deficiency Anemia	α or β Thalassemia	Anemia of Chronic Disease
Hemoglobin	Decreased	Decreased	Decreased
MCV	Decreased	Decreased	Normal-decreased
RDW	Increased	Normal	Normal-increased
RBC	Decreased	Normal-increased	Normal-decreased
Serum ferritin	Decreased	Normal	Increased
Total Fe binding capacity	Increased	Normal	Decreased
Transferrin saturation	Decreased	Normal	Decreased
FEP	Increased	Normal	Increased
Transferrin receptor	Increased	Normal	Increased
Reticulocyte hemoglobin concentration	Decreased	Normal	Normal-decreased

Fe, Ferritin; *FEP,* free erythrocyte protoporphyrin; *MCV,* mean corpuscular volume; *RBC,* red blood cell; *RDW,* red cell distribution width.

From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

TABLE 2 Responses to Iron Therapy in Iron Deficiency Anemia

Time after Iron Administration	Response
12-24 hr	Replacement of intracellular iron enzymes; subjective improvement; decreased irritability; increased appetite
36-48 hr	Initial bone marrow response; erythroid hyperplasia
48-72 hr	Reticulocytosis, peaking at 5-7 days
4-30 days	Increase in hemoglobin level
1-3 mo	Repletion of stores

From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

TABLE 3 Differential Diagnosis of Microcytic Anemia That Fails to Respond to Oral Iron

Poor compliance (true intolerance of iron is uncommon)

Incorrect dose or medication

Malabsorption of administered iron

Ongoing blood loss including gastrointestinal, menstrual, and pulmonary

Concurrent infection or inflammatory disorder inhibiting the response to iron

Concurrent vitamin B_{12} or folate deficiency

Diagnosis other than iron deficiency

- Thalassemias
- Hemoglobin C and E disorders
- Anemia of chronic disease
- Lead poisoning
- Sickle thalassemias, hemoglobin SC disease
- Rare microcytic anemias

From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

PEARLS & CONSIDERATIONS

COMMENTS

- Iron deficiency may impair aerobic performance and worsen symptoms in patients with heart failure. Treatment with IV iron in patients with chronic heart failure and iron deficiency has been shown to improve symptoms, quality of life, and functional capacity.
- If the diagnosis of iron deficiency anemia is made, locating the suspected site of iron loss is mandatory.

BASIC INFORMATION

DEFINITION

Pernicious anemia (PA) is an autoimmune disease resulting from antibodies against gastric intrinsic factor and gastric parietal cells.

SYNONYMS

Megaloblastic anemia resulting from vitamin B_{12} deficiency
Addison-Biermer anemia

ICD-10CM CODES

D51.0 Vitamin B_{12} deficiency anemia due to intrinsic factor deficiency
D51.8 Other vitamin B_{12} deficiency anemias
D51.9 Vitamin B_{12} deficiency anemia, unspecified
D51.1 Vitamin B_{12} deficiency anemia due to selective vitamin B_{12} malabsorption with proteinuria

EPIDEMIOLOGY & DEMOGRAPHICS

- Increased incidence in females and older adults (40 to 70 yr)
- More frequent in patients of northern European ancestry
- Overall prevalence of undiagnosed PA after age 60 yr is 1.9%
- Prevalence is higher in women (2.7%), particularly in black women (4.3%)
- Associated with other autoimmune diseases (e.g., type 1 diabetes mellitus, Graves disease, Addison disease), along with possible *Helicobacter pylori* association

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Mucosal pallor and/or glossitis
- Angular cheilosis
- Mild jaundice (representative of intramedullary hemolysis of megaloblastic cells); "lemon yellow" skin due to pallor and jaundice
- Peripheral sensory neuropathy with paresthesias initially and absent reflexes in advanced disease
- Delirium or dementia
- Worsening weakness and possible subacute combined degeneration of spinal cord (Fig. E1)
- Loss of proprioception and an unsteady gait
- Gastrointestinal symptoms including anorexia, pyrosis, nausea, and vomiting
- Possible splenomegaly and mild hepatomegaly

ETIOLOGY

- Parietal cell antibodies are present in >70% of patients, while intrinsic factor antibodies are noted in >50% of patients.
- Atrophic gastric mucosa (Fig. E2) with achlorhydria.
- Inborn errors of cobalamin-cofactor synthesis are rare. Fig. E3 illustrates the components and mechanism of cobalamin absorption. An etiopathophysiologic classification of cobalamin deficiency is described in Section II.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Nutritional vitamin B_{12} deficiency
- Malabsorption (e.g., celiac disease)
- Chronic alcoholism (multifactorial)
- Chronic gastritis related to *H. pylori* infection
- Folic acid deficiency
- Myelodysplasia
- Thyroid abnormalities
- Atrophic gastritis
- Paraproteinemias

WORKUP

- The clinical presentation of PA varies with the stage. Initially, patients may be asymptomatic. In advanced stages patients may have impaired memory, depression, gait disturbances, paresthesias, and generalized weakness.
- Investigation consists primarily of laboratory evaluation. Table 1 describes a step-wise approach to the diagnosis of cobalamin and folate deficiency.
- Endoscopy and biopsy for atrophic gastritis may be performed in selected cases.
- Diagnosis is crucial because failure to treat may result in irreversible neurologic deficits.

LABORATORY TESTS

- Complete blood count generally reveals macrocytic anemia, thrombocytopenia, and mild leukopenia with hypersegmented neutrophils (Fig. E4).
- Mean corpuscular volume (MCV) is significantly elevated in advanced stages.
- Reticulocyte count is low to normal.
- False low serum cobalamin levels can occur in patients who are pregnant or taking oral contraceptives, have multiple myeloma, have transcobalamin I (TCI) deficiency, have severe folic acid deficiency, or are taking large doses of ascorbic acid. False high normal levels in patients with cobalamin deficiency can occur in several conditions including hepatomas, severe liver disease, or monoblastic leukemias (Table 2).
- The absence of anemia or macrocytosis does not exclude the diagnosis of cobalamin deficiency. Anemia is absent in 20% of patients with cobalamin deficiency, and macrocytosis is absent in >30% of patients at the time of diagnosis. Macrocytosis can be masked by concurrent iron deficiency, anemia of chronic disease, or thalassemia trait.
- Laboratory tests used for detecting cobalamin deficiency in patients with normal vitamin B_{12} levels include serum and urinary methylmalonic acid (MMA) level (elevated), total homocysteine level (elevated), and intrinsic factor antibody (positive). Cobalamin is a cofactor for the enzymes L-methylmalonyl coenzyme A mutase and methionine synthase. Inadequate levels of cobalamin will thus result in increased MMA and homocysteine levels. Plasma MMA levels can also be used to differentiate cobalamin deficiency from folate deficiency because patients with folate deficiency have normal or mild elevations of MMA levels.
- An increased concentration of plasma MMA does not predict clinical manifestations of vitamin B_{12} deficiency and should not be used as the only marker for diagnosis of B_{12} deficiency.

TABLE 1 Stepwise Approach to the Diagnosis of Cobalamin and Folate Deficiency

Megaloblastic Anemia or Neurologic-Psychiatric Manifestations Consistent with Cobalamin Deficiency *Plus* Test Results on Serum Cobalamin and Serum Folate

Cobalamin[a] (pg/ml)	Folate[b] (ng/ml)	Provisional Diagnosis	Proceed with Metabolites?[c]
>300	>4	Cobalamin or folate deficiency is unlikely	No
<200	>4	Consistent with cobalamin deficiency	No
200-300	>4	Rule out cobalamin deficiency	Yes
>300	<2	Consistent with folate deficiency	No
<200	<2	Consistent with (1) combined cobalamin plus folate deficiency or (2) isolated folate deficiency	Yes
>300	2-4	Consistent with (1) folate deficiency or (2) an anemia unrelated to vitamin deficiency	Yes

Test Results on Metabolites: Serum Methylmalonic Acid and Total Homocysteine

Methylmalonic Acid (Normal, 70-270 nM)	Total Homocysteine (Normal, 5-14 μM)	Diagnosis
Increased	Increased	Cobalamin deficiency confirmed; folate deficiency still possible (i.e., combined cobalamin plus folate deficiency possible)
Normal	Increased	Folate deficiency is likely
Normal	Normal	Cobalamin and folate deficiency is excluded

[a]Serum cobalamin levels: Abnormally low, <200 pg/ml; clinically relevant low-normal range, 200-300 pg/ml.
[b]Serum folate levels: Abnormally low, <2 ng/ml; clinically relevant low-normal range, 2-4 ng/ml.
[c]Any frozen-over sample from serum folate/cobalamin determination can be subjected to metabolite tests.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, WB Saunders.

TABLE 2 Serum Cobalamin: False-Positive and False-Negative Test Results

Falsely Low Serum Cobalamin in the Absence of True Cobalamin Deficiency

- Folate deficiency (one third of patients)
- Multiple myeloma
- TCI deficiency
- Megadose vitamin C therapy
- Pregnancy
- Oral contraceptives

Falsely Raised Cobalamin Levels in the Presence of a True Deficiency[a]

- Cobalamin binders (TCI and II) increased (e.g., myeloproliferative states, hepatomas, and fibrolamellar hepatic tumors)
- TCII-producing macrophages are activated (e.g., autoimmune diseases, monoblastic leukemias and lymphomas)
- Release of cobalamin from hepatocytes (e.g., active liver disease)
- High serum anti-IF antibody titer

IF, Intrinsic factor; *TC,* transcobalamin.

[a]Although a low serum cobalamin level is not synonymous with cobalamin deficiency, 5% of patients with true cobalamin deficiency have low-normal cobalamin levels, a potentially serious problem because the patient's underlying cobalamin deficiency will progress if uncorrected.

From Hoffman R et al: *Hematology, basic principles and practice,* ed 6, Philadelphia, 2013, WB Saunders.

- Additional laboratory abnormalities can include elevated lactate dehydrogenase, direct hyperbilirubinemia, and decreased haptoglobin.
- Bone marrow aspirate is not necessary to diagnose cobalamin deficiency. It may show giant C-shaped neutrophil bands and megaloblastic normoblasts (Fig. E5).
- Schilling test: No longer used. It was historically used to identify the locus of cobalamin malabsorption and the cause of cobalamin deficiency.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Avoid folic acid supplementation without proper vitamin B_{12} supplementation. Folic acid supplementation alone may result in hematologic remission in patients with vitamin B_{12} deficiency but will not treat or prevent neurologic manifestations.

ACUTE GENERAL Rx

Traditional therapy of cobalamin deficiency consists of intramuscular (IM) or deep subcutaneous (SC) injections of vitamin B_{12} 1000 mcg/day for 1 wk, followed by 1000 mcg/mo, indefinitely. Monitor response and increase dosing if serum B_{12} levels decline.

CHRONIC Rx

- Parenteral vitamin B_{12} 1000 mcg/mo or intranasal cyanocobalamin 500 mcg/wk for the remainder of life.
- In patients who have no nervous system involvement, intranasal cyanocobalamin may be used in place of parenteral cyanocobalamin after hematologic parameters have returned to normal range. The initial dose of intranasal cyanocobalamin is 1 spray (500 mcg) in one nostril once per week. Nasal cyanocobalamin is expensive.
- Oral cobalamin (1000 to 2000 mcg/day) is also being effective in mild cases of pernicious anemia because approximately 1% of an oral dose is absorbed by passive diffusion, a pathway that does not require intrinsic factor. Cost for 1 mo of therapy is approximately $5. Consider returning to IM vitamin B_{12} supplementation if decline recurs.

DISPOSITION

Anemia generally resolves with appropriate cobalamin replacement therapy. Neurologic deficits, on the other hand, may be corrected only if treated early on.

REFERRAL

Gastroenterology referral for endoscopy on diagnosis of PA followed by periodic surveillance endoscopies to rule out gastric adenocarcinoma or carcinoid tumors.

PEARLS & CONSIDERATIONS

COMMENTS

- Early manifestations of negative cobalamin balance are increased serum methylmalonic acid and total homocysteine levels. This occurs when the total cobalamin in serum is still in the low-normal range.
- Vitamin B_{12} deficiency that is allowed to progress for longer than 3 mo may produce permanent degenerative lesions of the spinal cord (e.g., subacute combined degeneration of spinal cord).
- Vitamin B_{12} deficiency may suppress signs of polycythemia vera; treatment of B_{12} deficiency may unmask this disorder.
- Blunted or impeded therapeutic response to vitamin B_{12} may be due to concurrent iron or folic acid deficiency, uremia, infections, or use of drugs with bone marrow suppressant properties. Causes of megaloblastosis not responding to therapy with cobalamin or folate are summarized in Table 3.
- Drugs that interfere with B_{12} absorption include metformin, colchicine, neomycin, and aminosalicylic acid.
- Patients must understand that cobalamin replacement therapy is lifelong.
- Self-injection of vitamin B_{12} may be taught in selected patients. Cost of monthly injections is less than $10.
- Patients who have had bariatric surgery should receive 1 mg of oral vitamin B_{12} per day indefinitely.

TABLE 3 Causes of Megaloblastosis Not Responding to Therapy with Cobalamin or Folate

Wrong Diagnosis

Combined folate and cobalamin deficiencies being treated with only one vitamin

Associated iron deficiency

Associated hemoglobinopathy (e.g., sickle cell disease, thalassemia)

Associated anemia of chronic disease

Associated hypothyroidism

From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

Anemia, Sideroblastic

BASIC INFORMATION

DEFINITION

Sideroblastic anemias (SAs) are a heterogeneous group of blood disorders characterized by ring sideroblasts in the bone marrow (abnormal erythroblasts with pathologic iron deposits in the mitochondria distributed in a "ringlike" fashion around the nucleus) and impaired heme biosynthesis.

CLASSIFICATION (TABLE E1)

- Congenital sideroblastic anemia (CSA)
- Acquired clonal sideroblastic anemia (ACSA)
- Acquired reversible sideroblastic anemia (ARSA)
- Sideroblastic anemia

ICD-10CM CODES

D64.0	Hereditary sideroblastic anemia
D64.1	Secondary sideroblastic anemia due to disease
D64.2	Secondary sideroblastic anemia due to drugs and toxins
D64.3	Other sideroblastic anemias

EPIDEMIOLOGY & DEMOGRAPHICS

- X-linked (40% of CSAs); primarily affects males
- Autosomal recessive (15% of CSAs)
- ACSAs affect middle-aged and older adults

TABLE E1 Classification of Sideroblastic Anemias

Hereditary (Nonsyndromic)

- X-linked
- Autosomal dominant or recessive
- Acquired
- Idiopathic acquired[a] (refractory anemia with ring sideroblasts)
- Associated with previous chemotherapy, irradiation, or in transition myelodysplasia or myeloproliferative diseases

Drugs

- Alcohol
- Isoniazid
- Chloramphenicol
- Other drugs

Rare Causes

- Erythropoietic protoporphyria
- Copper deficiency or zinc overload
- Hypothermia

Hereditary (Syndromic)

- X-linked sideroblastic anemia with ring sideroblasts and cerebellar ataxia
- Myopathy, lactic acidosis, and sideroblastic anemia
- Pearson syndrome
- Thiamine-responsive megaloblastic anemia
- Sideroblastic anemia with immunodeficiency, fevers, and developmental delay

[a]Trial of pyridoxine indicated.

From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Symptoms of SA are similar to those of anemia and iron overload with additional features and variations noted based on the type.

- Mild to moderate anemia with other cytopenias
- Photosensitivity
- Hepatosplenomegaly
- Neurologic deficits
- Cardiomyopathy
- Pancreatic insufficiency
- Hepatic/renal failure

ETIOLOGY

- Congenital forms can be X-linked or autosomal recessive.
- Acquired clonal forms may be associated with chemotherapy or irradiation.
- RARS develops as a subtype of myelodysplasia.
- Reversible SA can be caused by alcohol, medications (isoniazid, pyrazinamide, cycloserine, chloramphenicol), thiamine deficiency, and copper deficiency.

DIAGNOSIS

The principal feature of SA is mild to moderate anemia in middle-aged or elderly patients, although severe anemias have been reported. SAs are usually microcytic, but normocytic and dimorphic smears are not uncommon. Symptoms of iron overload may be the presenting feature in some. History and clinical findings, together with typical laboratory evidence, usually permit accurate diagnosis of different types of SAs. Molecular defects can be identified in several hereditary forms and in some patients with acquired clonal SAs.

DIFFERENTIAL DIAGNOSIS

- SA must be differentiated from other causes of microcytic hypochromic anemia, including iron deficiency anemia, thalassemia, anemia of chronic disease, and lead poisoning.
- Tissue iron overload from SA may present similar to hereditary hemochromatosis with liver cirrhosis, diabetes, congestive heart failure, or cardiac arrhythmias.

WORKUP

- CBC, peripheral smear, iron studies, free erythrocyte protoporphyrin level, serum copper level, serum lead level, MRI, bone marrow aspiration and biopsy (Fig. E1).
- CBC counts reveal anemia, mostly moderate, although severe anemias have been reported.
- Microcytic, normocytic, or macrocytic and classic dimorphic anemias may be seen along with siderocytes with Pappenheimer bodies (mature hypochromic erythrocytes with basophilic iron deposits).
- High serum iron levels, low transferrin along with increased transferrin saturation and high serum ferritin.
- Bone marrow shows increased iron stores and the classic ring sideroblasts, not seen in normal bone marrow tissue. The ring sideroblasts represent pathologic iron deposits in the perinuclear mitochondria of erythroblasts.
- In transfusion-dependent anemias, monitoring of ferritin and transferrin saturation levels is essential to avoid iron overload.
- Features of ineffective erythropoiesis like increase in indirect bilirubin concentration, decrease in haptoglobin, increase in LDH, and normal or increase in reticulocyte number may be seen.
- MRI of posterior cranial fossa is indicated in anemia-ataxia syndromes.

TREATMENT

Treatment is directed at controlling symptoms of anemia and preventing organ damage from iron overload.

NONPHARMACOLOGIC THERAPY

Removal of toxic agents that are potentially predisposing to SA is necessary.

ACUTE GENERAL Rx

- A trial of pyridoxine (50 to 200 mg/day) is indicated for all patients with congenital SAs.
- 25% to 50% may show full or partial response to pyridoxine.
- Folic acid given along with pyridoxine ensures adequate substrate availability during increased hemoglobin synthesis.
- Patients who do not respond require support with PRBC transfusions.
- Chelation therapy is needed for patients with transfusion-dependent anemia to prevent complications of iron overload.
- Erythropoietin and granulocyte colony-stimulating factor use may show some success in treating myelodysplasia-associated refractory anemia with ring sideroblasts.
- Secondary SA caused by medications can be reversed by withdrawing the medication and administering vitamin B_6.

CHRONIC Rx

Organ dysfunction resulting from iron overload will require periodic phlebotomy to keep serum ferritin level <300 ng/ml, as long as the patient is not anemic.

- Iron chelating therapy for patients with moderate to severe anemia who require regular red cell transfusion: Deferoxamine is given as subcutaneous or intravenous infusion; deferiprone and deferasirox are given orally.
- Splenectomy should be avoided at all costs.
- Bone marrow transplant is a last resort in young patients who are pyridoxine resistant and transfusion dependent with iron overload.

PROGNOSIS

In patients with anemia alone, life expectancy is normal. In patients dependent on blood transfusions, morbidity from iron overload can be expected.

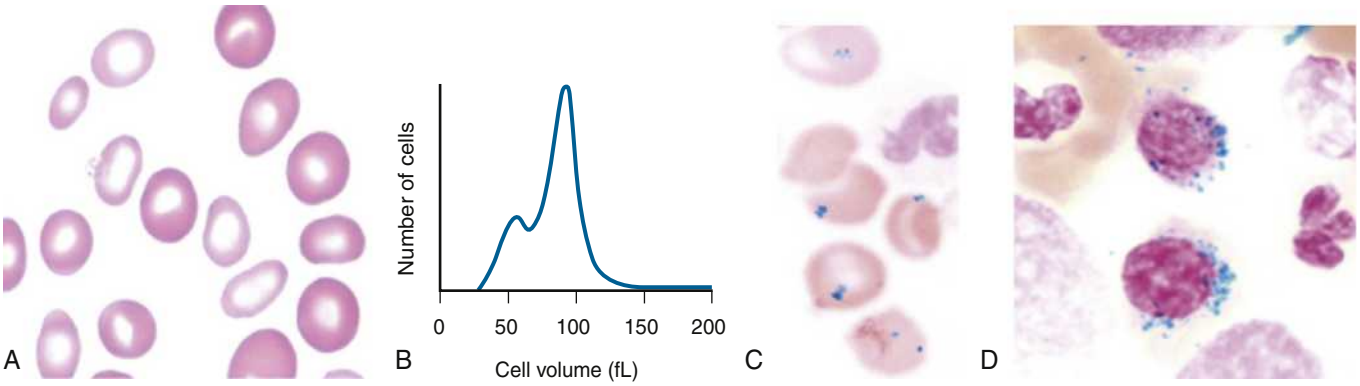

FIG. E1 **A,** Peripheral blood smear from a patient with hereditary sideroblastic anemia shows a population of hypochromic and microcytic erythrocytes. **B,** Erythrocyte volume distribution curve of a patient with hereditary sideroblastic anemia. A dimorphic size distribution is evident. **C,** Peripheral blood showing Pappenheimer bodies (Prussian blue stain). **D,** The bone marrow smear stained with Prussian blue shows ring sideroblasts. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

- RARS: With dysplasia confined to the erythroid cell lineage; survival similar to age-matched controls; no incidence of leukemic transformation.
- RCMD-RS: Approximately 5% will develop acute leukemia. Erythropoietin and granulocyte colony-stimulating factor therapy do not change survival.

REFERRAL

- Hematologist
- Neurologist (in anemia-ataxia and myopathy-anemia syndromes)
- Families with severe forms of hereditary sideroblastic anemia should receive genetic counseling

PEARLS & CONSIDERATIONS

- SA can be thought of as an iron-loading anemia secondary to defective heme synthesis.
- A predisposition to leukemia evolution has not been observed in patients with congenital forms.
- Symptoms rather than an absolute hemoglobin level or hematocrit should guide transfusion therapy.

COMMENTS

Vitamin B_6, or pyridoxal phosphate, is a required cofactor in heme synthesis, and drugs such as isoniazid, cycloserine, and pyrazinamide can inhibit its function.

Bottomley SS et al: Sideroblastic anemia: diagnosis and management, *Hematol Oncol Clin North Am* 28(4):653-670, 2014.

AUTHOR: **Shiva Kumar R. Mukkamalla, MD, MPH**

BASIC INFORMATION

DEFINITION

Angina pectoris is a term used to describe a clinical syndrome, typically characterized by chest, jaw, shoulder, back or arm discomfort that is caused by myocardial ischemia. This is most commonly related to atheromatous plaque in one or more than one large epicardial coronary artery; however, myocardial ischemia may occur in the absence of obstructive coronary artery disease (CAD), such as uncontrolled hypertension, microvascular disease, valvular heart disease, hypertrophic cardiomyopathy, coronary spasm, or endothelial dysfunction. Any situation that causes an imbalance in myocardial oxygen supply and demand can cause an angina syndrome. Angina can be classified as follows:

- Chronic stable angina, stable ischemic heart disease (SIHD), or chronic coronary artery disease:
  1. Predictable. Usually follows a precipitating event (e.g., climbing stairs, sexual intercourse, a heavy meal, emotional stress, cold weather).
  2. Generally has the same severity as previous attacks; relieved by rest or by the customary dose of sublingual nitroglycerin.
  3. Caused by a fixed coronary artery obstruction secondary to atherosclerosis. The presence of one or more obstructions in major coronary arteries is likely; the severity of stenosis is usually >70%.
- Unstable (rest, recent onset, crescendo angina; will be reviewed under Acute Coronary Syndrome):
  1. Rest angina: Angina occurring at rest and usually prolonged >20 min, occurring within 1 week of presentation.
  2. Recent onset: Angina of at least CCS Class III severity occurring less than 2 months after the onset of the symptoms.
  3. Crescendo angina: Previously diagnosed angina that is distinctly more frequent, longer in duration, or lower in threshold (i.e., increased by >1 CCS class within 2 months of initial presentation to at least CCS Class III severity).
- Prinzmetal variant:
  1. Occurs at rest, common after cold exposure.
  2. Cyclical in nature.
  3. EKG finding of episodic ST-segment elevations.
  4. Caused by coronary artery spasm with or without superimposed CAD.
  5. Patients are more likely to develop ventricular arrhythmias.
- Microvascular angina (syndrome X):
  1. Refers to patients with angina symptoms, positive exercise test, normal coronary angiograms and no coronary spasm. Defective endothelium-dependent dilation in the coronary microcirculation contributes to the altered regulation of myocardial perfusion and the ischemic manifestations in these patients.
  2. Patients with chest pain and normal or nonobstructive coronary angiograms are predominantly women, and many have a prognosis that is not as benign as commonly thought (2% risk of death or myocardial infarction [MI] at 30 days of follow-up).
- Refractory angina:
  1. Refers to patients whom, despite optimal medical therapy with at least maximal doses, or as tolerated of two antianginal medications, in addition to aspirin, aggressive risk factor modification, such as smoking cessation, adequate control of hypertension, diabetes, and hyperlipidemia, still have both angina and objective evidence of ischemia.
- Other:
  1. Angina due to aortic stenosis and idiopathic hypertrophic subaortic stenosis, cocaine-induced coronary vasoconstriction.

FUNCTIONAL CLASSIFICATION

Stable angina should be classified using a grading system. The most commonly adopted is that of the Canadian Cardiovascular Society (CCS):

- Class I: Ordinary physical activity, such as walking or climbing stairs, does not cause angina. Angina occurs with strenuous, rapid, or prolonged exertion at work or recreation.
- Class II: Slight limitation of ordinary activity. Angina occurs on walking or climbing stairs rapidly; walking uphill; walking or stair climbing after meals, in cold, in wind, or under emotional stress; or only during the few hours after awakening. Angina occurs on walking more than two level blocks and climbing more than one flight of ordinary stairs at a normal pace and in normal conditions.
- Class III: Marked limitations of ordinary physical activity. Angina occurs on walking one to two level blocks and climbing one flight of stairs in normal conditions and at a normal pace.
- Class IV: Inability to carry on any physical activity without discomfort; anginal symptoms may be present at rest.

ICD-10CM CODES

I20.8	Other forms of angina pectoris
I20.9	Angina pectoris, unspecified
I20.1	Angina pectoris with documented spasm
I25.110	Atherosclerotic heart disease of native coronary artery with unstable angina pectoris
I25.111	Atherosclerotic heart disease of native coronary artery with angina pectoris with documented spasm
I25.118	Atherosclerotic heart disease of native coronary artery with other forms of angina pectoris
I25.119	Atherosclerotic heart disease of native coronary artery with unspecified angina pectoris
I25.700	Atherosclerosis of coronary artery bypass graft(s), unspecified, with unstable angina pectoris
I25.790	Atherosclerosis of other coronary artery bypass graft(s) with unstable angina pectoris
I25.791	Atherosclerosis of other coronary artery bypass graft(s) with angina pectoris with documented spasm
I25.798	Atherosclerosis of other coronary artery bypass graft(s) with other forms of angina pectoris
I25.799	Atherosclerosis of other coronary artery bypass graft(s) with unspecified angina pectoris

EPIDEMIOLOGY & DEMOGRAPHICS

- It is estimated that one in three adults in the U.S. (about 81 million) has some form of cardiovascular disease. Based on the NHANES survey 2007-2010, an estimated 15.4 million have coronary heart disease of which 7.8 million have angina.
- Angina is most common in middle-aged and elderly men. Among persons 60 to 79 yr of age, approximately 25% of men and 16% of women have coronary heart disease, and these figures rise to 37% and 23% among men and women >80 yr of age, respectively.
- The incidence of coronary heart disease and angina in women after menopause is similar to that of men.
- Although the survival rate has steadily improved over time, SIHD remains the number one cause of death in men and women (27% of deaths).
- The initial manifestation of ischemic heart disease is angina pectoris in 50%, and about 50% of patients presenting to the hospital with acute coronary syndrome have preceding angina.
- Two older population-based studies from Olmstead County, MN, and Framingham, MA, showed annual rate of myocardial infarction in patients with symptomatic angina of 3 to 3.5%/yr.
- Within 12 months of initial diagnosis, 10% to 20% of patients with diagnosis of stable angina progress to MI or unstable angina.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The assessment of chest pain should include quality, location, severity, and duration of pain; radiation; associated symptoms; provocative factors; and alleviating factors. Anginal pain can be described as "squeezing," "griplike," "suffocating," and "heavy," but it is rarely sharp or stabbing and typically does not vary with position or respiration. The classic Levine sign is placing a clenched fist over the precordium to describe the pain. Many patients do not, however, describe angina as frank pain but as tightness, pressure, or discomfort. Other patients, in particular women and older adults, can present with atypical symptoms such as nausea, vomiting, midepigastric discomfort, sharp (atypical) chest pain, dizziness, or syncope.

- Ischemic pain of more than 20 minutes' duration should raise concern for possible acute coronary syndrome.
- Women are more likely than men to report atypical chest pain or discomfort (65% reported on Women's Ischemic Syndrome Evaluation [WISE] study).
- Elderly and diabetics may report symptoms other than chest pain, such as dyspnea, fatigue, or diaphoresis.

ETIOLOGY

RISK FACTORS:

- Advanced age
- Male sex
- Genetic predisposition, family history of premature coronary artery disease (CAD) in first-degree relatives (men younger than 55 yr of age, and women younger than 65 yr of age)
- Smoking (risk of first MI is increased by near threefold)
- Hypertension
- Hyperlipidemia
- Impaired glucose tolerance or diabetes mellitus
- History of stroke or peripheral arterial disease
- Chronic kidney disease (CKD)
- Metabolic syndrome
- Physical inactivity
- Obesity (body mass index >30% over ideal). A higher body mass index during childhood is also associated with an increased risk of coronary heart disease (CHD) in adulthood
- Entities that cause increased oxygen demand include hyperthermia (particularly if accompanied by volume contraction), hyperthyroidism, and cocaine or methamphetamine abuse
- Cocaine is used by >5 million Americans regularly and is responsible for >64,000 emergency department (ED) evaluations yearly to rule out myocardial ischemia. Cocaine causes sympathomimetic toxicity and not only increases myocardial oxygen demand but also induces coronary vasospasm and can cause infarction in young patients. Long-term cocaine use can cause premature development of SIHD
- Severe uncontrolled hypertension causes increased myocardial oxygen demand and decreased subendocardial perfusion that increases LV wall tension. Hypertrophic cardiomyopathy and aortic stenosis can induce even more severe LV hypertrophy and resultant wall tension
- Other causes of increased myocardial oxygen demand are ventricular or supraventricular tachycardias. Ambulatory monitoring may be required to diagnose these
- Entities that limit myocardial oxygen supply such as anemia may cause angina when the hemoglobin drops to <9 g/dl, and ST-T-wave changes (depression or inversion) can occur at levels <7 g/dl
- Hypoxemia resulting from pulmonary disease (e.g., pneumonia, asthma, chronic obstructive pulmonary disease, pulmonary hypertension, interstitial fibrosis, or obstructive sleep apnea) can also precipitate angina
- Polycythemia, leukemia, thrombocytosis, and hypergammaglobulinemia
- Oral contraceptive and HRT use
- Coronary artery calcium is associated with an increased risk of MI
- Long-term use of nonsteroidal antiinflammatory drugs (NSAIDs)
- Exposure to air pollution from traffic (dilute diesel exhaust) promotes myocardial ischemia and is associated with adverse cardiovascular events
- Low serum folate levels required for conversion of homocysteine to methionine are associated with an increased risk of fatal CHD. Hyperhomocysteinemia has a toxic effect on vascular endothelium and interferes with proliferation of arterial wall smooth muscle cells. Elevated plasma homocysteine level is a strong and independent risk factor for CHD events, especially in patients with type 2 diabetes mellitus
- Elevated levels of highly sensitive C-reactive protein (hs-CRP, cardio CRP). Diseases associated with systemic inflammation can lead to accelerated atherosclerosis
- Depression
- Vasculitis
- Elevated levels of lipoprotein-associated phospholipase A_2
- Elevated fibrinogen levels
- Low level of red blood cell glutathione peroxidase-1 activity
- Radiation therapy

DX DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Nonischemic cardiovascular:** Aortic dissection, pericarditis
- **Pulmonary:** Pulmonary embolism, pneumothorax, pneumonia, pleuritis
- **Gastrointestinal:** Esophageal, esophagitis, spasm, reflux, biliary colic, cholecystitis, choledocholithiasis, cholangitis, peptic ulcer, pancreatitis
- **Chest wall:** Costochondritis, fibrositis, rib fracture, sternoclavicular arthritis, herpes zoster (before the rash)
- **Psychiatric:** Anxiety disorders, hyperventilation, panic disorder, primary anxiety, affective disorders (i.e., depression), somatoform disorders, thought disorders (i.e., fixed delusions)

WORKUP

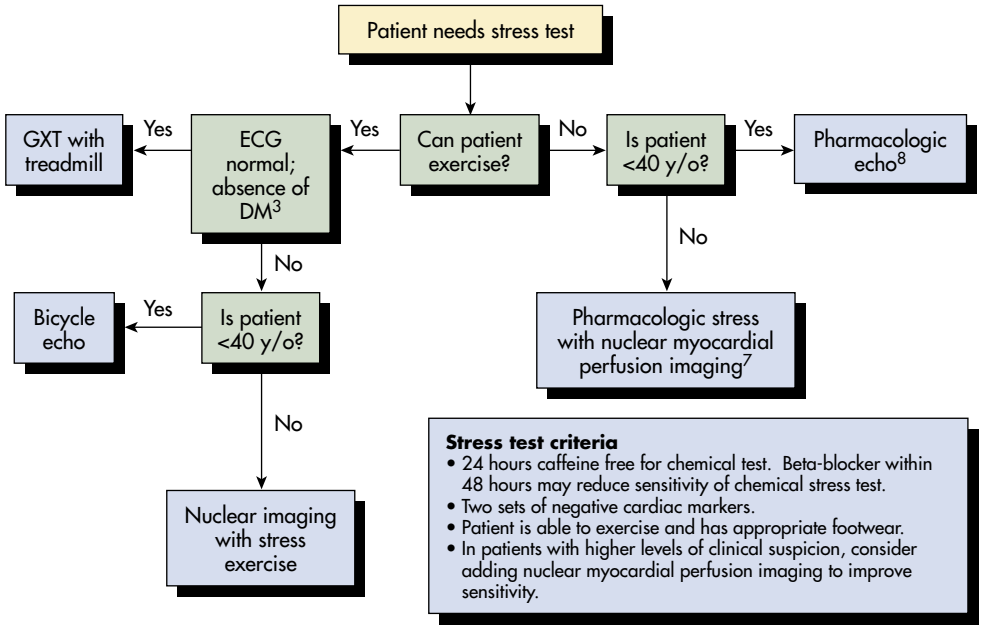
- In patients with chest pain, the probability of CAD should be estimated on the basis of patient age, sex, cardiovascular risk factors, and pain characteristics.
- The most important diagnostic element is the history. Chest pain or left arm pain or discomfort occurring with exertion and relieved by rest in a patient with cardiovascular risk factors is consistent with a high likelihood of CAD.
- In assessing the likelihood of underlying SIHD it is helpful to classify the chest pain as typical angina, atypical angina, and/or noncardiac chest pain.
- Typical angina, (definite) will have the following three features: (1) Substernal chest discomfort with a characteristic quality and duration, (2) provoked by exertion or emotional stress, and (3) relieved by rest and/or sublingual nitroglycerin (NTG).
- Atypical angina, (probable) will have two of the above listed three features.
- Noncardiac chest pain will have one or none of the previously listed features.
- Physical examination may be completely normal in many patients; however, certain findings may be helpful in the assessment of the patient with suspected SIHD. Some findings may identify consequences of ischemia or possible causes of the anginal syndrome other than CAD. The presence of hypertension, arcus senilis, xanthelasma, carotid or peripheral bruits, and a prominent S4 are all physical signs that could raise concern for the presence of CAD. A murmur of mitral regurgitation may be a marker of an ischemic cardiomyopathy or transient ischemia. A murmur suggestive of hypertrophic cardiomyopathy or aortic stenosis may suggest a cause of angina other than CAD.
- The ultimate goal for an SIHD patient's evaluation is to identify high-risk coronary artery disease patients with minimal use of resources. In general, four common steps would help a clinician to assess high feature of SIHD. Those are (1) CAD risk assessment based on various classical risk factors, (2) functional capacity and stress test result, (3) LV and RV function, and (4) coronary anatomy. Every patient does not need each of the modalities. One should classify stable angina without history of CAD patients to low, intermediate, and high pretest probability or likelihood for CAD after assessment of comorbidities. Consider functional capacity and stress test (ETT, ETT-MIBI, or Stress echo) for low and intermediate pretest probability patients. Exercise testing (Fig. 1) is preferred to pharmacologic stress tests when possible. Functional capacity and stress test results categorize SIHD patients based on their risk of annual mortality. Patients with an estimated annual mortality of <1% classify as low risk, 1% to 3% are considered as intermediate risk, and >3% annual mortality belongs to high-risk patient population (please see "Coronary Artery Disease" chapter).

LABORATORY TESTS

- Screen for hypertension, diabetes, and hyperlipidemia per routine guidelines.
- Electrocardiogram should be obtained during pain and when the patient is free of any discomfort. A normal resting electrocardiogram is not unusual in patients with SIHD; in patients who present with chest pain, 1% to 6% who have an acute MI will have a normal or nondiagnostic electrocardiogram.
- Chest x-ray PA and lateral, if symptoms suggestive of heart failure, pericardial disease, aortic aneurysm/dissection.
- Cardio-CRP (hs-CRP): Its elevation is a relatively moderate predictor of CHD, and it adds prognostic information to that conveyed by the Framingham risk score.

EXERCISE TESTING AND IMAGING STUDIES (PLEASE SEE "CORONARY ARTERY DISEASE" CHAPTER, FIG. 1)

- Exercise testing is used for diagnosis as well as prognosis of SIHD. If the patient is physically capable to perform at least moderate physical exercise, exercise stress testing (Fig. 1) is useful because of the important prognostic information obtained from exercise performance and the hemodynamic response. Risk stratification based on non-invasive testing is summarized in Table 1. Patients who have an intermediate likelihood of CAD, as patients in a low-risk or high-likelihood category are more likely to have a false-positive or false-negative result, respectively. Risk assessment is also indicated in patients with SIHD who are being considered for revascularization of known coronary stenosis of unclear physiological significance. The exercise treadmill test is contraindicated in patients with presence of ST depression >0.5 mm or WPW syndrome or LBBB or pacemaker rhythm in baseline ECG.
- Stress echocardiography or stress testing with myocardial perfusion imaging may be employed when baseline electrocardiographic abnormalities are present that render the electrocardiographic response to exercise uninterpretable. Stress echocardiography has the advantage of higher specificity and a lower cost. Stress radionuclide perfusion imaging has a higher sensitivity, particularly for single-vessel coronary disease, and has a higher technical success rate. When the patient is unable to exercise adequately, pharmacologic stress testing



DEFINITIONS:

[1]Typical angina:
(1) Substernal chest pain or discomfort that is (2) provoked by exertion or emotional stress and (3) relieved by rest and/or nitroglycerin

[2]Cardiac marker timing: based on symptom onset; in cases of uncertainty assume symptom onset at ED arrival

[3]ECG normal: no significant ST depression/T wave inversions, BBB, LVH with repolarization, conduction defect, digoxin effect

[4]Anginal equivalent:
- Any symptoms that the physician feels may represent ACS
- Exertional dyspnea—most common anginal equivalent symptom

[5]ACS:
- STE-ACS—1 mm ST elevation in 2 leads
- NSTE-ACS
  - NSTEMI—positive cardiac biomarkers
  - Unstable angina—ischemia with negative biomarkers

[6]New significant ECG changes:
- ST Δs ≥ 0.5 mm; resolve when asymptomatic
- ST depression ≥1 mm in 2 leads
- T wave inversion ≥2 mm in 2 leads

[7]Regadenoson is preferred agent for chemical nuclear stress test. Technitium Tc 99m tetrofosmin is the preferred tracer.

FIG. 1 Stress test algorithm. *ACS,* Acute coronary syndrome; *BBB,* bundle branch block; *DM,* diabetes mellitus; *ECG,* electrocardiogram; *echo,* echocardiography; *ED,* emergency department; *GTX,* graded exercise test; *LVH,* left ventricular hypertrophy; *NSTE,* non–ST-segment elevation; *NSTEMI,* NSTE myocardial infarction; *STE,* ST-segment elevation; *y/o,* years old. (From Adams JG et al: *Emergency medicine: clinical essentials,* ed 2, Philadelphia, 2013, Saunders.)

TABLE 1 Risk Stratification Based on Noninvasive Testing

High Risk (>3% Annual Risk for Death or Myocardial Infarction)

1. Severe resting left ventricular dysfunction (LVEF <35%) not readily explained by noncoronary causes
2. Resting perfusion abnormalities involving ≥10% of the myocardium without previous known MI
3. High-risk stress findings on the ECG, including
   - ≥2-mm ST-segment depression at low workload or persisting into recovery
   - Exercise-induced ST-segment elevation
   - Exercise-induced VT/VF
4. Severe stress-induced LV dysfunction (peak exercise LVEF <45% or drop in LVEF with stress ≥10%)
5. Stress-induced perfusion abnormalities encumbering ≥10% of the myocardium or stress segmental scores indicating multiple vascular territories with abnormalities
6. Stress-induced LV dilation
7. Inducible wall motion abnormality (involving >2 segments or 2 coronary beds)
8. Wall motion abnormality developing at a low dose of dobutamine (≤10 mg/kg/min) or at a low heart rate (<120 beats/min)
9. Multivessel obstructive CAD (≥70% stenosis) or left main stenosis (≥50% stenosis) on CCTA

Intermediate Risk (1%-3% Annual Risk for Death or Myocardial Infarction)

1. Mild to moderate resting LV dysfunction (LVEF of 35% to 49%) not readily explained by noncoronary causes
2. Resting perfusion abnormalities involving 5%-9.9% of the myocardium in patients without a history or previous evidence of MI
3. ≥1-mm ST-segment depression occurring with exertional symptoms
4. Stress-induced perfusion abnormalities encumbering 5%-9.9% of the myocardium or stress segmental scores indicating 1 vascular territory with abnormalities but without LV dilation
5. Small wall motion abnormality involving 1-2 segments and only 1 coronary bed
6. 1-vessel CAD with ≥70% stenosis or moderate CAD stenosis (50%-69% stenosis) in ≥2 arteries on CCTA

Low Risk (<1% Annual Risk for Death or Myocardial Infarction)

1. Low-risk treadmill score (score ≥5) or no new ST-segment changes or exercise-induced chest pain symptoms when achieving maximal levels of exercise
2. Normal or small myocardial perfusion defect at rest or with stress encumbering <5% of the myocardium*
3. Normal stress or no change in limited resting wall motion abnormalities during stress
4. No coronary stenosis >50% on CCTA

CCTA, Cardiac computed tomography angiography; *LVEF,* left ventricular ejection fraction; *VF,* ventricular fibrillation; *VT,* ventricular tachycardia.
*Although the published data are limited, patients with these findings will probably not be at low risk in the presence of either a high-risk treadmill score or severe resting LV dysfunction (LVEF <35%). Assessment of coronary artery calcium (CAC) can also be used to contribute to risk assessment.
Modified from Fihn SD et al: ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines, and the American College of Physicians, American Association for Thoracic Surgery, Preventive Cardiovascular Nurses Association, Society for Cardiovascular Angiography and Interventions, and Society of Thoracic Surgeons, *Circulation* 126:e354, 2012; in Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

(i.e., dobutamine, adenosine, regadenoson) may be used with these imaging modalities.

- A good predictor of risk for a patient with stable angina is the Duke treadmill score, which incorporates the patient's functional status (METS or time in minutes during the Bruce protocol), ST-segment depression in millimeters, and an angina index (yes or no). Patients with favorable Duke scores (>5) have a 5-yr survival rate of >97%; this is independent of other factors such as coronary anatomy and LV function.
- Echocardiography is indicated in patients with murmurs suggestive of aortic stenosis, hypertrophic cardiomyopathy, mitral regurgitation, mitral valve prolapse, previous MI, pathological Q waves, complex ventricular arrhythmias, heart failure, hypertension, diabetes, and abnormal EKG.
- Cardiac computed tomography (CCTA; Fig. 2) is useful for the detection of subclinical CAD in asymptomatic patients with an intermediate Framingham 10-yr risk estimate of 10% to 20%. Detects and quantifies coronary calcium and evaluates the lumen and wall of the coronary artery. CCTA can be useful as a first-line test for risk assessment in patients with SIHD who are unable to exercise to an adequate workload regardless of interpretability of ECG. Also can be used when a functional test has an indeterminate result and to assess bypass graft patency or patency of previous stents >3 mm diameter. CCTA CT cost and radiation exposure are limiting factors to recommending widespread routine use of this marker. CCTA has an excellent negative predictive value to rule out severe CAD in the setting of active chest pain evaluation in the emergency room (ROMICAT-II trial). In 2018 the SCOT-HEART trial showed coronary CTA resulted in a lower risk of nonfatal myocardial infarction than standard care alone (ETT) in stable angina patients.
- Coronary artery calcium (CAC) score is a strong predictor of incidence of CAD and provides predictive information in patients with low to intermediate pretest probability of CAD beyond that provided by standard risk factors. A score below 100 indicates low risk, and a score above 400 high risk.
- Cardiac magnetic resonance imaging (CMRA), in addition to its use for diagnosis of arrhythmogenic right ventricular dysplasia, can also be used to assess myocardial perfusion and viability as well as function in patients unable to exercise. Additional studies are needed to determine the cost effectiveness of these studies in patients with ischemic cardiomyopathy.
- Invasive coronary angiography remains the gold standard for the identification of clinically significant CAD. Angiography is performed to define the location and extent of coronary disease; indicated in selected patients who are candidates for coronary revascularization (either coronary artery bypass graft [CABG] surgery or angioplasty).

Rx TREATMENT

FIVE FUNDAMENTAL OVERLAPPING STRATEGIES ARE RECOMMENDED

- Patient education: Support active participation of patients in the decision-making process of their treatment.
- Management of comorbid conditions that contribute or worsen SIHD.
- Aggressive modification of preventable risk factors such as smoking cessation, weight reduction in obese patients, regular aerobic exercise program (at least 30 to 60 min/day for 5 days a week), correction of folate deficiency, reduced intake of saturated fats (to <7% of total calories) and trans fatty acids (to <1% of total calories), low-sodium diet (<2 g/day), and teaching importance of medication adherence. Whole grains as the main form of carbohydrates, an abundance of fruits and vegetables, and adequate omega-3 fatty acids are optimal for prevention of SIHD.

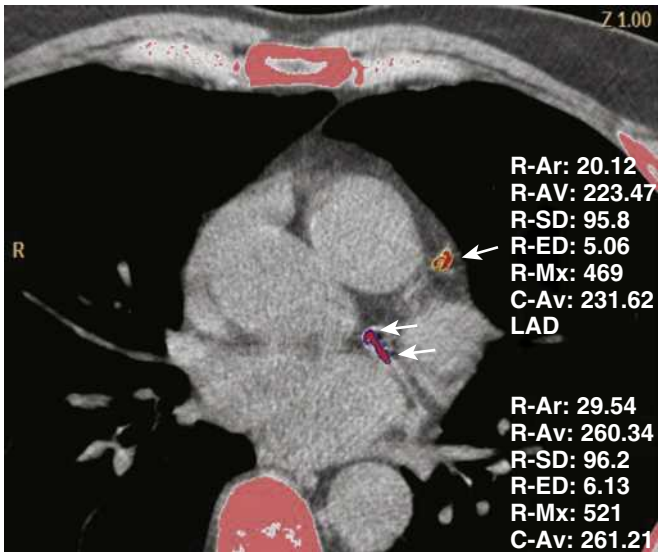


FIG. 2 Example of coronary artery calcium scoring in which calcified foci are identified within the left anterior descending *(orange; single arrow)* and left circumflex *(pink outlined in blue; double arrow)* coronary arteries. The region's area *(R-Ar)* and its average density in Hounsfield units *(R-Av)* are displayed and used in the area-density calcium scoring calculation. (From Bonow RO et al: *Heart disease,* ed 9, Philadelphia, 2012, Saunders.)

- Evidence-based pharmacologic management to improve quality of life and survival.
- Use appropriate revascularization procedures to improve survival and long-term outcomes in selected patients.

PHARMACOLOGIC THERAPY (PLEASE SEE "CORONARY ARTERY DISEASE" CHAPTER)

Treatment can be classified based on medications that prevent MI and death.

- Aspirin reduces cardiovascular mortality and morbidity rates by 20% to 25% among patients with CAD. Appropriate dose is 75 to 162 mg/day in the absence of contraindications. It inhibits the enzyme cyclooxygenase and synthesis of thromboxane A2 and reduces the risk of adverse cardiovascular events by 33% in patients with unstable angina. Patients intolerant to aspirin can be treated with clopidogrel or can undergo aspirin desensitization. Clopidogrel irreversibly blocks the P2Y12 adenosine diphosphate receptor on the platelet surface, thereby interrupting platelet activation and aggregation. Clopidogrel can be combined with ASA in high-risk patients with SIHD with low risk for bleeding complications or can be given alone in patients that are aspirin intolerant. Dose is 75 mg/day.
- Ticagrelor, the newest CTPT inhibitor (P2Y12 antagonist), in the PEGASUS-TIMI-54 reduced the risk of death, cardiovascular MI, or stroke in patients after 1 yr of MI. However, it is associated with an increased risk of bleeding when compared to placebo.
- Dipyridamole is not recommended as an antiplatelet therapy for the treatment of patients with SIHD.
- Beta-adrenergic blockers, which prevent MI and death, are first-line therapy in the management of angina pectoris. They achieve their major antianginal effect by decreasing myocardial oxygen demand in reducing heart rate and systolic blood pressure product, AV nodal conduction, and myocardial contractility, in this manner contributing to a reduction in angina onset, with improvement in the ischemic threshold during exercise and during the usual daily activities. Absent contraindications, they should be regarded as initial therapy for stable angina for all patients. Their dose should generally be adjusted to reduce the resting heart rate to 55 to 60 beats/min. Despite the difference among the available beta-blockers, they all seem to be equally efficacious in SIHD. Beta-blockers recommended for at least 2 to 3 yr after MI, and lifelong for patients with LV ejection fraction of <40% with heart failure or prior MI.
- Nitrates cause venodilation and relaxation of vascular smooth muscle; the decreased venous return from venodilation decreases diastolic ventricular wall tension (preload) and thereby reduces mechanical activity (and myocardial oxygen consumption) during systole. Relaxation of vascular smooth muscle increases coronary blood flow and reduces systemic pressure. Dilatation of the arterial wall will not be affected by plaque, but independent of an intact endothelium, leads to reduced resistance across the obstructed lumen. Nitroglycerin contributes to coronary blood flow redistribution by augmenting collateral flow and lowering ventricular diastolic pressure from areas of normal perfusion to ischemic zones. Nitroglycerin also has demonstrated antithrombotic and antiplatelet effects. Sublingual nitroglycerin or nitroglycerin spray should be prescribed to all patients with SIHD for immediate angina relief. Tolerance to nitrates can be minimized by avoiding sustained blood levels with a daily nitrate-free period (e.g., omission of bedtime dose of oral isosorbide dinitrate or 12 hr on/12 hr off transdermal nitroglycerin therapy). Nitrates are relatively contraindicated in patients with hypertrophic obstructive cardiomyopathy, and should also be avoided in patients with severe aortic stenosis. Nitrates should not be used within 24 hr of sildenafil (Viagra) or vardenafil (Levitra) or within 48 hr of tadalafil (Cialis) because of the potential for hypotension.
- Calcium channel blockers are antiischemic medications that have no proven mortality benefit in SIHD. They improve myocardial oxygen supply by decreasing coronary vascular resistance and augmenting epicardial conduit vessel and systemic arterial blood flow. Myocardial demand is decreased by a reduction in myocardial contractility, systemic vascular resistance, and arterial pressure. They are first-line treatment when beta-blockers are contraindicated. They play a major role in preventing and terminating myocardial ischemia induced by coronary artery spasm. They are particularly effective in treating microvascular angina. All classes of calcium channel blockers reduce anginal episodes, increase exercise duration, and reduce use of sublingual nitroglycerin in patients with effort-induced angina. Short-acting calcium channel blockers should be avoided. Calcium channel blockers (particularly non-dihydropyridine) should generally also be avoided in patients with CHF secondary to systolic dysfunction due to its negative inotropic effect.
- Ranolazine, which has been tested in four different studies with a total of 1737 patients (MARISA, CARISA, RAN080, and ERICA), inhibits the late inward sodium current, indirectly reducing the sodium-dependent calcium current during ischemic conditions and leading to improvement in ventricular diastolic

tension and oxygen consumption. It seems to increase the efficiency of energy production in the heart, maintaining cardiac function. Its antianginal and antiischemic effects do not depend on reductions in heart rate or blood pressure. It is indicated for treatment of chronic angina that is inadequately controlled with other antianginals. It represents a new class of drugs known as metabolic modulators and can be useful when prescribed as substitute for beta-blockers or in combination with them for relief of symptoms when initial treatment with beta-blockers is not successful or is contraindicated. Side effects include prolongation of QT interval. Low doses of diltiazem and verapamil should be used with ranolazine. The extended-release preparation reduces the frequency of angina, improves exercise performance, and delays the development of exercise-induced angina and ST-segment depression.

- Angiotensin-converting enzyme (ACE) inhibition through changes in the physiologic balance between angiotensin II and bradykinin could contribute to the reductions in LV and vascular hypertrophy, atherosclerosis progression, plaque rupture, and thrombosis; the favorable changes in cardiac hemodynamics; and the improved myocardial oxygen supply/demand. It has been shown to be effective in reducing cardiovascular death, MI, and stroke in patients who are at risk for or who had vascular disease. They are indicated in patients with hypertension, diabetes, LVEF <40%, and CKD. Angiotensin receptor blockers (ARBs) can be given to patients with SIHD who are intolerant to ACEI and qualify for them.
- Use of high-intensity statin drugs is recommended in all patients with CAD. In late 2018 the American College of Cardiology (ACC) recommended an LDL goal of <70 mg/dl for secondary prevention of atherosclerotic cardiovascular disease. There is no LDL goal for primary prevention. The FDA approved PCSK9 (proprotein convertase subtilisin/kexin type 9) inhibitors (Alirocumab and Evolocumab) for heterozygous familial hypercholesterolemia in those who maximally tolerated statins. Newer 2018 lipid guidelines suggested starting PCSK9 inhibitor in very-high-risk atherosclerotic cardiovascular disease patients who did not meet the LDL goal on high-intensity statin and ezetimibe. One should always consider adding ezetimibe to high-intensity statin prior to initiation of PCSK9 inhibitor due to cost issues.
- Influenza vaccine is recommended for patients with SIHD on annual basis to prevent all-cause mortality, morbidity, and hospitalization caused by the exacerbation of underlying medical conditions produced by influenza.

NEW MODALITIES FOR THE TREATMENT OF CHRONIC STABLE ANGINA PECTORIS

- Although a significant amount of progress has been made in the management of CAD with percutaneous coronary intervention (PCI) and CABG, many patients with the condition require additional therapeutic modalities for relief of symptoms and improvement in quality of life. This group of patients includes those with diffuse CAD who are not suitable for revascularization, patients with previous multiple PCIs or CABG limiting the chances for further revascularization, the lack of vascular conduits for CABG, severe left ventricular systolic dysfunction in patients with previous CABG or PCI, and comorbidities that would render the patients at high risk for revascularization.
- The following pharmacologic agents have been used for the management of stable angina in combination with the standard protocol of nitrates, beta-blockers, calcium channel blockers, and ranolazine: High-dose statin therapy, trimetazidine, perhexiline, nicorandil, allopurinol, ivabradine, fasudil, and testosterone.
- Other, nonpharmacologic modalities that are highly experimental include stem cell therapy, therapeutic angiogenesis, and mechanical therapies like external counterpulsation, spinal cord stimulation, transmyocardial laser revascularization, and coronary sinus reducing device.
- In TACT (Trial to Assess Chelation Therapy), Ethylenediaminetetraacetic acid (EDTA) intravenous infusion resulted significant decrease in total mortality, recurrent MI, stroke, coronary revascularization, or hospitalization for angina. Thus chelation therapy was upgraded from Class III (not recommended) to Class IIb in the 2014 SIHD guidelines. Allopurinol, a xanthine oxidase inhibitor, was shown to reduce myocardial oxygen demand per unit of cardiac output in patients with heart failure in a small crossover study of 65 patients given 600 mg of allopurinol daily for 6 weeks. Allopurinol increased the median time to ST depression from 232 seconds at baseline to 393 seconds. Further and larger studies are necessary to recommend allopurinol as an adjunctive therapy for stable angina.
- Testosterone improves endothelial dysfunction and may be an effective antiangina agent. However, given the potential side effects, additional trials are necessary to recommend testosterone as an adjunctive drug for chronic angina.

The value of enhanced external counterpulsation, or EECP, was assessed with the MUST-EECP trial, which randomly assigned 139 outpatients with angina, documented CAD, and a positive stress test to 35 hours of active EECP. The results indicated the following regarding EECP: (1) Was well tolerated; (2) exercise duration increased in both groups; (3) active EECP patients had a significant increase in time to 1-mm ST-segment depression, while there was no change in the inactive group; (4) more patients undergoing active EECP had a decrease in angina episodes, and fewer had an increase in angina symptoms compared with the active group. These data corroborate similar data from multicenter registries. The American Heart Association, American College of Cardiology, Society for Cardiovascular Angiography and Interventions, American Thoracic Society, and Society of Thoracic Surgeons focused update states that EECP may be considered for relief of refractory angina.

The following treatments have NOT been shown to be beneficial in reducing cardiovascular risk or improving clinical outcomes: Estrogen therapy, vitamin C, vitamin E, and beta-carotene supplementation; treatment of elevated homocysteine with folate or vitamins B_6 and B_{12}; chelation therapy; garlic; coenzyme Q10; selenium; and chromium.

REFERRAL

Revascularization:

- Revascularization methods should be formulated taking into consideration improved survival or improved symptoms. Revascularization includes either percutaneous coronary intervention (balloon angioplasty and stenting) or CABG. However, note that although the role of PCI is unquestionable in the presence of an acute myocardial infarction, its role is not so clear in stable CAD. The utilization of PCI for stable CAD was reduced by 51.7% from 2007 to 2011, and hospitals with higher volumes of PCI had the largest reduction of these procedures.
- **To improve survival:**
  1. Perform CABG for patients with significant (>50% diameter stenosis) left main coronary artery stenosis, more than 70% diameter stenosis in proximal left anterior descending artery (LAD), or more than 70% diameter stenosis in three major epicardial vessels, >70% diameter stenosis in two major coronary arteries with severe or extensive myocardial ischemia, and in patients with mild to moderate LV systolic dysfunction (EF 35% to 50%) and significant multivessel CAD. Left internal mammary artery (LIMA) graft improves survival when used to bypass a proximal LAD artery stenosis. CABG is recommended in preference to PCI to improve survival in patients with multivessel CAD and diabetes, particularly if a LIMA graft to LAD is used.
  2. PCI is reasonable as an alternative to CABG in selected stable patients (low or intermediate SYNTAX score and[or] high STS score) with unprotected left main CAD, low risk of PCI procedural complications, and a high likelihood of good long-term outcome *and* clinical characteristics that predict a significantly increased risk of adverse surgical outcomes (e.g., STS-predicted risk of operative mortality >5).
- **To improve symptoms:**
  1. CABG or PCI to improve symptoms is beneficial in patients with one or more significant (>70% diameter) coronary artery stenosis amenable to revascularization and unacceptable angina despite maximal medical treatment, or in whom increasing medical therapy cannot be implemented because of medication contraindications,

adverse effects, or patient preferences. In 2017, ORBITA trial showed no significant improvement in angina score after PCI for optimally treated stable angina patients. However, 85% of study patients in placebo group underwent PCI within 6 weeks after ORBITA trial completed.

2. Hybrid coronary revascularization: LIMA-to-LAD artery grafting and of >1 non-LAD coronary artery can be used in patients who have an unfavorable aorta, have poor target vessels for CABG, have unsuitable graft conduits, or have unfavorable LAD for PCI.

- Compared with percutaneous coronary intervention (PCI), CABG is more effective in relieving angina and leads to fewer repeated revascularizations but has a higher risk for procedural stroke. Survival to 10 yr is similar for both procedures.
- Angioplasty and coronary stents (Fig. E3).
- PCI has an established place in treating angina but is not superior to intensive medical therapy to prevent MI and death in symptomatic or asymptomatic patients. Patients selected for PCI should also be candidates for CABG. Approximately 80% of patients show immediate benefit after PCI. The development of coronary stents has increased the number of patients who can be treated in the cardiac laboratory. Cardiac stents (Fig. E4) are currently used in nearly 95% of all patients with PCI lesions. The rate of restenosis is reduced by placing a stent electively in primary atheromatous lesions. The major limitations of stenting are subacute thrombosis, restenosis within the stent, bleeding complications when antiplatelets are used after stenting, and higher cost. The combination of aspirin and P2Y12 antagonists is effective in preventing coronary stent thrombosis and the duration of therapy depends on whether bare metal stents (BMS) or drug-eluting stents (DES) are used. Duration of dual antiplatelet therapy can be as short as 4 weeks for BMS, but 6 to 12 months of therapy is generally required for DES. This difference in duration is due to the lack of endothelium proliferation in DES initially. New drug-eluting stents with thin struts releasing Limus-family analogs from durable polymers have lowered the risk of stent thrombosis compared with early-generation stents releasing sirolimus or paclitaxel. Current evidence supports the use of drug-eluting stents in most clinical settings without safety concerns (unless there are contraindications to use of dual antiplatelet therapy).

PEARLS & CONSIDERATIONS

COMMENTS

- Although nitrate responsiveness is usually an integral part of a diagnostic strategy for SIHD, recent reports question its value and conclude that in a general population admitted for chest pain, relief of pain after nitroglycerin treatment does not predict active CAD and should not be used to guide diagnosis in the acute care setting.
- CABG is associated with higher long-term survival rates and lower rates of repeat revascularization than PCI and stenting; however, patients often prefer stenting because it is less invasive, involves a shorter hospital stay, and has a lower in-hospital mortality rate.

Angioedema PTG ALG

BASIC INFORMATION

DEFINITION

- The mucocutaneous swelling caused by the release of vasoactive mediators is called urticaria and angioedema.
- Urticaria causes edema of the superficial dermis.
- Angioedema involves the deep layers of the dermis and the subcutaneous tissue.

SYNONYMS

Angioneurotic edema
HAE (hereditary angioedema)

ICD-10CM CODES
T78.3 Angioedema
D84.1 Angioedema, hereditary

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 100 to 3000/100,000 persons (for urticaria and angioedema)
LIFETIME PREVALENCE: Approximately 20% of the population experiences urticaria and/or angioedema at some time during life. The prevalence of hereditary angioedema is 1 case per 50,000 persons.
DEMOGRAPHICS:

- Race: Slightly more common among African Americans.
- Sex: More occurrences in women than men.
- Angioedema commonly occurs after adolescence in the third decade of life.
- Angioedema can occur together with urticaria (40%) or alone (20%); the remaining 40% have urticaria alone.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Angioedema may be acute or chronic
  1. Acute angioedema is defined as symptoms lasting 6 wk
  2. Chronic angioedema is defined as symptoms lasting >6 wk
- Urticaria is commonly known as "hives" and is:
  1. Pruritic
  2. Palpable and well demarcated
  3. Erythematous
  4. Millimeters to centimeters in size
  5. Multiple in number
  6. Fades within 12 to 24 hr
  7. Reappears at other sites
- Angioedema is characterized by the following:
  1. Nonpruritic
  2. Burning
  3. Not well demarcated
  4. Involves eyelids, lips (Fig. 1), tongue, and extremities
  5. Can involve the upper airway, causing respiratory distress
  6. Can involve the gastrointestinal tract, leading to cyclic abdominal pain, nausea, vomiting, and diarrhea
  7. Resolves slowly

ETIOLOGY

- Angioedema, with or without urticaria, is classified as acquired (allergic or idiopathic) or hereditary.
- Angioedema is primarily caused by mast cell activation and degranulation with release of vasoactive mediators (e.g., histamine, serotonin, bradykinins), resulting in postcapillary venule inflammation, vascular leakage, and edema in the deep layers of the dermis and subcutaneous tissue.
- Pathologically, angioedema has both immunologic- and nonimmunologic-mediated mechanisms (Fig. 2).
  1. Immunoglobulin E–mediated angioedema may result from antigen exposure (e.g., foods [milk, eggs, peanuts, shellfish, tomatoes, chocolate, sulfites] or drugs [penicillin, aspirin, nonsteroidal antiinflammatory drugs, phenytoin, sulfonamides, recombinant tissue plasminogen activator]).
  2. Complement-mediated angioedema involving immune complex mechanisms can also lead to mast cell activation that manifests as serum sickness.
  3. Hereditary angioedema is an autosomal-dominant disease caused by a deficiency of or mutation in C1 esterase inhibitor (C1-INH). C1-INH is a protease inhibitor normally present in high concentrations in the plasma. C1-INH serves many functions, one of which is to inhibit plasma kallikrein, a protease that cleaves kininogen and releases bradykinin. Deficient C1-INH activity results in excess concentration of kininogen and the subsequent release of kinin mediators.
  4. Acquired angioedema is usually associated with other diseases, most commonly B-cell lymphoproliferative disorders, but may also result from the formation of autoantibodies directed against C1 inhibitor protein.
  5. Other causes of angioedema include infection (e.g., herpes simplex, hepatitis B, Coxsackie A and B, *Streptococcus, Candida, Ascaris,* and *Strongyloides*), insect bites and stings, stress, physical factors (e.g., cold, exercise, pressure, and vibration), connective tissue diseases (e.g., systemic lupus erythematosus, Henoch-Schönlein purpura), and idiopathic causes. Angiotensin-converting enzyme (ACE) inhibitors can increase kinin activity and lead to angioedema.

FIG. 1 Angioedema. The swelling is deeper than wheals and may affect mucosal surfaces. Note the swelling of the lips and periorbital region and the lack of erythema. (From Bolognia J et al: *Dermatology,* ed 4, London, 2018, Elsevier Limited.)

DIAGNOSIS

A detailed history and physical examination usually establish the diagnosis of angioedema. Extensive laboratory testing is of limited value.

DIFFERENTIAL DIAGNOSIS

- Cellulitis
- Arthropod bite
- Hypothyroidism
- Contact dermatitis
- Atopic dermatitis
- Mastocytosis
- Granulomatous cheilitis
- Bullous pemphigoid
- Urticaria pigmentosa
- Anaphylaxis
- Erythema multiforme
- Epiglottitis
- Peritonsillar abscess

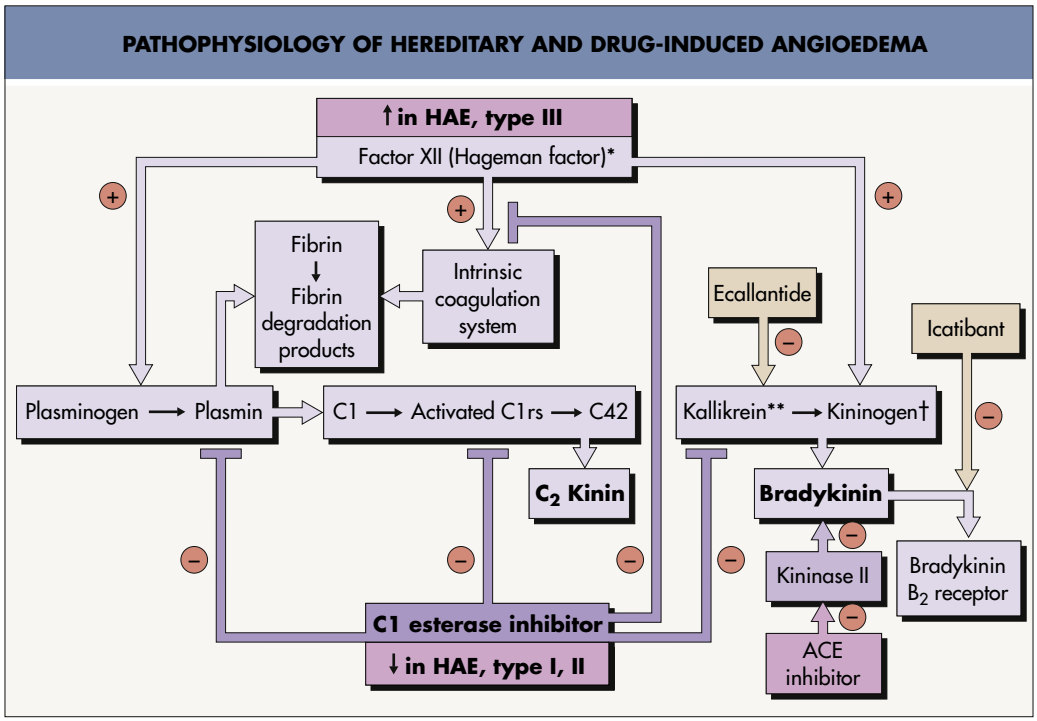

FIG. 2 Pathophysiology of hereditary and drug-induced angioedema. Angiotensin-converting enzyme *(ACE)* inhibitor-induced urticaria is believed to result from the inhibition of endogenous kininase and a subsequent increase in bradykinin. Icatibant and ecallantide have been approved for the emergency treatment of hereditary angioedema *(HAE)* as alternatives to C1 esterase inhibitor (C1-INH) concentrate (derived from human plasma) or recombinant C1-INH (derived from milk of transgenic rabbits). Icatibant, a decapeptide, is a specific bradykinin B2 receptor antagonist. Ecallantide, a 60-amino acid recombinant protein, selectively inhibits kallikrein. Off label, icatibant has been used to treat ACE inhibitor-induced angioedema. Two forms of C1-INH, one of which is administered intravenously and the other subcutaneously, are approved for prevention of attacks. At the time of writing, twice-monthly administration of lanadelumab, a human monoclonal antibody that inhibits plasma kallikrein, is under investigation for prevention of attacks. *The active form of factor XII (Hageman factor) is XIIa. **Kallikrein is formed from prekallikrein. †High-molecular-weight. (From Bolognia J et al: *Dermatology,* ed 4, London, 2018, Elsevier Limited.)

WORKUP

- An extensive workup searching for the cause of angioedema is often unrevealing (90%).
- Workup, including diagnostic blood tests and allergy testing, is performed according to results of the history and physical examination. Fig. 3 illustrates an algorithm for the diagnosis of angioedema.

LABORATORY TESTS

- Complete blood count, erythrocyte sedimentation rate, and urinalysis are sometimes helpful as part of the initial evaluation.
- Stools for ova and parasites.
- Serology testing.
- C4 levels are usually reduced in acquired and hereditary angioedema (occurring without urticaria). If C4 levels are low, C1-INH levels and activity should be obtained. There are isolated reports of hereditary angioedema with normal C4 levels but reduced C1-INH levels.
- Skin and radioallergosorbent testing may be done if food allergies are suspected.
- Skin biopsy is usually done in patients with chronic angioedema refractory to corticosteroid treatment.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Eliminate the offending agent
- Avoid triggering factors (e.g., cold, stress)
- Cold compresses to affected areas

ACUTE GENERAL Rx

- Acute life-threatening angioedema involving the larynx is treated with:
  1. Epinephrine 0.3 mg in a solution of 1:1000 given SC
  2. Diphenhydramine 25 to 50 mg IV or IM
  3. Cimetidine 300 mg IV or ranitidine 50 mg IV
  4. Methylprednisolone 125 mg IV
- Mainstay therapy in nonhereditary angioedema is H_1 antihistamines:
  1. Diphenhydramine 25 to 50 mg q6h
  2. Chlorpheniramine 4 mg q6h
  3. Hydroxyzine 10 to 25 mg q6h
  4. Cetirizine 5 to 10 mg qd
  5. Loratadine 10 mg qd
  6. Fexofenadine 60 mg qd
- H_2 antihistamines can be added to H_1 antihistamines:
  1. Ranitidine 150 mg bid
  2. Cimetidine 400 mg bid
  3. Famotidine 20 mg bid
- Tricyclic antidepressants:
  1. Doxepin 25 to 50 mg qd
- Corticosteroids are rarely required for symptomatic relief of acute angioedema
- Antihistamines are probably ineffective in acute hereditary angioedema.
- Purified plasma-derived C1-INH replacement therapy is effective and safe in treating acute attacks of hereditary angioedema caused by C1 inhibitor deficiency. Cost is a limiting factor. Acute attacks can be managed with plasma-derived or recombinant preparations of C1 inhibitor, with ecallantide, a specific plasma kallikrein inhibitor, or with the use of the B2 bradykinin-receptor antagonist icatibant

CHRONIC Rx

- Chronic angioedema is treated as described under "Acute General Rx." Corticosteroids are used more often in chronic nonhereditary angioedema.
- Prednisone 1 mg/kg/day for 5 days and then tapered over a period of weeks.

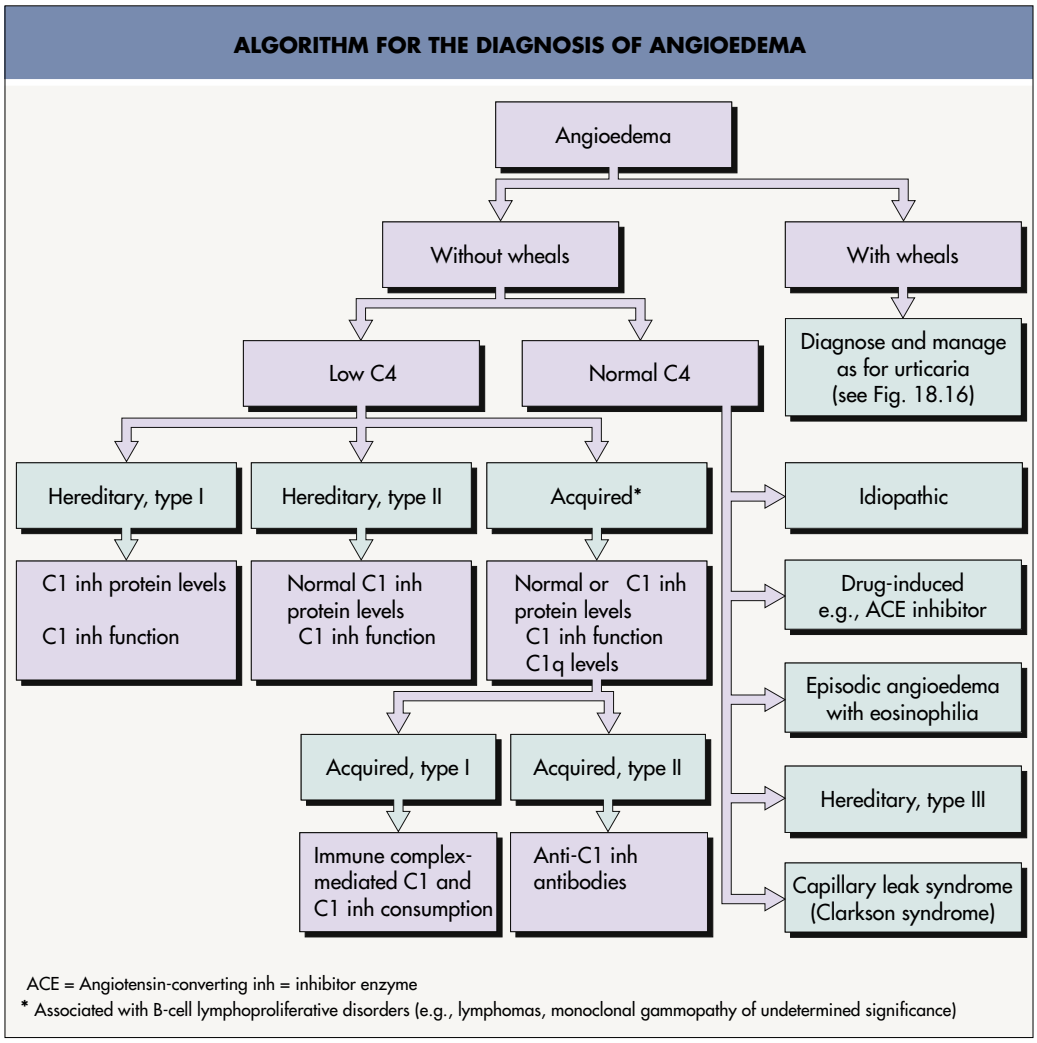

FIG. 3 Algorithm for the diagnosis of angioedema. Episodic angioedema with hypereosinophilia, along with weight gain and fever, is known as Gleich syndrome. (From Bolognia J et al: *Dermatology,* ed 4, London, 2018, Elsevier Limited.)

- Androgens (danazol, stanozolol, oxandrolone, methyltestosterone) and antifibrinolytic agents can be used for the treatment of chronic hereditary angioedema, which does not respond to antihistamines or corticosteroids but these agents are associated with many adverse effects.
- Long-term prophylaxis with intravenous plasma-derived C1 inhibitors (Cinryze, Berinert) are safe and effective and may be used in patients who have frequent or severe attacks. Cost can be a limiting factor. A twice-weekly subcutaneous formulation (Haegarda/CSL830, CSL Behring) is approved by the FDA to treat type I and type II hereditary angioedema. Icatibant is a bradykinin-receptor antagonist effective in hereditary angioedema. Lanadelumab is a kallikrein inhibitor shown in preliminary studies to reduce attack frequency, although it is not yet FDA approved.

DISPOSITION

- Antihistamines achieve symptomatic relief in more than 80% of patients with nonhereditary acute angioedema.
- In chronic nonhereditary angioedema, corticosteroids are given in addition to antihistamines.
- A small percentage of people will have recurrence of symptoms after steroid treatment.
- Chronic angioedema can last for months and even yrs.

REFERRAL

Consultation with dermatologist and allergist is recommended in patients with chronic angioedema, hereditary angioedema, and recurring angioedema.

PEARLS & CONSIDERATIONS

ACE inhibitors can cause angioedema up to many months after initiation. There are multiple case reports and case series of angiotensin receptor blocker (ARB)–induced angioedema, although the risk is substantially less than that of ACE inhibitors. (Incidence rates per 1000 person-yr are 4.38 cases for ACE inhibitors, 1.66 cases for ARBs.) The incidence rate is also very high for the direct renin inhibitor aliskiren (4.67).

COMMENTS

- Identifying a cause for angioedema in patients is often difficult and met with frustration.
- Chronic angioedema, unlike acute angioedema, is rarely caused by an allergic reaction.

Angular Cheilitis

BASIC INFORMATION

DEFINITION

Angular cheilitis refers to inflammation of one, or both, of the corners of the mouth resulting in erythema, fissuring, and exudate of the mouth angle (Fig. E1). Most commonly, it represents an infectious etiology, as an opportunistic fungal or bacterial pathogen, and leads to a spectrum of varying severities.

SYNONYMS

Angular cheilosis
Rhagades
Commissural cheilitis
Perleche
Angular stomatitis

ICD-10CM CODES	
K13.0	Diseases of lips
B37.83	Candidal cheilitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Unknown
PEAK INCIDENCE: Advanced age
PREVALENCE: Suspected of causing 0.5% to 5% of lip infections in adults
PREDOMINANT SEX AND AGE: This form of lip inflammation has a predilection for the elderly, seen with denture use as an example.
GENETICS: No identified correlation
RISK FACTORS: These include dry mouth, nutritional deficiencies (B vitamins, iron), immunosuppression, or chronic irritation as with lip licking, drooling, oral hardware, or dentures.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The majority of cases of this lip condition involve both sides of the mouth, which initially involves erythema and swelling (Fig. E2). Over time, the erythema and subsequent linear fissures, or rhagades, may become cracked or ulcerated. Skin thickening is common during the progression of inflammation. It is important to note that this progression may involve strictly the mucosa of the lips or may propagate to the facial dermis, crossing the vermillion border.

ETIOLOGY

Microorganisms commonly represent underlying infectious causes. These include *Candida* species*, Staphylococcal aureus,* beta-hemolytic *Streptococcus* species, or polymicrobial findings. Another common cause of this condition includes direct irritation of saliva on the corners of the mouth with overclosure of the lower jaw, as evident in edentulous individuals and those who wear dentures. Nearly any condition that leads to chronic irritation or moisture settling in the corners of the mouth, including lip licking, drooling, or habits of oral fixation, may lead to this state. Nutritional deficiencies, specifically of iron, B vitamins, and zinc, are also associated with angular cheilitis. Varying levels of immunosuppression, as seen in diabetes mellitus, HIV, and so on, predispose to subacute infection as well. Patients on medications leading to xerostomia or hypersalivation can develop bilateral involvement.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Oral candidiasis or oral-associated angular cheilitis; *S. aureus* infection or impetigo; contact dermatitis; angular herpes simplex

WORKUP

Primarily clinical in nature, taking into consideration full details of the patient's medical history and medications

LABORATORY TESTS

If applicable, bacterial and fungal cultures may be beneficial to detect probable infectious component with routine lab testing, including CBC, HIV, BMP, iron, folate, and vitamin B_{12}, to be performed as well.

IMAGING STUDIES

None needed

TREATMENT

The hallmark of treatment used in this condition revolves around proper identification and understanding of the etiology of the inflammation. With the highest prevalence of this condition seen in those with dentures, proper oral fit and dental hygiene are of the utmost importance.

Certainly, good oral hygiene also includes smoking and tobacco use cessation. Topical antifungal use is at the cornerstone of treatment (details follow). Proper identification may include the presence of *S. aureus, Streptococcus* species, and other pathogens, which will need focused treatment. Treatment-refractory cheilitis may require additional workup to identify possible systemic etiology.

NONPHARMACOLOGIC THERAPY

Dental hygiene, specifically, with a focus on proper cleaning of dentures, plays a pivotal role in prevention. Alcohol or bleach-based solutions are commonly available OTC. If significant lag is noted in the corners of the mouth, surgery and collagen injections have been successful. Petrolatum jelly has been used for preventive measures as well.

ACUTE GENERAL Rx

With the underlying pathology involving inflammation, topical corticosteroid creams are commonly used. If *S. aureus* has been implicated, topical mupirocin or fusidic acid has a role. Clotrimazole or ketoconazole can be used for combating *Candida albicans*, implicated in >50% of cases.

FIG. E1 Perlèche (angular cheilitis). Erythema, fissuring, and exudate of the mouth angle. (From Paller AS, Mancini, AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

FIG. E2 Angular cheilitis. (From Swartz MH: *Textbook of physical diagnosis, history and examination,* ed 7, Philadelphia, 2014, Saunders.)

CHRONIC Rx

Pending laboratory workup and identification of a nutritional deficiency, iron, B vitamins, or folate supplementation will likely lead to reduction. Proper alignment of dentures, involving possible surgical repair and fitment, may be needed.

DISPOSITION

Outpatient workup and assessment

REFERRAL

Dermatology assessment may be needed in refractory cases of angular cheilitis.

PEARLS & CONSIDERATIONS

COMMENTS

Identification of etiology is of utmost importance for further workup.

PREVENTION

See previously.

AUTHOR: **Fred F. Ferri, M.D.**

BASIC INFORMATION

DEFINITION

Ankle fractures typically involve the lateral, medial, and/or posterior malleolus of the ankle. These structures can be affected in isolation or as part of a combined injury pattern. Ligamentous and syndesmotic injuries are commonly seen in addition to bony injuries. Ankle fractures can occur as a result of high-energy trauma or simple ground-level falls.

CLASSIFICATION

The Danis-Weber (Figs. E1, E2, E3) and Lauge-Hansen classifications of ankle fractures are described in Table E1.

ICD-10CM CODES

S82.63XA	Displaced fracture of lateral malleolus of unspecified fibula, initial encounter for closed fracture
S82.53XA	Displaced fracture of medial malleolus of unspecified tibia, initial encounter for closed fracture
S82.841(A-S)	Displaced bimalleolar fracture of right lower leg
S82.842(A-S)	Displaced bimalleolar fracture of left lower leg
S82.851(A-S)	Displaced trimalleolar fracture of right lower leg
S82.852(A-S)	Displaced trimalleolar fracture of left lower leg
S82.899	Other fracture of unspecified lower leg, initial encounter for closed fracture

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Deformity usually depends on extent of displacement (i.e., dislocation)

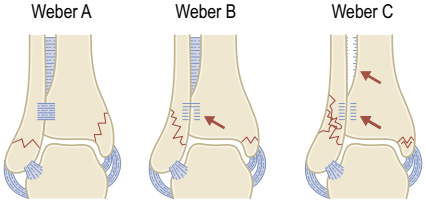

FIG. E1 Diagram showing the Weber classification for ankle fractures. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, Philadelphia, 2019, Elsevier.)

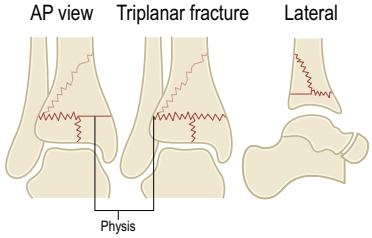

FIG. E2 Diagram showing the fracture configuration in a triplanar fracture. *AP,* Anteroposterior. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.)

- Pain, tenderness, and ecchymosis at the site of injury
- Evaluation of neurovascular status before and after reduction/splinting

ETIOLOGY

- The ankle depends on its ligamentous and bony support for stability. The joint, or *mortise*, is an inverted U with the dome of the talus fitting into the medial and lateral malleoli. The posterior margin of the tibia is often called the *posterior malleolus.*
- The most common ankle fractures are the result of eversion or lateral rotation forces on the talus (in contrast with common sprains, which are usually caused by inversion).

DIAGNOSIS

The diagnosis is usually established on the basis of the nature of the injury, the presence of typical findings of bony tenderness with swelling, and abnormal imaging studies.

DIFFERENTIAL DIAGNOSIS

- Ankle sprain
- Fracture of hindfoot or metatarsal
- Osteochondral lesion
- Tendon tear or rupture
- Syndesmotic injury

IMAGING STUDIES

Standard AP and lateral views (Fig. E4) accompanied by a mortise view taken with 10 degrees of internal rotation. The last view is taken to properly visualize the mortise. Fig. E5 illustrates the Ottawa ankle rules for ankle or midfoot fracture.

TREATMENT

All fractures: Elevation, compression, and ice to control swelling for 48 to 72 hr; immobilization in splint or fracture boot with ambulatory aid as needed.

ACUTE GENERAL Rx

- Clinical and radiographic assessment of the status of the ankle mortise and stability of the injury is indicated to determine treatment.
- There is potential for instability if both sides of the ankle joint are significantly injured (e.g., fracture of the lateral malleolus with medial deltoid ligament injury).

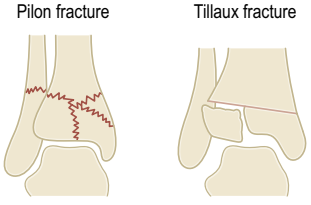

FIG. E3 Diagram showing the fracture configuration in a Pilon fracture and Tillaux fracture. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.)

- Deviation of the position of the talus in the mortise can lead to traumatic arthritis.
- If there is no widening of the ankle mortise on stress or weight-bearing radiographs, many isolated lateral malleolus injuries can be safely treated with simple splinting or bracing without reduction:
  1. Isolated fractures of the lateral malleolus without evidence of medial clear space widening on stress or weight-bearing radiographs:
     a. May be treated with a controlled ankle movement (CAM) boot if no medial injury is present.
     b. Weight bearing as tolerated.
     c. From 4 to 6 wk of immobilization is usually sufficient.
     d. If signs of instability are already present at initial examination (widening of the medial clear space), referral for possible operative intervention is indicated.
- Lateral malleolus fractures with medial clear space widening, bimalleolar ankle fractures, and trimalleolar fractures:
  1. These injuries typically necessitate reduction and splinting if displaced or dislocated followed by orthopedic surgery follow-up and possible operative intervention.
  2. Operative intervention typically includes reduction and fixation of the fibula with a plate and screws as well as screw fixation of the medial malleolus plus or minus syndesmotic fixation.
  3. These patients are typically kept non–weight-bearing for 6 to 8 wk.

CHRONIC Rx

- Early range of motion is encouraged through a home exercise program.
- Protection from reinjury is appropriate for 4 to 6 wk after cast or brace removal.
- A temporary increase in lower extremity swelling that frequently occurs after short leg cast removal may benefit from the use of support hose and continued elevation.

DISPOSITION

Significant factors involved in the development of traumatic arthritis:

- Extent of joint trauma at the time of injury
- Eventual position of the talus in the mortise

REFERRAL

Orthopedic consultation for:

- Unstable or dislocated ankle joint
- Widened ankle mortise
- Bimalleolar or trimalleolar fracture pattern
- Posterior malleolus fracture over 20% of joint with incongruity
- Marked displacement of fracture fragment
- Open fracture

Box E1 summarizes ankle fractures for which orthopedic consultation in the emergency department is recommended.

TABLE E1 Classifications and Treatment of Ankle Fractures

	Normal	Abnormal
Medial clear space—distance between lateral border of medial malleolus and medial border of talus	<4 mm	>4 mm = lateral talar shift and concern for **instability**
Tibiofibular clear space—distance between medial wall of fibula and tibial incisura 1 cm above the ankle joint	<6 mm on AP and mortise views	>6 mm = concern for **syndesmotic disruption (instability)**
Tibiofibular overlap—maximum amount of fibular overlap of tibia	>6 mm on AP view >1 mm on mortise view	<6 mm = concern for **instability** <1 mm on mortise = concern for **instability**
Classification:		
1. **Danis-Weber**—based on location of fibula fracture A. Below the level of the syndesmosis B. At the level of the syndesmosis C. Above the level of the syndesmosis	1. **Lauge-Hansen**—based on position of foot and deforming force A. Supination external rotation—most common B. Supination adduction C. Pronation external rotation D. Pronation abduction	
Treatment: Decision for operative versus nonoperative treatment relies mostly on stability of fracture pattern		
Stable	**Unstable**	
Isolated lateral malleolar fractions if:	**Lateral malleolus fractures** if:	
No indication of medial ligamentous injury or medial clear space widening on stress examination	Evidence of instability (medial clear space widening) on stress or weight-bearing radiographs	
No fibular shortening	Fibular shortening	
	Bimalleolar or trimalleolar ankle fractures (consider fixation of posterior malleolus if >20% of articular surface involved)	
	Maisonneuve fractures (rotational injury)	

Updated from Parvizi J: *High-yield orthopedics,* Philadelphia, 2010, Saunders.

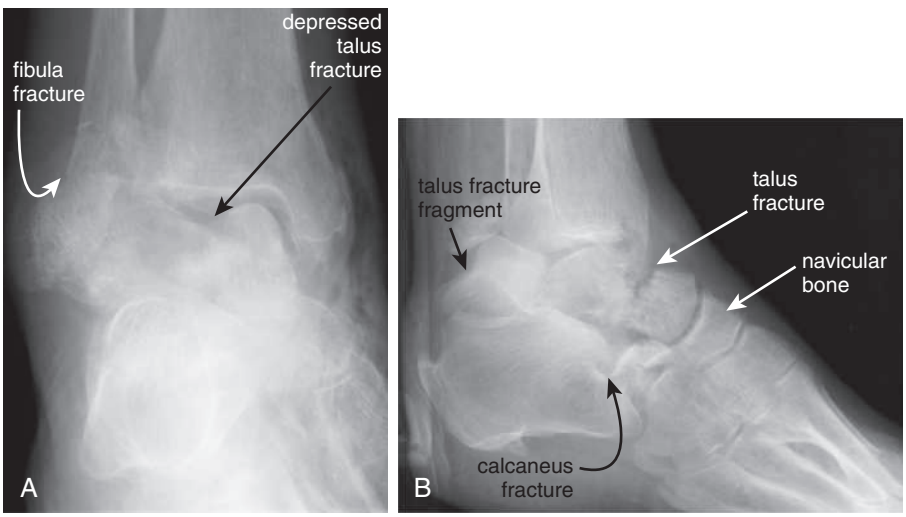

FIG. E4 A, Anteroposterior view. **B,** Lateral view. A depressed talus fracture is visible. In **B,** this fracture is seen to run through the midbody of the talus. **A** also demonstrates a distal fibula fracture, but in **B,** a calcaneal fracture is seen. The patient underwent computed tomography to characterize these fractures further. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.)

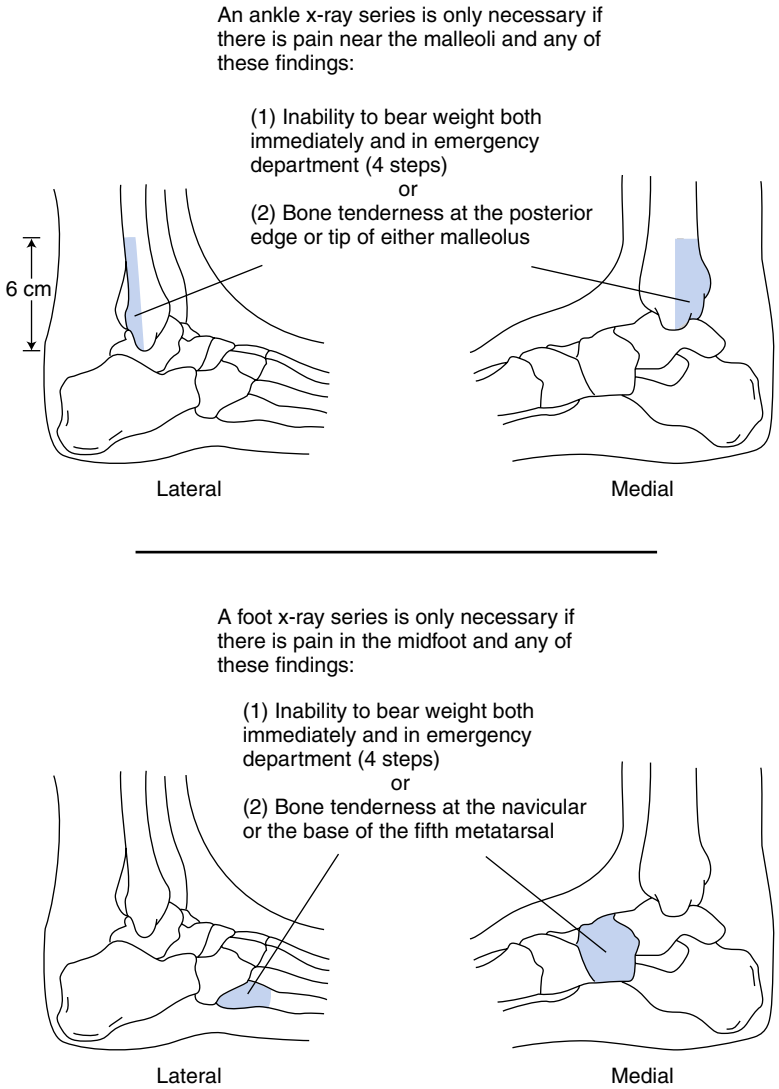

FIG. E5 Ottawa rules for ankle or midfoot fracture. The rule for ankle pain is the top figure; the rule for midfoot pain is the bottom figure. The rule is positive if any indication for radiography is met. "Inability to take four steps" means the patient is unable to transfer weight twice onto each lower limb regardless of limping. Importantly, these rules apply *only* to patients with injury of the ankle or midfoot, and they exclude patients with injury to the body or tuberosities of the calcaneus. (Adapted from Stiell IG et al: A study to develop clinical decision rules for the use of radiography in acute ankle injuries. In McGee S: *Evidence-based physical diagnosis,* ed 4, Philadelphia, 2018, Elsevier.)

BOX E1 Ankle Fractures for Which Orthopedic Consultation in the Emergency Department Is Recommended

- Unimalleolar fractures
- Displaced medial malleolar fracture
- Displaced lateral malleolar fracture
- Lateral malleolar fracture with deltoid ligament rupture
- Lateral malleolar fracture with widened medial clear space or syndesmotic diastasis
- Fibula fracture at or proximal to the tibiotalar joint line
- Displaced posterior malleolar fracture
- Posterior malleolar fracture involving more than 20% of articular surface
- All bimalleolar fractures
- All trimalleolar fractures
- All intraarticular fractures with displacement
- All open fractures

From Marx JA et al: *Rosen's emergency medicine,* ed 8, Philadelphia, 2014, Saunders.

BASIC INFORMATION

DEFINITION

An ankle sprain is an injury to the ligamentous structures that support the ankle joint. Most (85%) involve the lateral ligament complex (Fig. E1). The anterior inferior tibiofibular ligament (AITFL), deltoid ligament, and interosseous membrane may also be injured. A severe form of ankle sprain involves disruption of the ankle syndesmosis, known as a high ankle sprain. Lateral ankle sprains are classically graded I, II, or III in respect to specific ligament involvement and their integrity. Table E1 describes a classification of ankle sprains. The anterior talofibular ligament (ATFL) is the most commonly affected lateral ligament.

ICD-10CM CODES

S93.409A	Sprain of unspecified ligament of unspecified ankle, initial encounter
S93.411A	Sprain of calcaneofibular ligament of right ankle, initial encounter
S93.411D	Sprain of calcaneofibular ligament of right ankle, subsequent encounter
S93.411S	Sprain of calcaneofibular ligament of right ankle, sequela

S93.432S	Sprain of tibiofibular ligament of left ankle, sequela
S93.439A	Sprain of tibiofibular ligament of unspecified ankle, initial encounter
S93.439D	Sprain of tibiofibular ligament of unspecified ankle, subsequent encounter
S93.439S	Sprain of tibiofibular ligament of unspecified ankle, sequela

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: One case/10,000 people each day. Especially prevalent in rigorous sports and training such as for basketball, football, and soccer
PREDOMINANT SEX: Varies according to age and level of physical activity

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Often a history of a "pop."
- Variable amounts of tenderness and hemorrhage (inversion sprains: Tender laterally; syndesmotic injury: Tender anterior leg about middle third of the leg).
- Anterior talofibular ligament (ATFL) evaluation: Anterior drawer test. With the patient in the sitting position and knee flexed allow the ankle to plantar-flex slightly and apply an anterolateral rotatory force to the heel. Positive if abnormal increase in forward movement of the talus on the tibia (Fig. E2).
- Syndesmotic evaluation: Manual squeeze test. (Compress the tibia and fibula toward each other at the middle third of the anterior leg. Splaying and pain are indicative of injury.)
- Talar tilt test or inversion stress test (Fig. E3).
- Severe tenderness to direct palpation of ligamentous structure.

ETIOLOGY

- Lateral injuries usually result from inversion and plantar flexion injuries.
- Eversion and rotational forces may injure the deltoid ligament, AITFL, or the interosseous membrane.
- Balance deficits/diminished proprioception.
- Evertor muscle weakness.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Fracture of the ankle or foot, particularly involving the distal fibular physis in the immature patient (e.g., calcaneal fracture, lateral and/or medial malleoli fracture, talar dome fracture, Lisfranc injury)
- Avulsion fracture of the fifth metatarsal base
- Achilles tendon rupture
- Peroneal tendon rupture

WORKUP

- History and clinical examination are usually sufficient to establish the diagnosis.
- Plain radiographs are not always needed.

IMAGING STUDIES

Radiographic evaluation (Fig. E4 and Fig. E5): According to the Ottawa ankle rules (Table E2), radiography is indicated if there is pain in the malleolar or midfoot zone and either bone

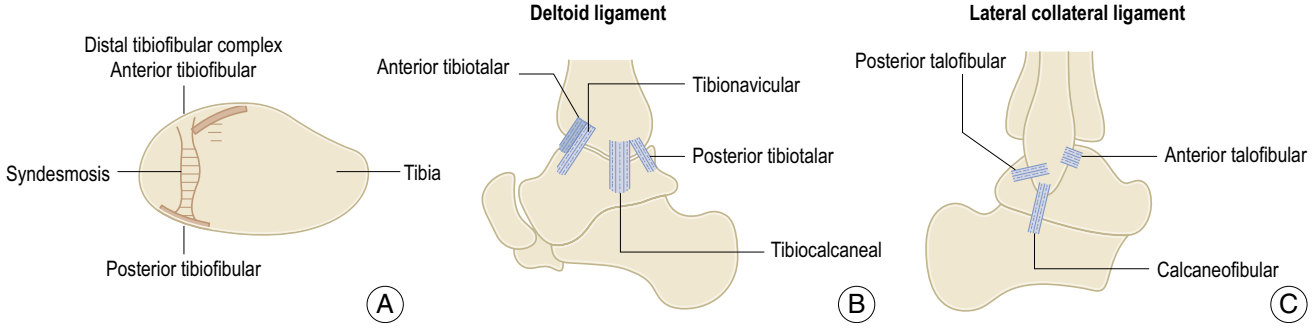

FIG. E1 A, Diagram showing the anatomy of the ligaments around the ankle when viewed from above. **B** and **C,** Diagrams showing the components of the deltoid and lateral collateral ligaments of the ankle. The distal tibiofibular complex (including the anterior and posterior tibiofibular ligaments and syndesmosis) is an important ankle stabilizer. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.)

TABLE E1 Classifications of Ankle Sprains

Grade	Extent of Injury	Physical Findings	Treatments
I	Sprain of ATFL (mid-stretching of lateral ligament complex)	Mild swelling and tenderness; no joint instability	Weight bear as tolerated; free ROM exercises
II	ATFL tear CFL sprain	Moderate swelling and tenderness; laxity with positive anterior drawer test	Immobilization (air splint, CAM boot), physical therapy
III	ATFL tear CFL tear	Severe swelling and tenderness; instability with anterior drawer test and talar tilt; inability to bear weight	Immobilization, physical therapy (longer duration than grade II); surgery if symptoms unresolved

ATFL, Anterior talofibular ligament; *CAM,* controlled ankle movement; *CFL,* calcaneofibular ligament; *ROM,* range of motion.

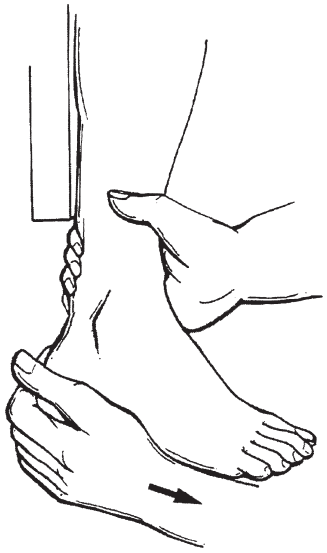

FIG. E2 Anterior drawer test of the ankle (tests the integrity of the anterior talofibular ligament). (From Brinker MR, Miller MD: *Fundamentals of orthopaedics,* Philadelphia, 1999, WB Saunders.)

FIG. E3 Talar tilt test (inversion stress) of the ankle (tests the integrity of the anterior talofibular ligament and the calcaneofibular ligament). (From Brinker MR, Miller MD: *Fundamentals of orthopaedics,* Philadelphia, 1999, WB Saunders.)

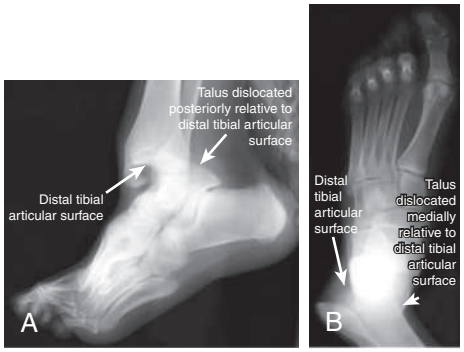

FIG. E4 Tibiotalar dislocation. This 17-yr-old male landed on his left ankle after dunking a basketball, sustaining a deformity. His tibiotalar joint is dislocated, with the talus dislocated posteriorly (visible on the lateral view, **A)** and medially (visible on the anterior-posterior view, **B)**. No fractures are present in this case, although fractures are commonly associated with this injury because of the amount of force required to dislocate the ankle. This was an open injury, and the patient underwent exploration, irrigation, and debridement with primary closure. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, WB Saunders.)

tenderness over an area of potential fracture or an inability to bear weight immediately after the injury and in the physician's office. These rules can reduce radiographic evaluation by 30% to 40%. Pearls: Palpate entire distal 6 cm of the fibula and tibia; do not use rule if the patient is younger than 18 yr of age.

Initial imaging should include weight-bearing ankle series (AP, lateral, mortise). Consider manual or gravity external rotation stress view or varus stress view to assess stability.

Rx TREATMENT

ACUTE GENERAL Rx

- The first line of treatment is described by the mnemonic *PRICE:*
  1. ***P***rotection (CAM boot, etc.)
  2. ***R***est
  3. ***I***ce (3 to 7 days)
  4. ***C***ompression
  5. ***E***levation
- Pain control with NSAIDs, acetaminophen, mild opioids.
- In 48 hours, early controlled motion in a functional ankle brace.
- Compression, support, and bracing is best achieved with an Air-Stirrup brace combined with an elastic compression wrap, or lace-up support alone (functional bracing for active patients).
- In 4 to 5 days, exercise against resistance added.
- Short period of immobilization (up to 10 days) in a below-knee cast or Aircast may shorten the recovery period.
- Physical therapy may be indicated to improve proprioception, strengthen the soft tissue structures about the ankle (ligaments, peroneal tendons), and restore ROM.
- Kinesiotaping.
- Surgery is typically recommended for grade III sprains, which consist of a complete torn ligament and significant ligament laxity/instability in young, healthy, athletic patients.
- If there is syndesmotic or deltoid ligament involvement, surgery is also the primary treatment of choice in athletes.

CHRONIC Rx

- Lateral heel and sole wedge to prevent inversion
- Protective taping or bracing during vigorous activities (Fig. E6)
- Strengthening exercises
- Protective bracing or taping indicated for 6 mo in patients with symptomatic grade II and III injuries

DISPOSITION

- Lateral sprains of any severity may cause lingering symptoms for weeks and months.
  1. Some syndesmotic sprains take even longer to heal.
  2. Heterotopic ossification may even develop in the interosseous membrane, but

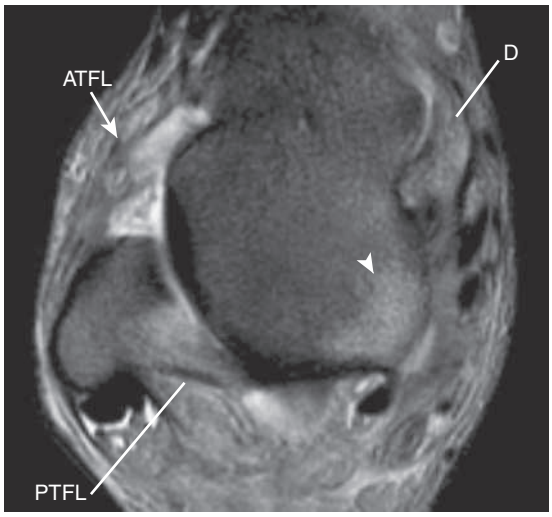

FIG. E5 Acute lateral ankle sprain with multiple ligamentous injuries. Axial fat-suppressed, T2-weighted MR image shows a tear of the anterior talofibular *(ATFL)* ligament *(arrow)*. Other ligamentous injuries include sprain to both the posterior talofibular *(PTFL)* and the deltoid *(D)* ligaments, characterized by loss of normal striation and increased signal on T2-weighted images in these ligaments. Bone bruise of the medial talar dome *(arrowhead)* is present. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2014, WB Saunders.)

TABLE E2 Ottawa Ankle Rules

Accepted Indications: Ankle Radiographs	Accepted Indications: Midfoot Radiographs
Point tenderness about the inferior or posterior aspect of either malleolus (to include the distal 6 cm of the lateral malleolus)	Point tenderness about the navicular or the base of the fifth metatarsal
Inability to bear weight at the time of injury or clinical evaluation (four independent steps)	Inability to bear weight at the time of injury or clinical evaluation (four independent steps)

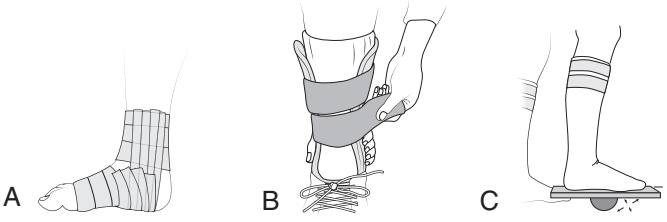

FIG. E6 A, The most effective method of supporting most acute ankle sprains is by using an ACE wrap (BD, Franklin Lakes, NJ) reinforced with 1-inch medial and lateral tape strips. The anterior and posterior aspects of the ankle are left free to allow the patient to flex and extend the ankle. The patient is encouraged to bear weight with crutches. **B,** Diagram of an air splint. Straps are adjusted to heel size, the lower straps are wrapped about the ankle, and the side extensions are centered. The splint is then pressurized, and straps adjusted until comfortable support and pressure are attained. **C,** As the ankle pain subsides, about the third to fifth day, balancing exercises can begin to allow the patient to regain ankle proprioception and avoid recurrent instability problems. (From Jardon OM, Mathews MS: Orthopedics. In Rakel RE [ed]: *Textbook of family practice,* ed 5, Philadelphia, 1995, WB Saunders.)

long-term results do not seem to be affected by such ossification.
- Continuing lateral symptoms may require surgical reconstruction, although late traumatic arthritis or long-term instability is rare regardless of treatment.
- Approximately 15% to 20% of patients require surgical intervention after continued lateral ankle instability after 6 to 8 mo of rigorous physical rehabilitation.

REFERRAL

Orthopedic consultation for patients who do not respond to conservative treatment. Most ankle sprains resolve in 2 to 6 wk.

PEARLS & CONSIDERATIONS

COMMENTS

If healing seems delayed (more than 6 wk), the following conditions should be considered:
- Talar dome fracture
- Reflex sympathetic dystrophy
- Chronic tendinitis
- Peroneal tendon subluxation
- Other occult fracture
- Peroneal weakness (poor rehabilitation)
- A "high" (syndesmotic) sprain

Repeat plain radiographs, bone scan, or MRI may be indicated.

BASIC INFORMATION

DEFINITION

Ankylosing spondylitis (AS) is a type of inflammatory arthritis involving the sacroiliac joints and axial skeleton characterized by ankylosis and enthesitis (inflammation at tendon insertions). It is one of a family of overlapping syndromes called seronegative spondyloarthropathies (SpA) that includes reactive arthritis (formerly Reiter syndrome), psoriatic spondylitis, and enteropathic arthritis.

SYNONYM

Marie-Strümpell disease

ICD-10CM CODES

M45.9	Ankylosing spondylitis of unspecified sites in spine
M08.1	Juvenile ankylosing spondylitis
M45.0	Ankylosing spondylitis of multiple sites in spine
M45.1	Ankylosing spondylitis of occipito-atlanto-axial region
M45.2	Ankylosing spondylitis of cervical region
M45.3	Ankylosing spondylitis of cervicothoracic region
M45.4	Ankylosing spondylitis of thoracic region
M45.5	Ankylosing spondylitis of thoracolumbar region
M45.6	Ankylosing spondylitis lumbar region
M45.7	Ankylosing spondylitis of lumbosacral region
M45.8	Ankylosing spondylitis sacral and sacrococcygeal region

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Between 0.1% and 1% of the population. Varies with prevalence of HLA-B27 and ethnicity. Much higher in those with positive family history of spondyloarthropathy.
PREDOMINANT AGE AT ONSET: 15 to 35 yr, usually symptoms present before age 45
PREDOMINANT SEX: Male:female ratio 2 to 3:1

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Prolonged morning back stiffness of insidious onset lasting more than 3 mo
- Bilateral sacroiliac tenderness (sacroiliitis)
- Inflammatory back pain; often improves with exercise and is worse with rest
- Limited lumbar spine motion
- Tenderness at tendon insertion sites, especially the Achilles tendons and plantar fascia
- Loss of chest expansion reflecting rib cage involvement
- Possible to have peripheral joint arthritis, usually involving lower extremity
- In advanced cases the typical posture consists of compensatory hyperextension of neck, fixed flexion of hips, and compensatory flexion of knees (Fig. 1)
- There is an increased incidence of iritis and uveitis (30% to 40% lifetime prevalence)
- Other extraskeletal manifestations include effects on the cardiovascular system (aortic insufficiency, cardiovascular disease) and lungs (pulmonary fibrosis). There is also an increased risk for osteoporosis

ETIOLOGY

Genetic factors, particularly HLA-B27, play an important role in susceptibility to the spondyloarthropathies. Infectious triggers have been implicated in some cases. Tumor necrosis factor is important in the inflammatory response.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diffuse idiopathic skeletal hyperostosis (Forestier disease)

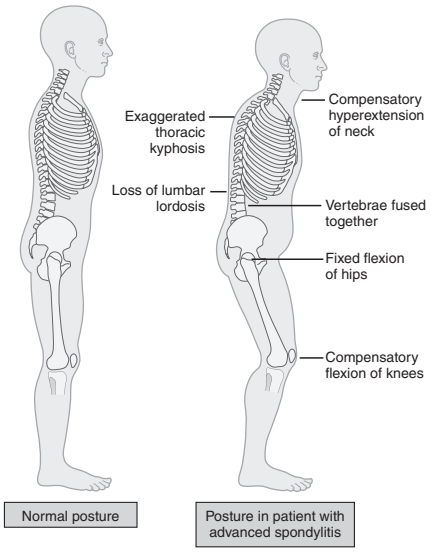

FIG. 1 Ankylosing spondylitis. Typical posture in advanced cases compared with normal posture. (From Ballinger A: *Kumar & Clark's essentials of clinical medicine,* ed 6, Edinburgh, 2012, WB Saunders.)

- Noninflammatory back pain (a clinical algorithm for the evaluation of back pain is described in Section III)
- Table 1 compares ankylosing spondylitis and related disorders

LABORATORY TESTS

- Elevated sedimentation rate, C-reactive protein
- Mild hyperchromic anemia
- Demonstration of inflammatory sacroiliitis by radiography or MRI is diagnostic for most patients, although some patients may meet criteria for "pre-radiographic spondyloarthropathy" based on compelling clinical evaluation
- HLA-B27 antigen is not useful in the evaluation of noninflammatory back pain because it is present in up to 10% of the normal population (varies based on ethnicity)

IMAGING STUDIES

- Classic feature is bilateral sacroiliitis on pelvic radiographs (modified NY criteria).
- Vertebral bodies lose anterior concave shape and become square.
- With progression, calcification of the annulus fibrosus and paravertebral ligaments develops, giving rise to the so-called *bamboo spine.* (Figs. E2 through E6).
- Severe diskovertebral erosions and destruction may occur (Andersson lesion, Fig. 7).
- MRI (Fig. E8) may be useful in detecting early inflammatory lesions and is especially helpful when the history is suggestive but radiographs are equivocal; can see bone marrow edema, fatty metaplasia, sacroiliitis, erosions, shiny corners.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Exercises primarily to maintain flexibility and aerobic activity are important (Fig. E9).
- Postural training:
  1. Patients must be instructed on spinal extension exercises to avoid fusion in a flexed position.

TABLE 1 Comparison of ankylosing spondylitis and related disorders

Feature	Ankylosing spondylitis	Psoriatic arthritis	Reactive arthritis	Enteropathic arthropathy
Gender (male : female)	2-3 : 1	1 : 1	1 : 1	1 : 1
Age of onset	<40 yr	35-55 yr	20-40 yr	Any age
Sacroiliitis or spondylitis (%)	100	~20	~40	<20
Symmetry of sacroiliitis	Symmetrical	Asymmetrical	Asymmetrical	Symmetrical
Peripheral arthritis (%)	~25	95	90	5-20
Distribution	Axial and lower limbs	Variable	Lower limbs	Variable
HLA-B27 positivity (%)	85-95	25-60*	30-70	7-70†
Uveitis	0-40	~20	~50	<15

*60% when spondylitis is present.
†70% when spondylitis is present.

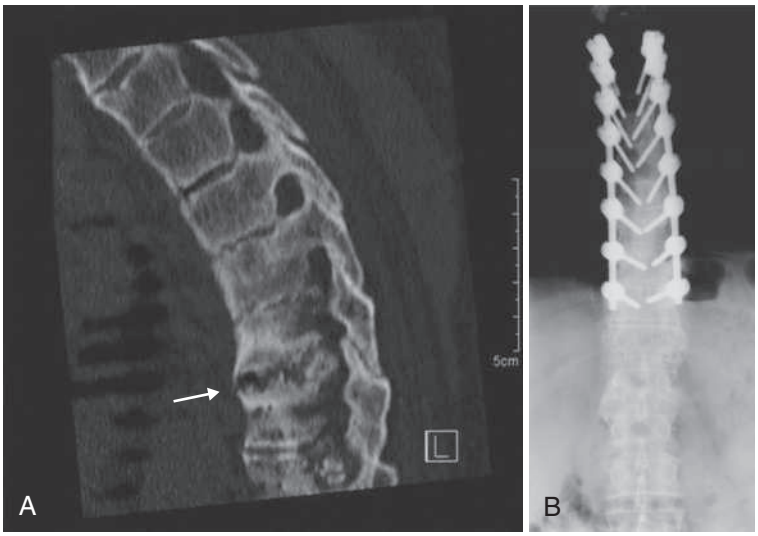

FIG. 7 Severe Andersson lesion (diskovertebral erosions and destruction) (**A,** *arrow*) of the thoracic spine in a patient with ankylosing spondylitis resulting in instability and severe pain, which was treated with a fusion operation **(B).** (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

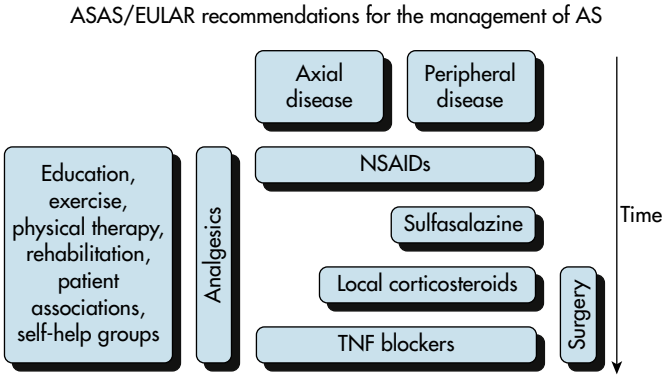

FIG. 10 ASAS/EULAR recommendations for the management of AS. *AS,* Ankylosing spondylitis; *ASAS,* Assessment of SpondyloArthritis international Society; *EULAR,* The European League Against Rheumatism; *NSAIDs,* nonsteroidal anti-inflammatory drugs; *TNF,* tumor necrosis factor. (From van der Linden et al: Ankylosing Spondylitis. In Firestein G et al [eds]: *Kelley & Firestein's textbook of rheumatology,* ed 10, Philadelphia, 2017, Elsevier, Table 75-3, pp. 1271.)

2. Sleeping should be in the supine position on a firm mattress; pillows should not be placed under the head or knees.

PHARMACOLOGIC THERAPY

- NSAIDs: Patients with ankylosing spondylitis should be trialed on full-dose continuous NSAID therapy. There is anecdotal evidence suggesting that indomethacin may be more effective than other NSAIDs, but other NSAIDs are also efficacious and may be better tolerated. One study suggested that continuous NSAID therapy may retard the radiographic progression of ankylosing spondylitis, but data are conflicting.
- Sulfasalazine may be efficacious in patients with peripheral arthritis.
- Numerous controlled trials have shown that tumor necrosis factor (TNF) antagonists such as etanercept, infliximab, and adalimumab are very effective for relieving symptoms of spinal inflammatory arthritis. Anti-TNF therapy should be recommended for patients whose symptoms are not completely controlled with NSAIDs, and it can result in dramatic improvement in symptoms, range of motion of the spine, and quality of life for these patients. There is evidence suggesting that anti-TNF therapy slows the radiographic progression of the disease. Etanercept should generally be avoided if history of uveitis.
- Secukinumab, an anti-interleukin-17A monoclonal antibody, has been approved for treating AS. Ixekizumab, another IL-17A antibody, was also just approved in 2019.
- Fig. 10 shows American College of Rheumatology (ACR)/The European League Against Rheumatism (EULAR) recommendations for management.

DISPOSITION

Most patients have a normal life span but many can suffer significant disability from loss of spinal mobility.

REFERRAL

All patients with seronegative spondyloarthropathy should be referred to a rheumatologist for further evaluation and treatment.

PEARLS & CONSIDERATIONS

A family history of seronegative spondyloarthropathy increases the specificity of testing for HLA-B27. Surgical osteotomy may benefit selected patients with severe spinal deformity. Recent data suggest that men with AS have increased risk of vascular mortality.

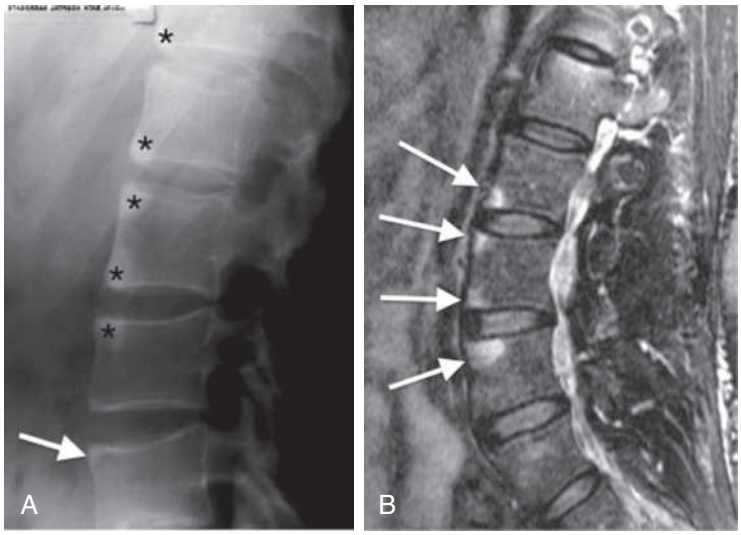

FIG. E2 (A) Ankylosing spondylitis (AS) with sclerosis of the vertebral corners (Romanus lesions). The radiograph shows advanced lesions (*) and an early lesion *(arrow).* **(B)** STIR sagittal MR image of a different AS patient with edema of the vertebral corners *(arrows)* termed *MR Romanus lesions.* (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

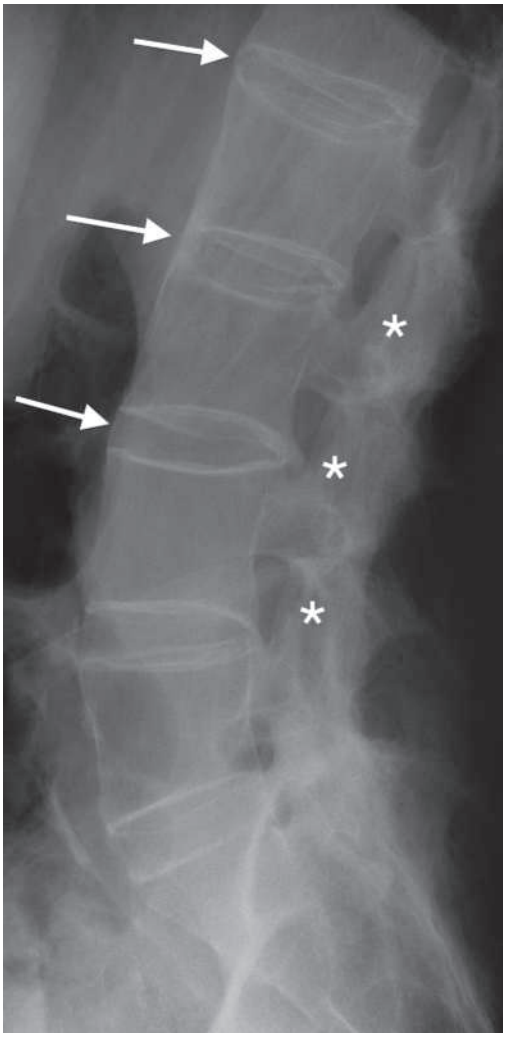

FIG. E3 T1-weighted **(A)** and T2 fat-suppressed **(B)** coronal magnetic resonance images of the sacroiliac joints (SIJ) in ankylosing spondylitis. The T1-weighted image readily demonstrates erosion *(arrows)* in the right SIJ with joint space loss on the left (*), all indicative of damage. Note how poor the T2-weighted image is at demonstrating erosion; however, it shows subchondral edema *(arrows)* more reflective of disease activity. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

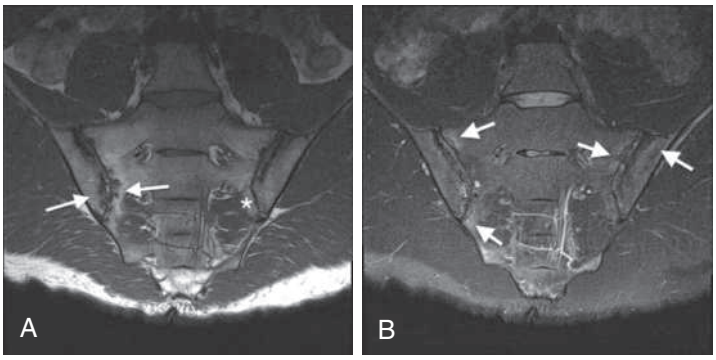

FIG. E4 Ankylosing spondylitis with bamboo spine. Bridging vertical syndesmophytes are seen around the intervertebral discs *(arrows).* Note no facet joint spaces are visualized, indicating fusion of the posterior joints between L3 and S1. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

FIG. E5 Ankylosing spondylitis. Bone ankylosis across the joint cartilage. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

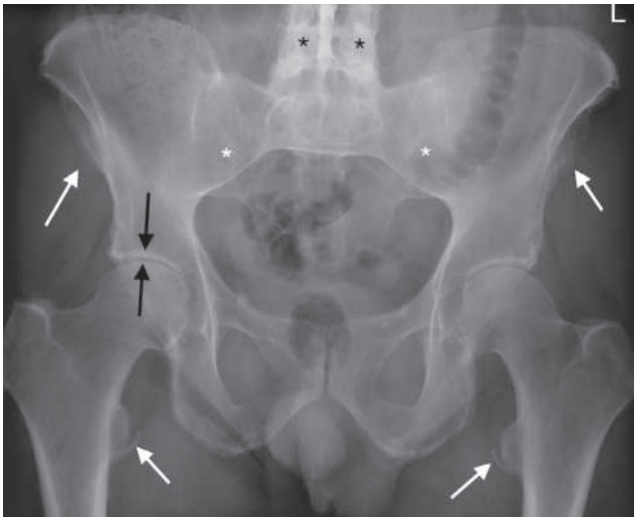

FIG. E6 Patient with ankylosing spondylitis with spinal fusion *(black*)* and SIJ fusion *(white*).* There is hip arthropathy with diffuse loss of joint space *(black arrows)* and flattened configuration of the femoral heads. Widespread entheseal new bone formation is noted around the pelvis *(white arrows).* (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

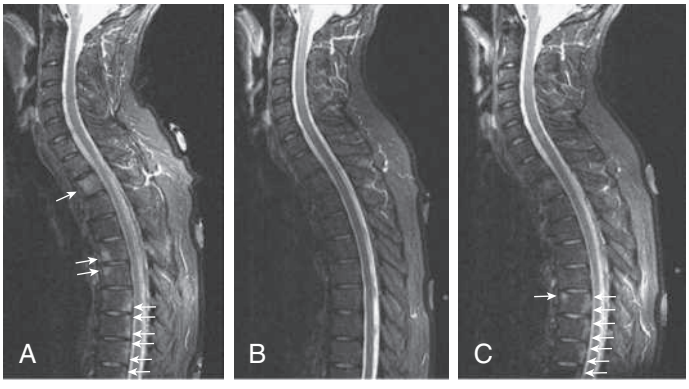

FIG. E8 Spine inflammation in ankylosing spondylitis (magnetic resonance imaging [MRI]). A 43-yr-old man with HLA-B27–positive ankylosing spondylitis with deteriorating symptoms, including inflammatory back pain, had an MRI scan before starting biologic therapy. Baseline sagittal short tau inversion recovery (STIR) MRI **(A)** shows diffuse increased signal (edema) in the T2 vertebral body and multiple foci of corner inflammation anteriorly at T5 and T6, and posteriorly at T7, T8, T9, and T10 *(arrows).* Other images confirmed extensive active inflammation in the spine. The patient responded very well, and after 6 mo of therapy, a repeat STIR MRI **(B)** showed complete resolution of bone marrow inflammation. Subsequently, the patient experienced recurrence of symptoms, and a third MRI **(C)** was performed (2 mo after anti-TNF therapy was stopped). This MRI shows no edema at T5 to T6, a conspicuous new lesion anteriorly at T7, and recurrent inflammation posteriorly in the lower thoracic spine *(arrows).* (From Firestein GS et al: *Kelley's textbook of rheumatology,* ed 9, Philadelphia, 2013, WB Saunders.)

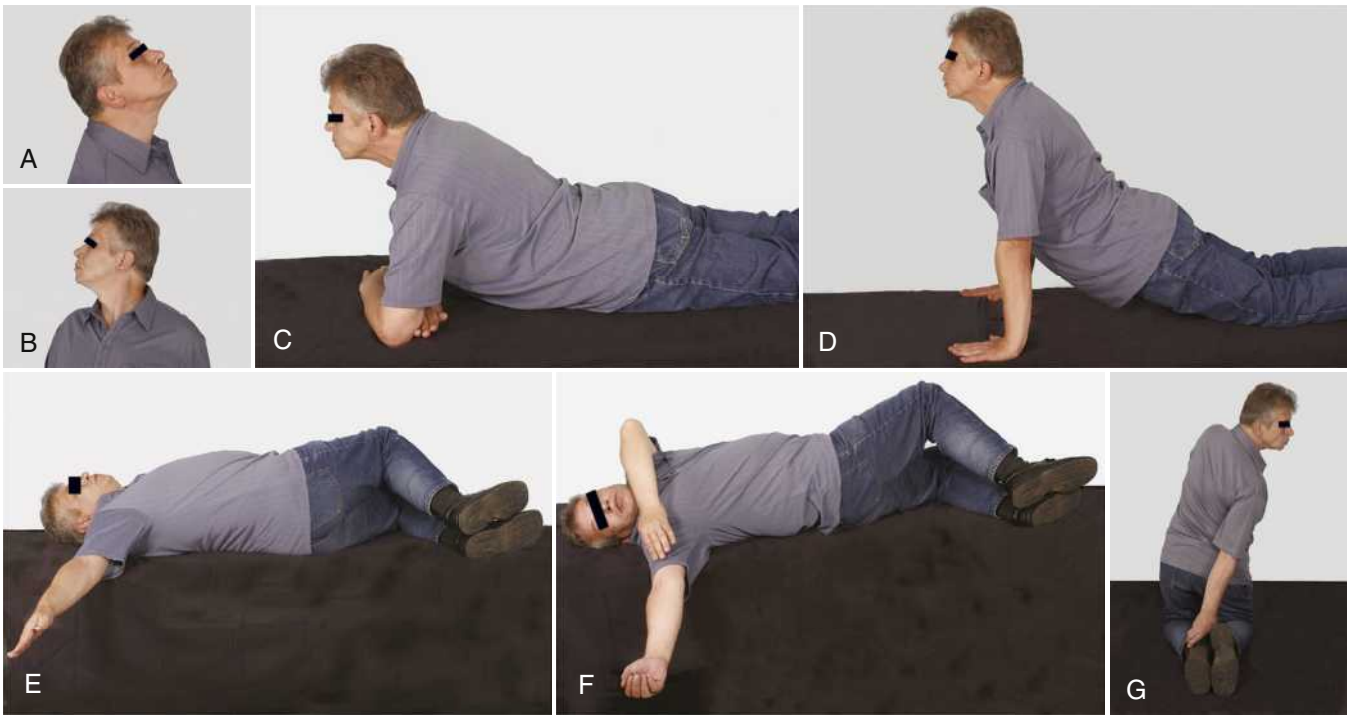

FIG. E9 An exercise sequence used in patients with ankylosing spondylitis. Cervical spine exercises include full extension **(A)** and rotation **(B).** A sequence of back extension **(C** and **D)** is followed by rotation in the lying **(E** and **F)** and upright kneeling **(G)** positions. Finally, breathing with the thoracic muscles is practiced (not shown). (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

Anorectal Fistula

BASIC INFORMATION

DEFINITION

An anorectal fistula is an inflammatory tract with a secondary (external) opening in the perianal skin and a primary (internal) opening in the anal canal at the dentate line. Anorectal fistulae usually originate as a complication of a perianal abscess, which develops from an infected anal crypt gland. If that abscess ruptures and the tract epithelializes, then a fistula develops. Anorectal fistulae can be classified as follows (based on their relationship to the anal sphincter complex):

- Intersphincteric: Fistula track passes within the intersphincteric plane to the perianal skin (most common)
- Transsphincteric (Fig. E1): Fistula track passes from the internal opening, through the internal and external sphincter, and into the ischiorectal fossa to the perianal skin (frequent)
- Suprasphincteric: After passing through the internal sphincter, fistula tract passes above the puborectalis and then tracts downward, lateral to the external sphincter, into the ischiorectal space to the perianal skin (uncommon); if abscess cavity extends cephalad, a supralevator abscess possibly palpable on rectal examination
- Extrasphincteric: Fistula tract passes from the rectum, above the levators, through the levator muscles to the ischiorectal space and perianal skin (rare)
- Submucosal: Originate at the level of the dentate line in an infected crypt not involving the sphincter muscles

With a horseshoe fistula, the tract passes from one ischiorectal fossa to the other behind the rectum.

SYNONYM

Fistula-in-ano

ICD-10CM CODES
K60.3 Anal fistula
K60.5 Anorectal fistula

EPIDEMIOLOGY & DEMOGRAPHICS

- Common in all ages (average age is 39 yr)
- Occurs twice as often in men as compared to women (12.1/100,000 vs. 5.5/100,000)
- Associated with inflammatory bowel disease and constipation
- Pediatric age group: More common in infants; boys more than girls

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute stage: Perianal swelling, pain with defecation and sitting, and fever
- Chronic stage: Pain, malodorous perianal drainage or bleeding, anal pruritus
- Tender, inflamed external fistulous opening, within 2 to 3 cm of the anal verge, with purulent or serosanguineous drainage on compression; the greater the distance from the anal margin, the greater the probability of a complicated upward extension
- Goodsall rule:
  1. Location of the internal opening related to the location of the external opening.
  2. With external opening anterior to an imaginary line drawn horizontally across the midpoint of the anus: Fistulous tract runs radially into the anal canal.
  3. With opening posterior to the transanal line: Tract is usually curvilinear, entering the anal canal in the posterior midline.
  4. Exception to this rule: An external anterior opening that is >3 cm from the anus. In this case the tract may curve posteriorly and end in the posterior midline.
- If perianal abscess recurs, presence of a fistula is suggested.

ETIOLOGY

- Most common: Nonspecific infection of anal crypt gland (skin or intestinal flora)
- Fistulas more common when intestinal microorganisms are cultured from the anorectal abscess
- Tuberculosis
- Lymphogranuloma venereum
- Actinomycosis
- Inflammatory bowel disease (IBD): Crohn disease, ulcerative colitis
- Trauma: Surgery (episiotomy, prostatectomy), foreign bodies, anal intercourse
- Malignancy: Carcinoma, leukemia, lymphoma
- Treatment of malignancy: Surgery, radiation

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anal abscess
- Anal ulcer or fissure
- Hidradenitis suppurativa
- Pilonidal sinus
- Bartholin gland abscess or sinus
- Infected perianal sebaceous cysts

WORKUP

- Digital rectal examination:
  1. Assess sphincter tone and voluntary squeeze pressure.
  2. Determine the presence of an extraluminal mass.
  3. Identify an indurated fistula tract.
  4. Palpate an internal opening or pit.
- Gentle probing of external orifice to avoid creating a false tract; 50% do not have clinically detectable opening
- Exam alone can be adequate for most simple anorectal fistulas
- Anoscopy
- Proctosigmoidoscopy to exclude inflammatory or neoplastic disease
- All studies done under adequate anesthesia

LABORATORY TESTS

- Complete blood count
- Rectal biopsy if diagnosis of IBD or malignancy suspected; biopsy of external orifice is useless

IMAGING STUDIES

- Transanal endosonography (EUS) can be useful to predict the amount of sphincter that would be divided if primary fistulotomy is performed and to identify undrained sepsis, complex anatomy, and high blind tracts (Fig. E2). MRI can be used to identify suprasphincteric or extrasphincteric tracts. MRI and EUS are more accurate in describing fistulas than clinical exam. CT lacks adequate resolution to identify tracts and their relationship to the sphincters and levators.
- Fistulography, in which contrast is injected into the external opening and the fistula course is traced with fluoroscopy, is rarely necessary in view of recent technological advancements.
- Colonoscopy or barium enema if:
  1. Diagnosis of IBD or malignancy is suspected
  2. History of recurrent or multiple fistulas
  3. Patient <25 yr
- Small bowel series: Occasionally obtained for reasons similar to previous advancements.

TREATMENT

NONPHARMACOLOGIC THERAPY

Sitz baths

PHARMACOLOGIC THERAPY (RARELY RECOMMENDED)

Immunomodulators (Infliximab)

ACUTE GENERAL Rx

- Treatment of choice: Surgery
- Broad-spectrum antibiotic given if:
  1. Cellulitis present
  2. Patient is immunocompromised
  3. Valvular heart disease present
  4. Prosthetic devices present
- Stool softener/laxative

CHRONIC Rx

- Surgery: Table E1 summarizes management strategy by fistula classification
- Surgical goals are as follows:
  1. Remove the fistula
  2. Prevent recurrence
  3. Preserve sphincter function
  4. Minimize healing time
- Methods for the management of anal fistulas: Fistulotomy, fistulectomy, setons (Fig. E3) (maintains fistula patent for drainage while spontaneous healing occurs), fibrin glue (clot formation within the fistulous tract), fistula plugs (Fig. E4) (promote closure of fistula), LIFT procedure, rectal advancement flaps, and colostomy

DISPOSITION

Outpatient surgery

REFERRAL

Refer to a surgeon with expertise in this area.

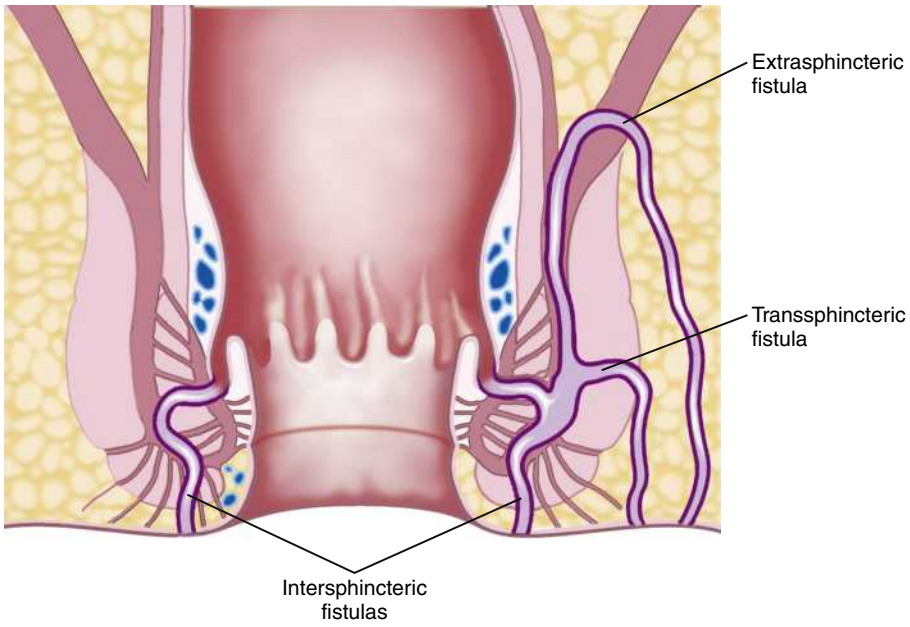

FIG. E1 Schematic depiction of the classification of fistula-in-ano. Fistulotomy is not appropriate for extrasphincteric fistulas, because it would leave the patient incontinent. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fortran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

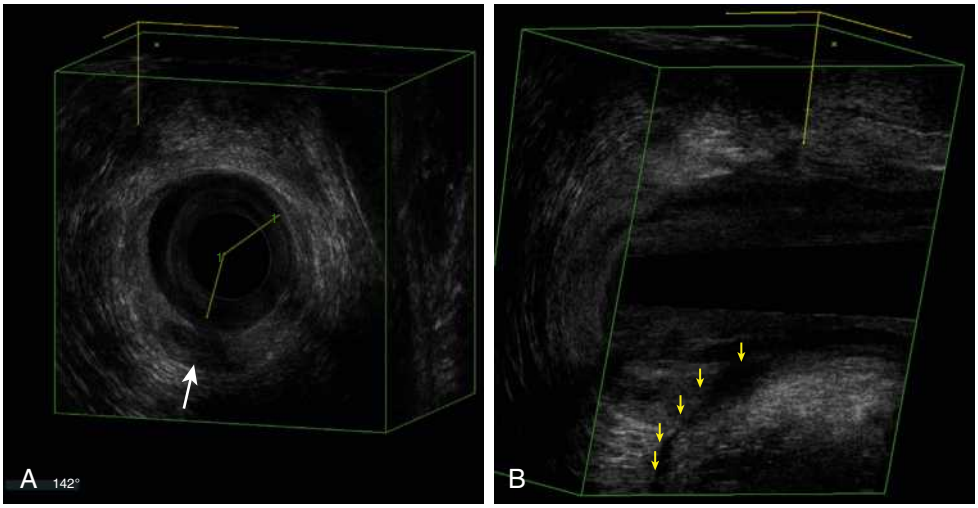

FIG. E2 Ultrasound of right posterior transsphincteric fistula. A, Coronal view revealing a 142-degree internal sphincter defect on the left side from a previous hemorrhoidectomy. The hypoechoic internal opening of a right transsphincteric fistula is noted with an arrow. Given the edge of the internal sphincter defect abuts the fistula tract, a LIFT procedure may not be feasible. **B,** Angled sagittal view showing the hypoechoic transsphincteric fistula. Note the internal opening nears the half length of the hyperechoic external sphincter; therefore a fistulotomy would not be appropriate. (Photo credit Amy Thorsen, MD, in Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.)

TABLE E1 Management Strategy by Fistula Classification

Type of Fistula	Fistulotomy	Seton *	LIFT	Advancement Flap	Fibrin Glue	Collagen Plug	Address Intraabdominal or Pelvic Source
Superficial/intersphincteric	•						
Low transsphincteric	•	•	•	•	•	•	
High transsphincteric		•	•	•	•	•	
Suprasphincteric		•		•		•	•
Extrasphincteric						•	•

LIFT, Ligation of intersphincteric fistula tract.
*Seton placement can be a first stage or definitive treatment option.
From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

FIG. E3 Blue setons placed through fistulous tracts in a patient with anal Crohn disease. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fortran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

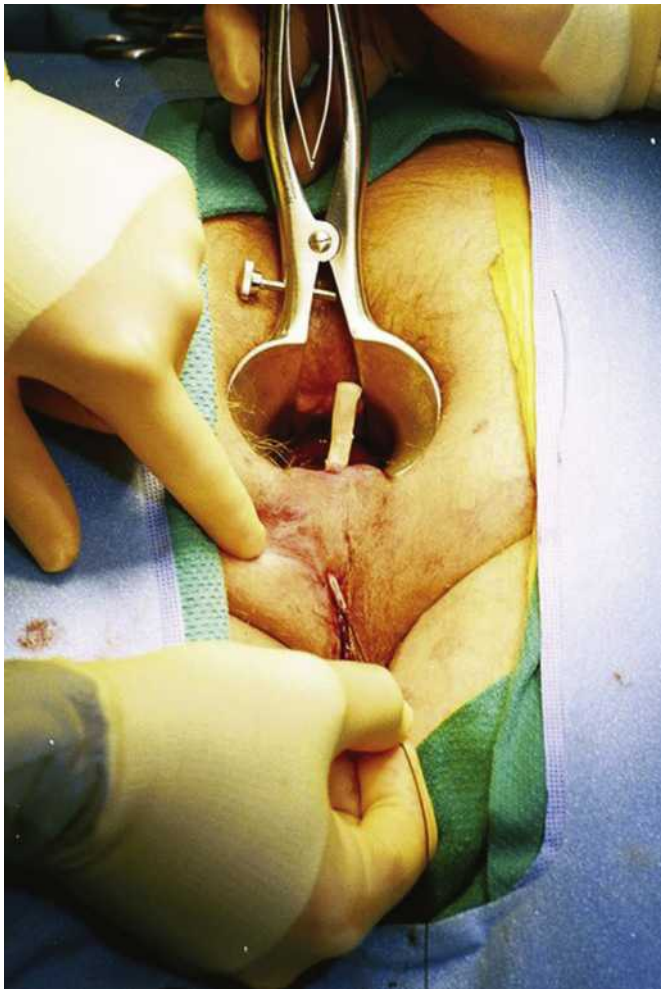

FIG. E4 Anal fistula plug being placed through an anterior anal fistula tract. Once it is pulled snugly through the tract, the plug is secured internally and the internal opening closed. Excess plug projecting externally is also trimmed. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fortran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

PEARLS & CONSIDERATIONS

COMMENTS

- HIV-positive and diabetic patients with perirectal abscesses/fistulas are true surgical emergencies.
- Risk of septicemia, Fournier's gangrene, and other septic complications make immediate drainage imperative.

Sneider EB, Maykel JA: Anal abscess and fistula, *Gastroenterol Clin N Am* 42:773-784, 2013.

BASIC INFORMATION

DEFINITION

Abnormal narrowing of the anal canal. Anorectal strictures can be classified based on severity and location (Table E1).

SYNONYMS

Anal stenosis
Küss disease

ICD-10CM CODE
K62.4 Stenosis of anus and rectum

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 5% to 10% of post-radical hemorrhoidectomy surgeries
RISK FACTORS: Previous anorectal surgery, inflammatory bowel disease, prior radiation, hemorrhoids

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- History:
  1. Most common symptom is pain with defecation
  2. Patients also may report bleeding, narrowing of stools, constipation, fecal incontinence, tenesmus, and urgency
  3. Important to ask about past anorectal surgeries, Crohn disease, or perianal trauma
- Physical examination:
  1. Visual inspection of the anus may demonstrate skin tags or chronic fissures
  2. Digital rectal examination will demonstrate a narrowed anal canal through which it is difficult to pass a lubricated finger
  3. In severe cases, examination under anesthesia may be required

TABLE E1 Classification of Anorectal Stricture

Severity	Location
Mild: Stricture present, but allows passage of well-lubricated finger or medium Hill-Ferguson retractor	**Low:** At least 0.5 cm distal to the dentate line
Moderate: Passage of well-lubricated finger or medium Hill-Ferguson retractor only with forceful dilation	**Middle:** 0.5 cm on either side of the dentate line
Severe: No passage of well-lubricated finger or medium Hill-Ferguson retractor	**High:** At least 0.5 cm proximal to the dentate line

Adapted from Liberman H, Thorson AG: How I do it. Anal stenosis. *Am J Surg* 179:325-329, 2000. In Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

ETIOLOGY

- Congenital malformation
- Fibrosis of anoderm or distal rectal mucosa due to a surgical procedure:
  1. Hemorrhoidectomy
  2. Low anterior resection
  3. Ileal pouch-anal anastomosis
  4. Anopexy
  5. Excision of perianal skin lesion
- Anal canal muscle hypertrophy
- Anal canal muscle spasm (anismus) secondary to anal fissure
- Neoplasia:
  1. Bowen disease
  2. Paget disease
  3. Anal squamous cell carcinoma
  4. Rectal adenocarcinoma
  5. Condyloma acuminata
- Inflammation:
  1. Anal fissure
  2. Crohn disease
  3. Tuberculosis
  4. Actinomycosis
  5. Lymphogranuloma venereum
  6. Chronic suppuration
- Trauma:
  1. Radiation therapy
  2. Perineal burns
  3. Hot water enemas
  4. Ibuprofen suppositories
  5. Chronic laxative abuse
- Sexually transmitted disease
- Box E1 summarizes common causes of anorectal strictures

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anorectal stricture/stenosis
- Neoplasm

BOX E1 Cause of Anorectal Stricture

Surgical Procedures
Hemorrhoidectomy
Low anterior resection
Ileal pouch-anal anastomosis
Anopexy
Excision of perianal skin lesions

Neoplastic
Bowen disease
Paget disease
Anal squamous cell carcinoma
Rectal adenocarcinoma
Condyloma acuminata

Inflammatory
Anal fistula
Crohn disease
Tuberculosis
Actinomycosis
Lymphogranuloma venereum

Trauma

Perineal burns
Hot water enemas
Ibuprofen suppositories
Chronic laxative abuse

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

- Inflammatory bowel disease
- Trauma

WORKUP

- Hydration, fiber supplementation, and stool softeners should be started in all patients regardless of ultimate etiology.
- Suspicious lesions should be biopsied.

LABORATORY TESTS

None

IMAGING STUDIES

None

TREATMENT

NONPHARMACOLOGIC THERAPY

- Manual dilation using digital method or commercial dilators may be started in the clinic or operating room and continued on an outpatient basis
- Resection of neoplasm
- Stricturoplasty
- Anoplasty

CHRONIC Rx

For mild disease, stool softeners, fiber supplementation, and dietary modification are all that is necessary.

COMPLEMENTARY AND ALTERNATIVE MEDICINE

None

DISPOSITION

Mild strictures can be treated on an outpatient basis in clinic; moderate to severe strictures require colorectal surgical evaluation.

REFERRAL

Referral is indicated when there is concern for neoplasm, patients who fail conservative medical management, or if the provider is unable to pass a lubricated finger into the rectum.

Anorexia Nervosa ALG PTG

BASIC INFORMATION

DEFINITION

Anorexia nervosa is a psychiatric disorder characterized by abnormal eating behavior, severe self-induced weight loss, and a specific psychopathology (see "Workup").

ICD-10CM CODES

F50.00	Anorexia nervosa, unspecified
F50.01	Restricting type
F50.02	Binge-eating/purging type

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE/PREVALENCE (IN U.S.):

- Anorexia nervosa occurs in 0.2% to 1.3% of the general population, with an annual incidence of 5 to 10 cases per 100,000 persons.
- Participation in activities that promote thinness (athletics, modeling) is associated with a higher incidence of anorexia nervosa.

PREDOMINANT SEX: Female:male ratio is 9:1. Approximately 0.5% to 1% of women between the ages of 15 and 30 yr have anorexia nervosa.

PREDOMINANT AGE: Adolescence to young adulthood is the predominant age. Mean age of onset is 17 yr. Approximately 0.5% to 1% of college-aged women have anorexia nervosa.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Eating disorders can affect every organ system. Primary care physicians must be skilled at recognizing this disorder because patients with mild cases usually present with nonspecific symptoms such as asthenia, cold intolerance, lack of energy, or dizziness. Children and adolescents are at particular risk due to their active phase of growth and development. The physical examination may be normal in the early stages or in mild cases. Patients with moderate to severe anorexia have the following physical characteristics:

- Patient is emaciated and bundled in clothing.
- Skin is dry and has excessive growth of lanugo. Skin may also be yellow-tinged from carotenodermia.
- Brittle nails, thinning scalp hair are present.
- Bradycardia, hypotension, hypothermia, and bradypnea are common.
- Female fat distribution pattern is no longer evident.
- Axillary and pubic hair is preserved.
- Peripheral edema may be present.

ETIOLOGY

- Etiology is unknown, but probably multifactorial (sociocultural, psychological, familial, and genetic factors).
- A history of sexual abuse has been reported in as many as 50% of patients with anorexia nervosa.
- Psychological factors: Anorexics often have an incompletely developed personal identity. They struggle to maintain a sense of control over their environment, they usually have a low self-esteem, and they lack the sense that they are valued and loved for themselves.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other eating disorders (bulimia nervosa, binge eating disorder [Table E1])
- Substance abuse
- Depression with loss of appetite
- Obsessive compulsive disorder
- Schizophrenia
- Conversion disorder
- Occult carcinoma, lymphoma
- Endocrine disorders: Addison disease, diabetes mellitus, hypothyroidism or hyperthyroidism, panhypopituitarism
- Gastrointestinal disorders: Celiac disease, Crohn disease, intestinal parasitosis
- Infectious disorders: AIDS, tuberculosis
- A clinical algorithm for the evaluation of anorexia is described in Section III

WORKUP

- A diagnosis can be made by using the following *DSM-5* diagnostic criteria for anorexia nervosa.
  1. Restriction of energy intake relative to requirements, leading to a significantly low body weight in the context of age, sex, developmental trajectory, and physical health. Significantly low weight is defined as a weight that is less than minimally normal or, for children or adolescents, less than that minimally expected.
  2. Intense fear of gaining weight or becoming fat, or persistent behavior that interferes with weight gain, even though at a significantly low weight.
  3. Disturbance in the way in which one's body or shape is experienced, undue influence of body weight or shape on self-evaluation, or persistent lack of recognition of the seriousness of the current low body weight.
- Specify type:
  1. Restricting type: During the last 3 mo, the individual has not engaged in recurrent episodes of binge eating or purging behavior (i.e., self-induced vomiting or the misuse of laxatives, diuretics, or enemas). This subtype describes presentations in which weight loss is accomplished primarily through dieting, fasting, and/or excessive exercise.
  2. *Binge-eating/purging type:* During the last 3 mo, the individual has engaged in recurrent episodes of binge eating or purging behavior (i.e., self-induced vomiting or the misuse of laxatives, diuretics, or enemas).
- Severity level: See "Acute General Rx" section

The SCOFF questionnaire is a screening tool for eating disorders used in England. It consists of the following five questions:

1. Do you make yourself ***s***ick because you feel full?
2. Have you lost ***c***ontrol over how much you eat?
3. Have you lost more than ***o***ne stone (approximately 6 kg) recently?
4. Do you believe yourself to be ***f***at when others say you are thin?
5. Does ***f***ood dominate your life?

A positive response to two or more questions has a reported sensitivity of 100% for anorexia and bulimia and an overall specificity of 87.5%.

In college-aged women a positive response to any of the following screening questions also warrants further evaluation:

1. How many diets have you been on in the past year?
2. Do you think you should be dieting?
3. Are you dissatisfied with your body size?
4. Does your weight affect the way you think about yourself?

Baseline ECG should be performed on all patients with anorexia nervosa. Routine monitoring of patients with prolonged QT interval is necessary; sudden death in these patients is often caused by ventricular arrhythmias related to QT interval prolongation.

A dual-energy x-ray absorptiometry (DEXA) scan to screen for osteopenia should be considered after 6 mo of amenorrhea in patients suspected of anorexia nervosa.

LABORATORY TESTS

- In mild cases, laboratory findings may be completely normal.
- Endocrine abnormalities:
  1. Decreased follicle-stimulating hormone, luteinizing hormone, T_4, T_3, estrogens, urinary 17-OH steroids, estrone, and estradiol
  2. Normal free T_4, thyroid-stimulating hormone
  3. Increased cortisol, growth hormone, rT_3, T_3RU
  4. Absence of cyclic surge of luteinizing hormone

TABLE E1 Diagnostic Features of Eating Disorders

Anorexia nervosa	Body weight willfully maintained below normal level Abnormal perception of body morphology Intense fear of weight gain Amenorrhea
Bulimia nervosa	Large uncontrolled eating binges at least twice weekly Inappropriate compensatory behavior (e.g., vomiting, purging)
Binge eating disorder	Large uncontrolled eating binges at least twice weekly No regular inappropriate compensatory disorders Marked distress about binges

Modified and updated from Besser CM, Thorner MO: *Comprehensive clinical endocrinology,* ed 3, St Louis, 2002, Mosby.

- Leukopenia, thrombocytopenia, anemia, reduced erythrocyte sedimentation rate, reduced complement levels, and reduced CD4 and CD8 cells may be present.
- Metabolic alkalosis, hypocalcemia, hypokalemia, hypomagnesemia, hypercholesterolemia, and hypophosphatemia may be present.
- Increased plasma β-carotene levels are useful to distinguish these patients from others on starvation diets.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- A multidisciplinary approach with psychological, medical, and nutritional support is necessary.
- A goal weight should be set and the patient should be initially monitored at least once a week in the office setting. The target weight is 100% of ideal body weight (BW) for teenagers and 90% to 100% for older patients.
- Weight gain should be gradual (1 to 3 lb/wk) to prevent gastric dilation. Begin with 800 to 1200 kcal in frequent small meals (to avoid bloating sensation), then increase calories to 1500 to 3000 depending on height and age.
- Add, as necessary, vitamin and mineral supplements.
- In severe cases, total parenteral nutrition must be used (starting at 800 to 1200 kcal/day).
- Electrolyte levels should be strictly monitored.
- Mealtime should be a time for social interaction, not confrontation.
- Postprandially, sedentary activities are recommended. The patient's access to a bathroom should be monitored to prevent purging.

ACUTE GENERAL Rx

- Criteria to decide on the appropriate initial course of treatment for patients with anorexia nervosa are usually based on the presence of complications, percentage of ideal BW, and severity of body image distortion. According to *DSM-5*,[1] the minimum level of severity is based, for adults, on current body mass index (BMI; see below) or, for children and adolescents, on BMI percentile. The level of severity may be increased to reflect clinical symptoms, the degree of functional disability, and need for supervision.
  Mild: BMI ≥17 kg/m^2
  Moderate: BMI 16 to 16.99 kg/m^2
  Severe: BMI 15 to 15.99 kg/m^2
  Extreme: BMI <15 kg/m^2
- Outpatient treatment is adequate for most patients.
- Indications for inpatient-level care are described under "Referral" section and summarized in Table E2.
- Medically stable patients who are within 85% of ideal BW can be followed up by the primary care physician at 3- or 4-wk intervals, which can be lengthened as the patient improves.

[1] American Psychiatric Association: Desk Reference to the Diagnostic Criteria from DSM-5, Arlington, VA, 2013, American Psychiatric Association.

- Pharmacologic treatment generally has no role in anorexia nervosa unless major depression or another psychiatric disorder is present. Selective serotonin reuptake inhibitors can be used to alleviate the depressed mood and moderate obsessive-compulsive behavior in some individuals.

CHRONIC Rx

- Psychotherapy continued for years and focused specifically on self-image, family and peer interactions, and relapse prevention is an integral part of a successful recovery.
- Family therapy is also recommended, especially in younger patients.

DISPOSITION

- The long-term prognosis is generally poor and marked by recurrent exacerbations. The percentage of patients with anorexia nervosa who fully recover is modest. Most patients continue to have a distorted body image, disordered eating habits, and psychic difficulties.
- Most patients with anorexia nervosa will recover menses within 6 mo of reaching 90% of their ideal BW. It is important to note that patients with anorexia nervosa can become pregnant despite amenorrhea.
- Mortality rates vary from 5% to 20% and are six times that of peers without anorexia. Frequent causes of death are electrolyte abnormalities, starvation, or suicide.
- Factors that predict improved outcome in patients with eating disorders include early age at diagnosis, brief interval before initiation of treatment, good parent-child

TABLE E2 Clinical Signs and Criteria Warranting Inpatient-Level Care to Stabilize or Treat an Eating Disorder

Domain	General Symptom[a]	Example[b]
Weight	Substantially low weight for height and age Rapidly falling weight	<75% to 85% expected body weight for height and age
Behavioral	Acute food or water refusal Episodes of bingeing and purging of very high and/or escalating frequency Compensatory behaviors likely to result in acute and severe medical complications	Bingeing and/or vomiting multiple times per day resulting in social or occupational impairment and/or serious medical complications; inappropriate withholding of insulin
Other medical compromise	Abnormal vital signs reflecting nutritional compromise Severe medical complications	Severe hematemesis Severe neutropenia and/or thrombocytopenia Severe hypokalemia Uncontrolled type I diabetes Syncope
Psychiatric comorbidity and risk of self-harm	Substantial risk of self-harm or suicide Comorbid psychiatric illness resulting in safety risk or seriously undermining treatment Inability to adhere to treatment plan that will sustain minimal level of safety	Comorbid substance use escalating in the setting of treatment for the eating disorder
Treatment-related	Lack of clinically meaningful progress in an outpatient setting resulting in social or occupational impairment or medical risk Necessity of close supervision to maintain symptom control Previously agreed-on criterion for hospitalization based on patient history	An adolescent's low weight poses risk for decreased peak bone mass or short stature Sustained or persistent inability to eat without supervision or to abstain from intractable purging after food intake Reaching a threshold weight at which the patient repeatedly has rapidly deteriorated

[a] These criteria may be sufficient but do not necessarily need to be present to indicate inpatient care.
[b] Weight, vital signs, metabolic, and other parameters for hospitalization are best interpreted in the context of the patient's overall health, medical and psychiatric history, support systems, and engagement in treatment.
Stern TA et al: *Massachusetts General Hospital handbook of general hospital psychiatry,* ed 7, Philadelphia, 2018, Elsevier.

relationships, and having other healthy relationships with friends or therapists.
- A prolonged QT interval is a marker for risk of sudden death.

REFERRAL

Hospitalization should be considered in the following situations:
- Severe dehydration or electrolyte imbalance
- ECG abnormalities (prolonged QT interval, arrhythmias)
- Significant physiologic instability (hypotension, orthostatic changes)
- Intractable vomiting, purging, or bingeing
- Suicidal thoughts
- Weight loss exceeding 30% of ideal BW and unresponsiveness to outpatient treatment
- Rapidly progressing weight loss (>2 lb in a week)
- Failure to progress in nutritional rehabilitation in outpatient treatment

RELATED CONTENT

Anorexia Nervosa (Patient Information)
Binge Eating Disorder (Related Key Topic)
Bulimia Nervosa (Related Key Topic)

AUTHOR: **Fred F. Ferri, MD**

BASIC INFORMATION

DEFINITION

Anorexia-cachexia is a complex metabolic syndrome associated with underlying malignancy and is characterized by loss of appetite and ongoing loss of skeletal muscle mass, with or without loss of fat mass that can be partially, but not entirely, reversed by conventional nutritional support.

SYNONYM

Cancer cachexia

ICD-10CM CODE
R64 Cachexia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Estimates of the prevalence of cancer cachexia vary widely due to variable diagnostic criteria used in prior studies. In one study of 405 patients, the incidence of cachexia ranged from 12% to 85% using different available definitions. In another study, more than half of 644 cancer patients were reported as having cachexia using anorexia and weight loss exceeding 5% of premorbid weight. The highest incidence is reported in patients with lung and gastrointestinal cancers.

ETIOLOGY

In cancer patients, anorexia is common and results in decreased oral intake and malnourishment. Cancer cachexia is characterized by an upregulation of muscle proteolysis and lipolysis due to an increased inflammatory response from cytokines (interleukins [IL-6 and IL-1] and tumor necrosis factor α [TNF- α)]. These cytokines activate the ubiquitin-proteasome pathway via nuclear factor kappa B, resulting in a protein degradation pathway in the myocytes. At the same time, protein synthesis is downregulated by the human myogenic differentiation protein, MyoD. Furthermore, the increased cytokine levels induce an overall hypermetabolic state and shift the balance toward catabolism.

GENETICS: In patients with elevated inflammatory markers, cachexia is associated with specific vitamin D receptor polymorphisms, thus representing a possible early clinical predictor phenomenon for the development of a more aggressive form. Polymorphisms resulting in an increase in levels of inflammatory cytokines, a decrease in lean or fat mass, and decreased survival in cancer are likely to be cachexia-prone variants. However, to date, no specific single nucleotide polymorphisms (SNPs) have been found in association with cancer cachectic patients.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Starvation
- Malabsorption
- Hyperthyroidism
- Anorexia nervosa
- Depression

WORKUP

Patients can be categorized into three consecutive stages of cancer cachexia (Fig. 1): Precachexia, cachexia, and refractory cachexia using available cachexia staging systems. Furthermore, there are five domains to assess including: Food intake, catabolic derangements, functional and psychosocial impact, and assessments of body composition including stores of adipose tissue and muscle mass. A diagnosis can be made in a patient with weight loss >5% in the absence of starvation, BMI <20 and 2% weight loss, or appendicular skeletal muscle index consistent with sarcopenia and >2% weight loss.

LABORATORY TESTS

- Complete blood count, complete chemistry panel including albumin and prealbumin
- Inflammatory markers including ESR and C-reactive protein
- Endocrine assessment with TSH, cortisol, ACTH, testosterone

IMAGING STUDIES

CT or MR imaging of the abdomen can be used to assess for sarcopenia by analyzing the body and muscle composition

TREATMENT

The mainstay of treatment is directed at aggressive nutritional and supportive therapy (Fig. 2). Functional causes of malabsorption or gastrointestinal obstruction should be evaluated at the start. It has been proposed that the *T.A.R.G.E.T.* approach, encompassing different domains, namely *Teaching, Awareness, Recognition, Genetics, Exercise/Early intervention* and *Treatment* of cancer cachexia, should be utilized in all patients.

NONPHARMACOLOGIC THERAPY

- The general approach is to increase caloric intake by encouraging frequent (up to 5 to 6 times), small, and calorie-dense meals during the day along with supplemental liquid nutrition typically utilized alongside consultation with nutritionists.
- Physical activity may attenuate the effects of cachexia by modulating muscle metabolism, insulin sensitivity, and inflammation. In particular, exercise has been shown to have antiinflammatory properties, preserve muscle mass and function, enhance protein synthesis, decrease protein catabolism, and contribute to a better muscle performance.

ACUTE GENERAL Rx

- Multimodal interventions should be scheduled in parallel with anticancer therapies and may consist of nutritional intervention and multitargeted pharmacologic therapies.
- Enteral nutrition should be started if undernutrition already exists or if food intake is markedly reduced for more than 1 to 2 wk. When enteral nutrition cannot be effectively used, parenteral nutrition may be considered instead as a supporting measure or as total nutritional requirement.
- Appetite stimulants are the mainstay of pharmacologic intervention in cancer cachexia. Glucocorticoids have been extensively studied in patients with advanced cancer and are known to stimulate the appetite. Prednisone (at 20 to 40 mg/day) or dexamethasone (at 2 to 4 mg/day) are used commonly, but major side effects include insulin resistance, immune suppression, muscle myopathy, and adrenal insufficiency.
- Megestrol acetate, an appetite stimulant with progestational and antigonadotropic effects, has been shown to slightly improve appetite and increase weight but does not improve lean body mass or quality of life. Major complications include increased risk for thromboembolism, adrenal insufficiency, and hypogonadism in male patients.
- Dronabinol, a constituent of cannabis, has been studied for appetite stimulation in cancer patients, but results from large studies have revealed no major benefit.
- The psychiatric drugs mirtazapine and olanzapine both are potential therapies for cancer patients with anorexia-cachexia syndrome. Mirtazapine-treated patients gain weight and develop an improved appetite in some cases. Olanzapine treatment of cancer patients with cachexia who were receiving active chemotherapy showed a trend toward improved weight and may be useful for patients on chemotherapy who have difficult-to-control nausea and weight loss.
- Treatment with the NSAID celecoxib has resulted in weight gain, increased BMI, and improved quality of life. NSAIDs are frequently incorporated into combination drug therapy for cancer cachexia along with megestrol. A recent systematic review identified four studies that reported some evidence for the therapeutic benefits of NSAIDs in terms of weight gain, survival, quality of life, and inflammatory markers, but evidence was lacking for widespread use of NSAIDs in clinical practice.
- Anamorelin, a novel ghrelin-receptor agonist, has been evaluated in two large randomized trials in patients with advanced non–small cell lung cancer and cachexia. Although the trial failed to meet the primary endpoint, anamorelin significantly increased lean body mass, but not handgrip strength in these patients, and can be considered as an option.

CHRONIC Rx

- Nutritional supplements such as amino acids (l-glutamine, l-arginine, l-carnitine) have been evaluated with inconclusive results.
- Omega-3 fatty acids, eicosapentaenoic acid (EPA), and docosahexaenoic acid (DHA), which are found in fish oil, have been also investigated with inconclusive results.

- Ongoing exercise and rehabilitation programs need to be offered to all patients.

REFERRAL

- Nutritionists and cachexia clinics (if available).
- Palliative care specialists.

PEARLS & CONSIDERATIONS

- Cancer cachexia is an underrecognized problem present in up to half of all advanced cancer patients. Up to 1 in 5 cancer patients can die directly due to the effects of cancer cachexia.
- Multimodal intervention in early identified precachexia patients may prove to be beneficial.

AUTHOR: **Ritesh Rathore, MD**

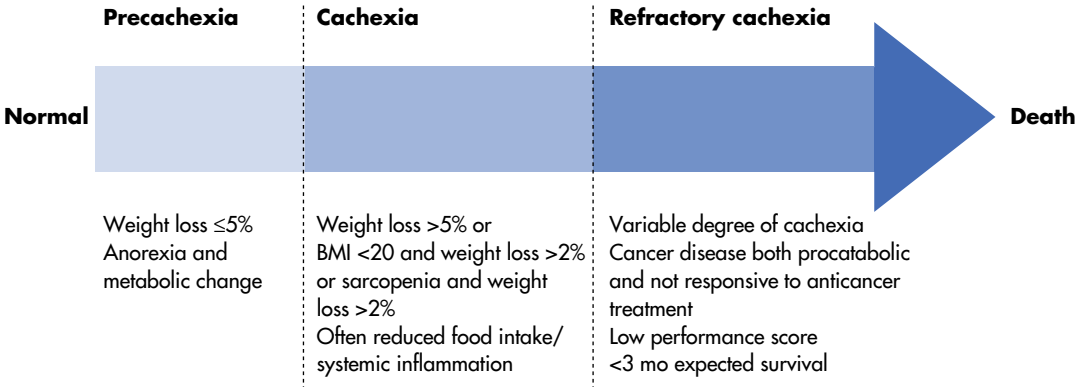

FIG. 1 Stages of anorexia-cachexia syndrome of malignancy. Cachexia represents a spectrum through which not all patients will progress. At present, there are no robust biomarkers to identify those precachectic patients who are likely to progress further or the rate at which they will do so. Refractory cachexia is defined essentially on the basis of the patient's clinical characteristics and circumstances. *BMI,* Body mass index. (From Fearon K et al: Definition and classification of cancer cachexia: an international consensus, *Lancet Oncol* 12(5):489-95, 2011.)

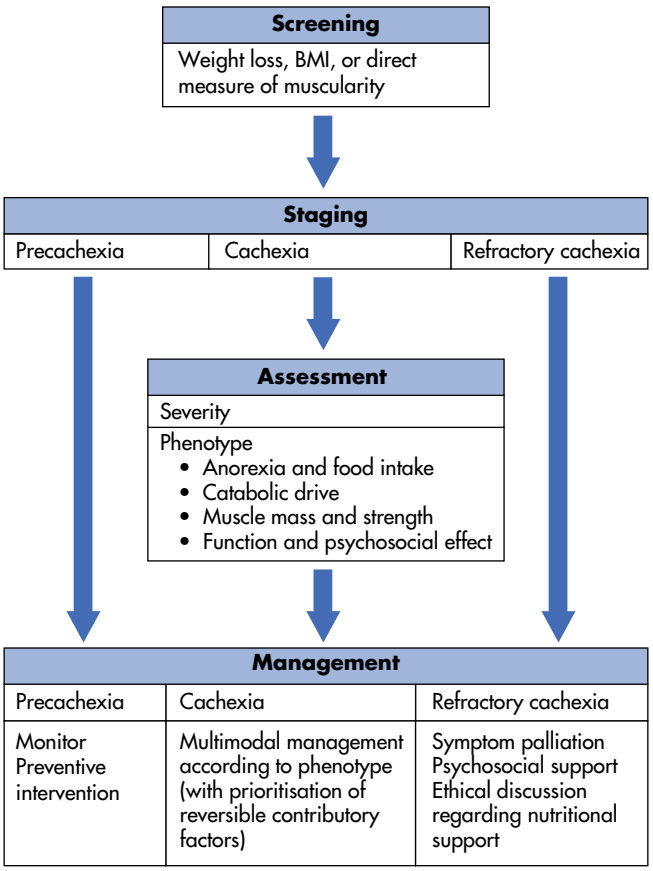

FIG. 2 Management of anorexia-cachexia syndrome of malignancy. Patients should be screened for cachexia, then undergo detailed assessment. All patients require optimum oncological and general medical management. Once patients with cachexia have been phenotyped, a detailed multimodal management plan (including nutrition, exercise, antiinflammatory strategies, and other adjuncts) can be established. *BMI,* Body mass index. (From Fearon K et al: Definition and classification of cancer cachexia: an international consensus, *Lancet Oncol* 12(5):489-95, 2011.)

Anoxic Brain Injury

BASIC INFORMATION

DEFINITION

Anoxic brain injury occurs when a decrease in either blood flow or oxygen causes cerebral ischemia. The inadequate delivery of nutrients and oxygen to cerebral tissue commonly reflects defects in either cardiac circulation or respiratory function, or defects in both.

SYNONYMS

Hypoxic-ischemic injury
Anoxic encephalopathy
Cerebral hypoxia
Hypoxia of brain
Perinatal or intrapartum asphyxia (pediatric)

ICD-10CM CODE
G93.1 Anoxic brain damage, not elsewhere classified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:
- Variable based on diagnostic criteria.
- 424,000 out-of-hospital cardiac arrests per yr in the U.S.

PREVALENCE:
- Sequelae of anoxic brain injury may include vegetative state, which varies in prevalence from 40 to 168 per 1 million population, depending on definition used.
- Other sequelae may include death from either cardiac arrest or loss of whole-brain function (brain death) or progression to either minimally conscious state or dementia.
- Recovery is rare after 3 months of vegetative state, with life expectancy of 2 to 5 yr.

RISK FACTORS: Same as risk factors for cardiorespiratory arrest: age, race, hypertension, hyperlipidemia, tobacco use, drug or alcohol abuse, and physical inactivity.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Variable depending on degree of insult.
- Patient typically initially in coma and then may either recover awareness and wakefulness with variable degrees of cognitive or physical impairment, may progress to a vegetative state or a minimally conscious state, or may die due to cardiopulmonary arrest or loss of whole brain function (brain death).
- Coma: Eyes-closed state of both unconsciousness and unawareness with loss of sleep-wake cycles.
- Minimally conscious state: Altered state of awareness with normal sleep-wake cycles and intermittent interactivity with the environment; patient may intermittently follow simple commands and maintain visual tracking.
- Vegetative state (also known as unresponsive wakefulness): Altered state of awareness with normal sleep-wake cycles but with complete loss of both cognitive awareness and ability to interact with environment; persistent vegetative state is the term used for vegetative state after anoxic injury of between 1 and 3 months' duration, and permanent vegetative state is the term used for a vegetative state persisting beyond 3 months. A vegetative state due to traumatic brain injury is permanent only after 12 months.
- Brain death: Irreversible loss of both cortical and brainstem function manifesting as loss of awareness, cranial reflexes, and motor responses; brain death meets the legal criteria for death in U.S. jurisdictions. EEG is isoelectric; there is no intracerebral blood flow.

ETIOLOGY

- Ischemia (decreased cerebral perfusion): Myocardial infarction, hemorrhage, shock, high intracranial pressure
- Hypoxia (decreased oxygenation): Drowning, strangulation, aspiration, carbon monoxide poisoning
- Fig. E1 shows categories of mechanisms proposed to be involved in the evolution of secondary damage after severe traumatic brain injury in infants and children

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of encephalopathy, including toxic, metabolic, infectious, or neoplastic causes; nonconvulsive status epilepticus; hypothermia
- Histotoxic hypoxia, the inability to utilize oxygen despite adequate delivery to cerebral tissue; i.e., cyanide poisoning

WORKUP

- Neurologic examination (coma examination) to ascertain level of encephalopathy
- Systemic evaluation for causes of cardiorespiratory failure
- Laboratory studies (listed in the following) to evaluate alternate causes of encephalopathy
- Imaging studies: MRI of brain or CT of head (if MRI cannot be obtained)

LABORATORY TESTS

Urine drug screen, serum metabolic profile, ammonia, complete blood count, coagulation panel, liver function test, arterial blood gas, blood alcohol panel, serum neuron-specific enolase (if available)

IMAGING STUDIES

- Imaging is usually not revealing within first 24 hr of an anoxic event
- Head CT without contrast (Fig. E2): Repeat 24 hr after anoxic event to evaluate for stroke, trauma, hemorrhage, or cerebral edema
- MRI of brain (Fig. E3): Obtain if head CT scan unrevealing; may show cortical necrosis and infarcts of the basal ganglia

OTHER STUDIES

- EEG: To assess for non-convulsive status epilepticus
- Somatosensory evoked potentials (SSEP; aka, N20 response): Obtain 24 to 72 hr after anoxic event

TREATMENT

NONPHARMACOLOGIC THERAPY

- Hypothermia: Evidence suggests that inducing hypothermia 32° C to 34° C (89.6° F to 93.2° F) for 24 hr following anoxic brain injury reduces metabolic demand and may improve prognosis for recovery. However, recent

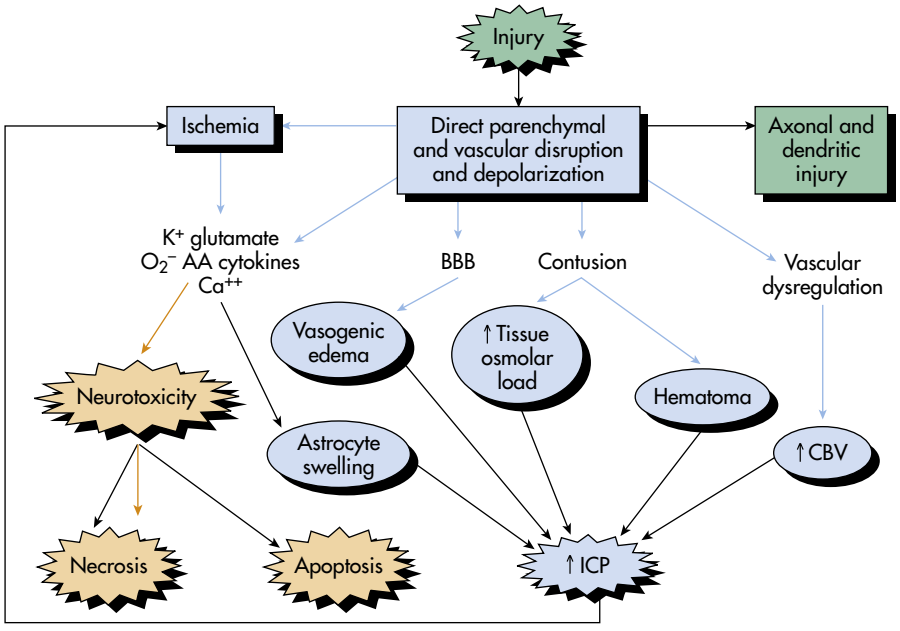

FIG. E1 Categories of mechanisms proposed to be involved in the evolution of secondary damage after severe traumatic brain injury in infants and children. Three major categories for these secondary mechanisms are (1) ischemia, excitotoxicity, energy failure, and cell death cascades; (2) cerebral swelling; and (3) axonal injury. *AA,* amino acid; *BBB,* blood-brain barrier; *CBV,* capillary blood volume; *ICP,* intracranial pressure. (From Fuhrman BP: *Pediatric critical care,* ed 4, St Louis, 2011, Mosby.)

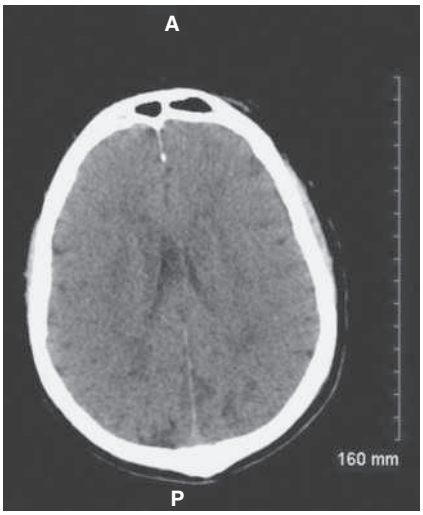

FIG. E2 Computed tomography without contrast of a patient 1 day after pulseless electrical activity showing diffuse sulci effacement and loss of gray-white matter differentiation indicating cerebral edema. Diffuse white and gray matter hypodensities are also present. The patient remained comatose and life support was eventually withdrawn.

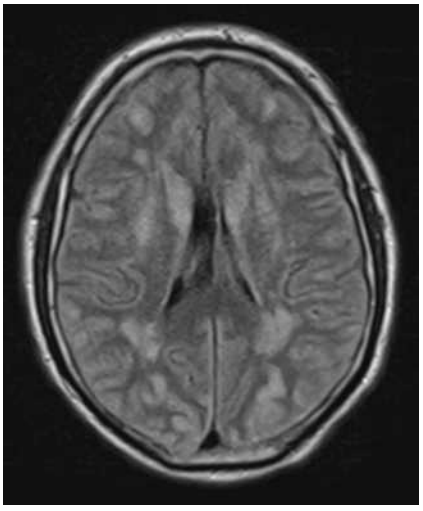

FIG. E3 Magnetic resonance image fluid-attenuated inversion recovery of a patient 1 day after pulseless electrical activity showing bilateral multiple cortical, subcortical, gray and white hyperintensities. The patient remained comatose and life support was eventually withdrawn.

meta-analysis suggests that the true risk-benefit of therapeutic hypothermia is unclear and is a topic of debate.
- Complications from hypothermia include bradycardia, hemodynamic instability, coagulopathy, infection, hyperglycemia, and hypokalemia.
- Contraindications for hypothermia: Active hemorrhage, hemodynamic instability, sepsis, or trauma.
- Indication for hypothermia: Patients who have been resuscitated from a cardiac arrest with VF/VT as the presenting rhythm.
- Hyperbaric oxygen is used in carbon monoxide poisoning.

ACUTE GENERAL Rx

- Supportive care: ABCs, secure airway, cardiopulmonary support in the critical care unit.
- Control seizures with antiepileptic medications (may need midazolam or propofol drip for severe, uncontrolled seizures).
- Treat myoclonus with clonazepam 8 to 12 mg daily in divided doses; levetiracetam and valproic acid may be used for myoclonic status epilepticus. Treatment of myoclonus due to cardiac arrest does not change neurologic prognosis.

CHRONIC Rx

- Maintain adequate nutrition, normothermia (if not utilizing therapeutic hypothermia) infection precautions; provide deep vein thrombosis and gastric ulceration prophylaxis
- Physical, occupational, and speech therapy as indicated per prognosis and patient ability
- May consider withdrawal of critical care and implementation of palliative care per prognosis, family consultation, and respect for autonomy and dignity of the patient

PROGNOSIS

- Out-of-hospital cardiopulmonary resuscitation (CPR) for cardiac arrest has a success rate of <10%.
- There is no standardized battery of testing to quantify anoxic injury and reliably predict outcomes.
- Anoxia time, duration of CPR, and cause of cardiac arrest are related to poor outcome after CPR but are not sufficient for prognosis.
- Strong predictors of poor outcome (evidence level A or B) (assuming patient did not undergo therapeutic hypothermia) are the following:
  1. Presentation with myoclonus status epilepticus within the first 24 hr following injury
  2. Absence of bilateral cortical SSEPs (N20 response) anytime
  3. Absent papillary or corneal reflexes, or absent or extensor motor responses after 72 hr following injury
  4. Serum neuron-specific enolase levels >33 μg/L 24 to 72 hr following injury
- Neuroimaging and EEG are sensitive but not specific predictors of outcome.
- Burst-suppression pattern or flat-line EEG carries bad prognosis, while reactive EEG to noxious stimuli predicts favorable outcome.
- The prognostic value of these findings and the timing of exam changes after therapeutic hypothermia. Timing should, at a minimum, be factored from the time the patient was fully rewarmed rather than from the time of initial cardiopulmonary arrest. The window for concluding poor prognosis based on examination after hypothermia may be extended further based on future studies. Furthermore, the reliability of NSE post-hypothermia has been called into question.

DISPOSITION

Varies per extent of insult from death to long-term care facility to acute rehabilitation to return to home

REFERRAL

Referral to a neurologist is appropriate for help with prognostication.

PEARLS & CONSIDERATIONS

COMMENTS

When assessing prognosis, use caution if patient is being treated with anesthetic agents or other depressants of consciousness, including anticonvulsants. Also, consider the impact of therapeutic hypothermia on the timing of prognostication. Thus serial neurologic exams are integral to best-practice care. When examining patients and determining prognosis, account for medications and illicit drugs that may depress consciousness and awareness as well as metabolic derangements that may affect the metabolism of pharmacologic agents or illicit drugs.

PREVENTION

CPR, risk factor modification, induced hypothermia

PATIENT & FAMILY EDUCATION

Consult with family members regularly and provide accurate assessment of prognosis.

AUTHORS: **Angad Jolly, PhD,** and **Joseph S. Kass, MD, JD, FAAN**

BASIC INFORMATION

DEFINITION

Anthrax is an acute infectious disease caused by the spore-forming bacterium *Bacillus anthracis.*

ICD-10CM CODES

A22.0	Cutaneous anthrax
A22.1	Pulmonary anthrax
A22.2	Gastrointestinal anthrax
A22.7	Anthrax sepsis

EPIDEMIOLOGY & DEMOGRAPHICS

- Anthrax most commonly occurs in hoofed animals and can only incidentally infect human beings who come in contact with infected animals or animal products. Between 20,000 and 100,000 cases of cutaneous anthrax occur worldwide annually. Twenty-three cases of anthrax were reported to the CDC from 1972 through 2000.
- Until the bioterrorism attack in 2001, most cases of anthrax occurred in industrial environments (contaminated raw materials used in manufacturing process) or in agriculture.
- There were 22 anthrax cases with five deaths (all inhalational) after a 2001 attack in which anthrax spores were sent through U.S. mail (Fig. E1).
- Traditionally, there are three major anthrax syndromes: cutaneous, inhalational, and gastrointestinal anthrax. A fourth type, injectional anthrax, was recognized after the 2009 to 2010 European outbreak from heroin-injecting drug users. This type of infection has not been reported in the United States.
- Direct person-to-person spread of anthrax is extremely unlikely, if it occurs at all; therefore, there is no need to immunize or treat contacts of persons ill with anthrax, such as household contacts, friends, or coworkers, unless they also were exposed to the same source of infection.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- **Inhalation anthrax** is the most lethal form. It begins with a brief prodrome resembling a viral respiratory illness without rhinorrhea. The incubation period may be as short as 1 day to 6 weeks. Host factors, dose of exposure, and chemoprophylaxis may affect the duration of the incubation period. A severe advanced phase of fever, shock, and respiratory distress follows the prodromal stage. Inhalational anthrax does not cause pneumonia but can progress to acute respiratory distress syndrome. Radiographic evidence of mediastinal widening and pleural and pericardial effusions can also occur. Mortality is higher when infection spreads to the meninges.
- **Cutaneous anthrax** (Fig. E2) is characterized by a skin lesion evolving from a papule, through a vesicular stage, to a depressed black eschar. The incubation period ranges from 1 to 12 days. The lesion is usually painless, but patients also may have fever, malaise, headache, and regional lymphadenopathy. The eschar dries and falls off in 1 to 2 wk with little scarring.
- **Gastrointestinal anthrax** usually follows eating raw or undercooked contaminated meat and can have an incubation period of 1 to 7 days. Disease presentation may be divided into two phases: oropharyngeal and lower gastrointestinal. Involvement of the pharynx is usually characterized by lesions at the base of the tongue, dysphagia, fever, and regional lymphadenopathy. Lower bowel inflammation typically causes nausea, loss of appetite, and fever followed by abdominal pain, hematemesis, and bloody diarrhea. Gastric ulcers may occur and may be associated with hematemesis.
- **Injectional anthrax** may have similar skin lesions present with IV drug users. These may progress rapidly with systemic dissemination. Unlike cutaneous anthrax, the injectional type is not associated with eschar formation on the skin.

ETIOLOGY

The disease is caused by *B. anthracis,* a gram-positive, spore-forming bacillus. It is aerobic, nonmotile, nonhemolytic on sheep's blood agar, and grows readily at a temperature of 37° C, forming large colonies with irregularly tapered outgrowths (a Medusa head appearance). In the host, it appears as single organisms or chains of two or three bacilli (Fig. E3).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inhalation anthrax must be distinguished from influenza-like illness (ILI) and tularemia. Most cases of ILI are associated with nasal congestion and rhinorrhea, which are unusual in inhalation anthrax. Additional distinguishing factors are the usual absence of abnormal chest radiograph in ILI (see the following).

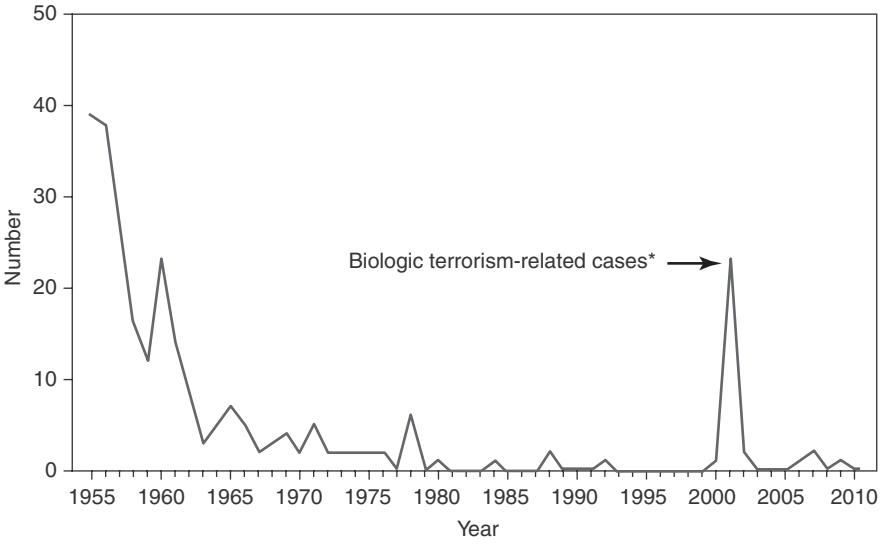

FIG. E1 Anthrax. Number of reported cases, by year—United States, 1955-2010. *One epizootic-associated cutaneous case was reported in 2001 from Texas. (From Centers for Disease Control and Prevention: Summary of notifiable diseases—United States, 2010, *MMWR Morb Mortal Wkly Rep* 59:1-111, 2012.)

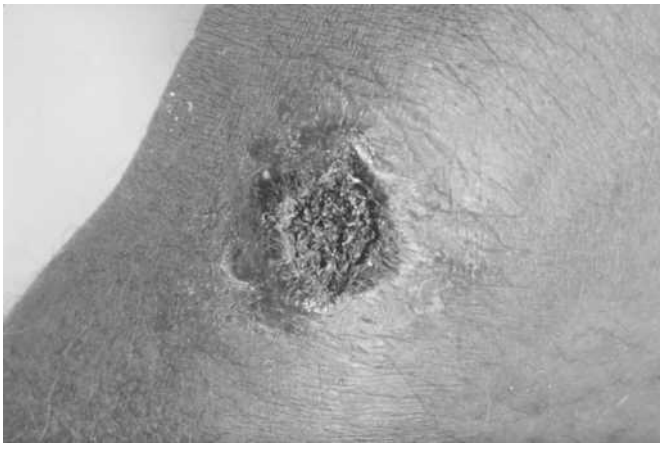

FIG. E2 Cutaneous anthrax lesion on the skin of the forearm caused by the bacterium *Bacillus anthracis.* (From the Centers for Disease Control and Prevention Public Health Image Library. http://phil.cdc.gov/Phil/home.asp.)

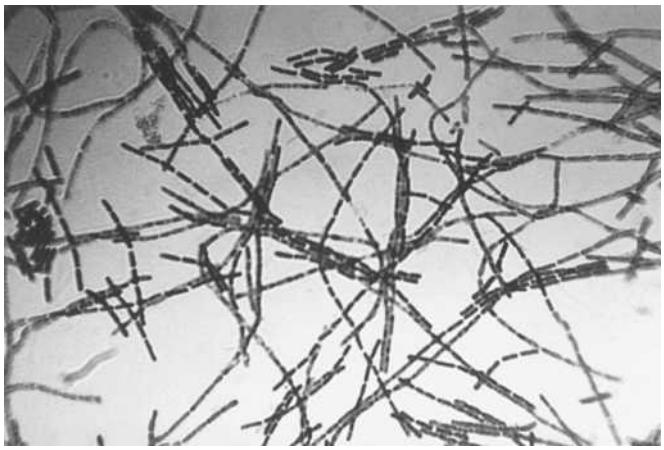

FIG. E3 A photomicrograph of *Bacillus anthracis* bacteria using gram stain technique. Anthrax is diagnosed by isolating *B. anthracis* from the blood, skin lesions, or respiratory secretions or by measuring specific antibodies in the blood of persons with suspected cases. (From the Centers for Disease Control and Prevention Public Health Image Library. http://phil.cdc.gov/Phil/home.asp.)

- Cutaneous anthrax should be distinguished from staphylococcal disease, ecthyma, ecthyma gangrenosum, plague, brown recluse spider bite, and tularemia.
- The differential diagnosis of gastrointestinal anthrax includes viral gastroenteritis, shigellosis, and yersiniosis.

LABORATORY TESTS

- Presumptive identification is based on Gram stain of material from skin lesion, cerebrospinal fluid (CSF), or blood showing encapsulated gram-positive bacilli.
- Confirmatory tests are performed at specialized laboratories. Virulent strains grow on nutrient agar in the presence of 5% CO_2. Susceptibility to lysis by gamma phage and direct fluorescent antibody (DFA) staining of cell-wall polysaccharide antigen are also useful confirmatory tests.
- Nasal swab culture to determine inhalation exposure is of limited diagnostic value. A negative result does not exclude the possibility of exposure. It may be used by public health officials to assist in epidemiologic investigations of exposed persons to evaluate the dispersion of spores.
- Serologic testing by enzyme-linked immunosorbent assay (ELISA) can confirm the diagnosis.
- A skin test (Anthracin test) that detects anthrax cell-mediated immunity is also available in specialized laboratories.
- Depending on disease severity, laboratory studies may also demonstrate hemoconcentration, elevated liver enzymes, anemia, thrombocytopenia, and coagulopathy.

IMAGING STUDIES

Chest radiographs usually reveal mediastinal widening. Additional findings include infiltrates and pleural effusion. An echocardiogram may reveal pericardial effusion.

Rx TREATMENT

NONPHARMACOLOGIC Rx

IV hydration and ventilator support may be necessary with inhalation anthrax.

ACUTE GENERAL Rx

- Uncomplicated cutaneous anthrax can be treated with an oral fluoroquinolone or doxycycline for 7 to 10 days. When inhalation of spores has occurred, the duration should be extended to 60 days.
- CDC recommendations (MMWR 64(4), 2015) for a clinical framework and medical countermeasure use during an anthrax mass-casualty incident are summarized in Figs. E4 through E6 and Boxes E1 through E3.
- If meningitis has not been ruled out, the IV antimicrobial regimen should include a fluoroquinolone plus a bactericidal with good CNS penetration (meropenem) plus a protein synthesis inhibitor (linezolid).
- If meningitis has been ruled out, a two-drug regimen that includes a fluoroquinolone plus linezolid or clindamycin is recommended. The addition of glucocorticoids should be in accordance with the bacterial meningitis protocol.
- Adjunct therapies for inhalation anthrax include the use of toxin-targeting monoclonal antibodies in combination with antibacterial drugs and prophylaxis. Raxibacumab and obiltoxaximab are currently available monoclonal antibodies from the Centers for Disease Control (CDC) and are not available for commercial sale. Drainage of toxin-laden fluids (pleural, pericardial effusions, and ascites) is also recommended.
- Initial postexposure prophylaxis therapy in adults is with ciprofloxacin, 500 mg PO bid, doxycycline 100 mg bid, or levofloxacin 500 mg daily. The total duration of treatment is 60 days. Administration of anthrax vaccine adsorbed (AVA), an inactivated cell-free filtrate of an avirulent strain available from the CDC in a series of three SC injections at 2-wk intervals, is also recommended for known or suspected inhalation exposure to anthrax in adults.
- A single dose of raxibacumab, a human monoclonal antibody directed against protective antigen, has been reported effective in animal studies with symptomatic inhalational anthrax. This can be used when no other option is available.

PROGNOSIS

- Case fatality estimates for inhalation anthrax are extremely high (>90%).
- During the 2001 bioterrorism attacks, the case fatality rate was lower at 45%. The decrease was linked to improvement in critical care management, drainage of effusions, and antimicrobial therapy.
- The case fatality rate for cutaneous anthrax when left untreated is less than 1%.
- The case fatality rate for gastrointestinal anthrax is estimated to be 25% to 60%.
- Even with treatment, the mortality rate for injectional anthrax is 34%.

REFERRAL

Consultation with an infectious disease specialist is recommended in all cases of anthrax. Local and state authorities should also be notified of suspected cases of anthrax.

PEARLS & CONSIDERATIONS

COMMENTS

- Postexposure prophylaxis: If the exposure to *B. anthracis* is confirmed and anthrax vaccine is available, three doses of the vaccine should be given at 0, 2, and 4 wk, and antibiotics should be continued throughout the 4-wk period. If vaccine is not available, antibiotics should be continued for 60 days.
- Preexposure vaccination is limited to groups at risk for repeated exposures to *B. anthracis* spores, such as bioterrorism level B laboratories and workers who will be making repeated entries into known *B. anthracis* spore-contaminated areas.
- The U.S. anthrax vaccine is an inactivated cell-free product licensed to be given in a six-dose series.

BOX E1 Diagnostic Criteria for Sepsis and Severe Sepsis*

Sepsis—documented or suspected infection plus one or more of the following:

General variables
- Fever (>38.3° C)
- Hypothermia (core temperature <36° C)
- Heart rate >90/min or >2 SD above normal value for age
- Tachypnea
- Altered mental status
- Significant edema or positive fluid balance (>20 ml/kg over 24 hr)
- Hyperglycemia (plasma glucose >140 mg/dl or 7.7 mmol/L) in the absence of diabetes

Inflammatory variables
- Leukocytosis (WBC count >12 × $10^3/\mu L$)
- Leukopenia (WBC count <4 × $10^3/\mu L$)
- Normal WBC count with greater than 10% immature forms
- Plasma C-reactive protein >2 SD above normal value
- Plasma procalcitonin >2 SD above normal value

Hemodynamic variables
- Arterial hypotension (SBP <90 mm Hg, MAP <70 mm Hg, or an SBP decrease >40 mm Hg in adults or <2 SD below normal value for age)

Organ dysfunction variables
- Arterial hypoxemia (PaO_2/FiO_2 <300)
- Acute oliguria (urine output <0.5 ml/kg/hr for at least 2 hours despite adequate fluid resuscitation)
- Creatinine increase >0.5 mg/dl or >44.2 μmol/L
- Coagulation abnormalities (INR >1.5 or aPTT >60 s)
- Ileus (absent bowel sounds)
- Thrombocytopenia (platelet count <100 × $10^3/\mu L$)
- Hyperbilirubinemia (plasma total bilirubin >4 mg/dl or >70 μmol/L)

Tissue perfusion variables
- Hyperlactatemia (>1 mmol/L)
- Decreased capillary refill or mottling

Severe sepsis—documented or suspected infection resulting in tissue hypoperfusion or organ dysfunction documented by one or more of the following:
- Sepsis-induced hypotension
- Lactate above upper normal limits of laboratory
- Urine output <0.5 ml/kg/hr for >2 hours despite adequate fluid resuscitation
- Acute lung injury with $PaO2/FiO_2$ <250 in the absence of pneumonia as infection source
- Acute lung injury with $PaO2/FiO_2$ <200 in the presence of pneumonia as infection source
- Creatinine >2.0 mg/dl (176.8 μmol/L)
- Bilirubin >2 mg/dl (34.2 μmol/L)
- Platelet count <100 × $10^3/\mu L$
- Coagulopathy (international normalized ratio >1.5)

*Diagnostic criteria for sepsis in the pediatric population are signs and symptoms of inflammation plus infection with hyperthermia or hypothermia (rectal temperature >38.5° or <35° C), tachycardia (might be absent in hypothermic patients), and at least one of the following indications of altered organ function: altered mental status, hypoxemia, increased serum lactate level, or bounding pulses.
aPTT, Activated partial thromboplastin time; *INR,* international normalized ratio; *MAP,* mean arterial pressure; *SBP,* systolic blood pressure; *SD,* standard deviation; *WBC,* white blood cell.
Adapted with permission from Dellinger RP et al: Surviving sepsis campaign: international guidelines for management of severe sepsis and septic shock: 2012, *Crit Care Med* 41:580-637, 2013; from Centers for Disease Control and Prevention: Clinical framework and medical countermeasure use during an anthrax mass-casualty incident, *MMWR* 64(RR04):1-28, 2015.

BOX E2 Parenteral Antimicrobial Choice for Treatment of Systemic Anthrax in Conventional, Contingency, and Crisis Standards of Care

Conventional setting
- Patients with probable, confirmed, or suspected meningitis should be treated with three recommended antimicrobials with good central nervous system penetration.
- Patients without evidence of meningitis should be treated with a minimum of one bactericidal agent plus one protein synthesis inhibitor.
- Parenteral combination treatment of systemic anthrax should be provided for at least 2 weeks or until the patient is clinically stable, whichever is longer; at that point, the patient may be transitioned to oral monotherapy for prophylaxis against ungerminated spores.

Contingency setting
- Same as conventional setting, except that alternatives to first-line antimicrobial treatment recommendations may be used.

Crisis setting
- If triple antimicrobial therapy is not available, patients with probable, confirmed, or suspected meningitis may be treated with two recommended antimicrobials (one bactericidal agent and one protein synthesis inhibitor, both with good central nervous system penetration).
- Patients without evidence of meningitis:
  1. Should be treated with a bactericidal antimicrobial combined with a protein synthesis inhibitor.
  2. Parenteral therapy may be stopped based on clinical judgment that the patient is clinically stable and improving; at that point, the patient may be transitioned to oral monotherapy for prophylaxis against ungerminated spores.
- Patients with confirmed or suspected meningitis are recommended to receive at least 14 days of antimicrobials and be clinically stable and improving, before considering transition to oral monotherapy for prophylaxis against ungerminated spores.

Centers for Disease Control and Prevention: Clinical framework and medical countermeasure use during an anthrax mass-casualty incident, *MMWR* 64(RR04):1-28, 2015.

BOX E3 Antitoxin Prioritization for Treatment of Systemic Anthrax in Conventional, Contingency, and Crisis Standards of Care

Conventional setting

- An antitoxin should be added to the combination antimicrobial treatment for patients for whom there is a high level of clinical suspicion for systemic anthrax.

Contingency setting

- Patients for whom there is a high level of clinical suspicion of systemic anthrax, with clinical symptoms or signs consistent with any of the general or inflammatory sepsis variables and in whom severe sepsis has not been diagnosed, should receive:
  1. Combination parenteral antimicrobial therapy.
  2. Short-term reevaluation and observation is recommended.
  3. Based on the clinical judgment of the local triage team, an antitoxin may be added to the antimicrobial regimen for patients who do not display rapid clinical improvement or who demonstrate any signs or symptoms of clinical deterioration.
- Patients for whom there is a high level of clinical suspicion for systemic anthrax, with clinical signs or symptoms consistent with severe sepsis or septic shock with a reasonable expectation of survival based on clinical judgment of the local triage team, should receive combination parenteral antimicrobial therapy plus antitoxin without delay.
- Patients with probable, confirmed, or suspected meningitis should receive combination parenteral antimicrobial therapy plus antitoxin without delay.
- Mechanisms should be in place to capture critical care and organ dysfunction measurements among septic anthrax patients, including measurements included in the sequential organ failure assessment (SOFA) score and other objective scoring systems.
- Disease-specific prognostic indicators should be defined based on real-time data and may inform and augment decisions of the local triage team regarding resource allocation.

Crisis setting

- Same as contingency setting.

Centers for Disease Control and Prevention: Clinical framework and medical countermeasure use during an anthrax mass-casualty incident, *MMWR* 64(RR04):1-28, 2015.

Antibody-Mediated Autoimmune Encephalitis

BASIC INFORMATION

DEFINITION

Antibody-mediated autoimmune encephalitis is a neurologic disease causing a spectrum of deficits, including subacute memory loss, changes in cognition, and depressed level of consciousness. Antibodies directed against membrane receptors and ion channel-associated proteins expressed on the surface of neurons in the central nervous system are responsible for these clinical manifestations.

SYNONYMS

Antibody-mediated encephalitis
Autoimmune encephalitis
Autoimmune encephalopathy
Anti-NMDAR encephalitis
Voltage-gated potassium channel antibody syndromes

CD-10CM CODE
G04.81 Other encephalitis and encephalomyelitis

EPIDEMIOLMOGY & DEMOGRAPHICS

INCIDENCE: It is difficult to estimate incidence as testing for encephalitis is relatively new. The most common form is anti-N-methyl-D-asparate receptor (anti-NMDAR) encephalitis. The incidence of anti-NMDAR encephalitis is 0.85 per million children annually. No data about incidence in adults is available.
PEAK INCIDENCE: It is difficult to estimate incidence because testing for these diseases is relatively new. The estimated annual incidence of all types of encephalitis is approximately five to eight cases per 100,000 persons. In nearly 50% of the cases the cause cannot be established.
PREVALENCE: It is difficult to estimate prevalence as testing for disease is relatively new.
PREDOMINANT AGE AND SEX: Anti-NMDAR predominantly affects young women, with a median age at presentation of 21 to 23 yr.
GENETICS: There are no known genetic risk factors for developing autoimmune encephalitis.
RISK FACTORS:

- Prior episode of autoimmune encephalitis, especially if not treated with immunotherapy.
- Tumors (particularly ovarian) have been associated with autoimmune encephalitis.
- Prior episode of herpes simplex virus encephalitis.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Typically presents with subacute (days to a few weeks) deficits of memory and cognition often followed by suppressed level of consciousness. If untreated, patients can progress to coma.
- Psychiatric manifestations are common early in the course of autoimmune encephalitis. These may include psychosis, panic attacks, aggression, inappropriate sexual behaviors, compulsive behaviors, euphoria, or fear, among many others.
- Physical examination can show neuromyotonia, hyperekplexia, psychosis, or dystonia.

ETIOLOGY

One category includes antibodies directed to intracellular antigens, such as anti-Hu. These disorders are strongly associated with cancer and involve T-cell responses targeting neurons. These disorders have a poor prognosis secondary to irreversible neuronal killing. Another category involves autoantibodies to extracellular epitopes of ion channels, receptors, and other associated proteins, such as the NMDA receptor. Cancer-associated autoimmune encephalitis tends to be variable but portends a less severe prognosis due to reversible neuronal damage.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infectious encephalitis (especially viral)
- Metabolic encephalopathy
- Wernicke encephalitis
- Neuroleptic malignant syndrome
- Serotonin syndrome
- Lymphoma
- Carcinomatous meningitis

WORKUP

Diagnostic testing to exclude other causes of encephalitis, including infectious and other autoimmune causes, should occur.

LABORATORY TESTS

Autoantibody testing is important for the diagnosis of autoimmune encephalitis. Tests for autoantibodies to NMDAR, LGI1, Caspr2, AMPAR (GluR1, GluR2 subunits), and GABA-B-R are available. These antibody tests are most sensitive and specific with CSF. CSF findings of leukocyte count, total protein, and the presence of oligoclonal bands (OCBs) can drastically differ among subtypes of autoimmune encephalitis. Serum testing may offer a low false-positive rate and a higher false-negative rate.

IMAGING STUDIES

Brain MRI in patients with NMDAR, AMPAR, LGI1, Caspr2, and GABA-B antibodies may be normal or show increased T2 signal, especially in the medial temporal lobes. Testing with MRI and EEG may also be helpful for excluding other causes.

TREATMENT

NONPHARMACOLOGIC THERAPY

Supportive care, including nutrition, is crucial in these patients.

ACUTE GENERAL Rx

Treatment for suspected autoimmune encephalitis is often begun empirically prior to specific antibody test results. This may include IVIG, plasmapheresis, and/or steroids. IVIG may be given early as it is less likely to worsen infectious encephalitis. If the patient does not respond in 2 wk or is critically ill, second-line therapies (rituximab or cyclophosphamide) should be considered.

CHRONIC Rx

No current chronic suppression is recommended for antibody-mediated autoimmune encephalitis, but relapse can occur and tends to follow a similar clinical course to the initial attack.

COMPLEMENTARY AND ALTERNATIVE MEDICINE

No complementary or alternative medicine is known.

DISPOSITION

Patients require hospitalization during treatment but are often discharged home after resolution of disease process.

REFERRAL

Neurology and rheumatology evaluation may be beneficial to help exclude other causes of encephalitis.

PEARLS & CONSIDERATIONS

COMMENTS

Autoantibody tests may be used to diagnose or exclude particular causes, but these tests are complex, and not every positive result is definite evidence of an autoimmune disorder.

PREVENTION

Cancer screening should be completed for high-risk patients, as tumors can be associated with antibody-mediated autoimmune encephalitis. Known associations are HuD proteins in small cell lung cancer and NMDARs in ovarian teratoma.

PATIENT/FAMILY EDUCATION

The Autoimmune Encephalitis Alliance (https://aealliance.org/) is a resource that can be used by patients and their family for further information and support.

BASIC INFORMATION

DEFINITION

Antiphospholipid antibody syndrome (APS), the most common acquired thrombophilia, is characterized by clinical features of arterial or venous thrombosis and/or pregnancy morbidity *and* the persistence of at least one type of antiphospholipid autoantibody (aPL). aPLs are antibodies directed against anionic phospholipids and phospholipid-binding protein cofactors. These autoantibodies lead to stimulation of procoagulant factors and inhibition of the fibrinolytic system. MTOR pathway upregulation, toll-like receptor signaling, and activation of vascular endothelium, monocytes, neutrophils, platelets, complement, pro-inflammatory cytokines, and various coagulation and fibrinolytic pathway targets have all been shown to play a role in this process.

Three types of aPLs have been characterized:

- Anticardiolipin antibodies (detected in approximately 23% to 44% of patients)
- Lupus anticoagulants (detected in approximately 34% of patients)
- Anti-β2-glycoprotein-I antibodies (detected in approximately 20% of patients)

APS can be primary or secondary to a rheumatic disease, with the most common being systemic lupus erythematosus (SLE). APS can affect all organ systems and includes venous and arterial thrombosis, recurrent fetal losses, and cytopenias, including thrombocytopenia and microangiopathic hemolytic anemia.

SYNONYM

Antiphospholipid syndrome

ICD-10CM CODE
D68.61 Antiphospholipid syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- Up to 5% of healthy individuals without a history of thrombosis have positive aPLs.
- Approximately 10% of patients with a deep venous thrombosis have aPLs.
- Nearly 20% of women under 50 who have a cerebrovascular accident (CVA) test positive for aPLs.
- 10% to 15% of women with recurrent miscarriages have aPLs.
- aPLs without APS can be seen in patients with certain medications, infections, malignancies, and autoimmune conditions.

PREDOMINANT AGE: Young to middle-aged adults

RISK FACTORS:

- Underlying SLE and collagen-vascular diseases; other autoimmune disorders, including rheumatoid arthritis, Sjögren syndrome, Behçet syndrome, primary immune thrombocytopenia (also known as idiopathic thrombocytopenic purpura), AIDS.
- Most individuals are otherwise healthy and have no underlying medical condition.
- Thrombotic risk is increased by the presence of other etiologies of systemic hypercoagulability, including oral contraceptives, pregnancy, smoking, prolonged immobilization, genetic thrombophilia, malignancy, and hyperlipidemia.

PROGNOSIS:

- 91% survival at 10 yr
- 71% success rate in pregnancy with recommended therapies; prematurity and intrauterine growth restriction are common complications

GENETICS: Some APS-positive families exist, and human leukocyte antigen (HLA) studies have suggested associations with HLA DR7, DR4, and Dqw7+Drw53.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

No pathognomonic findings on examination; Table 1 summarizes other features suggesting the presence of antiphospholipid antibodies, including abnormal findings consistent with ischemia or infarction.

- Thrombosis (Fig. E1):
  1. Patients with APS are at risk for both venous and arterial thromboses. Venous thromboses are more common, occurring as the initial manifestation of APS in approximately 30% of APS patients. Of all patients with deep venous thrombosis, approximately 10% have aPL. The most common site for deep vein thrombosis is the calf, but thromboses may also occur in the renal, hepatic, axillary, subclavian, vena cava, and retinal veins. The most common site of arterial thrombosis is the cerebral vessels, followed by the coronary, renal, mesenteric, and bypass arteries. Recurrent thrombosis is common with APS.
- Commonly involved organ systems include:
  1. Central nervous system: Stroke, transient ischemic attack, migraine, multi-infarct dementia, epilepsy, movement disorders, transverse myelopathy, retinal venous or arterial occlusion.
  2. Pulmonary: Pulmonary embolism and infarction, pulmonary hypertension, acute respiratory distress syndrome, diffuse alveolar hemorrhage.
  3. Cardiology: Libman-Sacks endocarditis, intracardiac thrombosis, coronary artery disease, myocardial infarction, valvulopathy, left ventricular diastolic dysfunction.
  4. Gastrointestinal: Abdominal pain, gastrointestinal bleed secondary to ischemia, splenic or pancreatic infarction, hepatic vein thrombosis, Budd-Chiari syndrome.
  5. Renal: Hypertension, renal infarct, renal artery or vein thrombosis, acute renal failure, glomerular damage including membranous nephropathy, minimal change disease, and pauci-immune glomerulonephritis.
  6. Hematology: Thrombocytopenia, hemolytic anemia.
  7. Endocrine: Addison disease secondary to adrenal hemorrhage and, less frequently, thrombosis.
  8. Cutaneous: Livedo reticularis, cutaneous necrosis, skin ulcerations, phlegmasia cerulea dolens, gangrene of digits (Fig. E2).
  9. Obstetric: Recurrent spontaneous abortion, premature delivery, or fetal growth restriction.
- **Catastrophic APS** (CAPS) (Table 2): CAPS is a rapidly progressive multi-organ thrombotic disease. Approximately 1% of APS is CAPS; approximately 45% of CAPS do not present as APS initially. CAPS is associated with a high mortality rate (50%). To make the diagnosis of catastrophic APS, four criteria must be satisfied:
  1. Evidence of involvement of three or more organs, systems, and/or tissues. The most common symptoms are abdominal pain, dyspnea, neurologic symptoms, chest pain, and skin rash.
  2. Development of manifestations simultaneously or in ≤1 wk.
  3. Confirmation by histopathology of small-vessel occlusion in at least one organ or tissue.
  4. Laboratory confirmation of the presence of aPL.

TABLE 1 Other Features Suggesting the Presence of Antiphospholipid Antibodies

Clinical
Livedo reticularis
Thrombocytopenia (usually 50,000-100,000 platelets/mm^3)
Autoimmune hemolytic anemia
Cardiac valve disease (vegetations or thickening)
Multiple sclerosis–like syndrome, chorea, or other myelopathy

From Firestein GS et al: *Kelley's textbook of rheumatology,* ed 9, Philadelphia, 2013, WB Saunders.

ETIOLOGY

- Endothelial cells are activated by aPLs causing upregulation of adhesion and procoagulant molecules such as tissue factor and von Willebrand factor.
- Table 3 and Box 2 summarize proposed pathogenic mechanisms of antiphospholipid syndrome. Mechanisms of pregnancy loss in antiphospholipid syndrome are summarized in Box 3.
- Monocyte activation by aPLs yields expression of inflammatory cytokines and additional tissue factor, contributing to the procoagulant state.
- Neutrophil activation by aPLs via complement is proposed to cause the release of neutrophil extracellular traps leading to increased thrombin.
- aPL binding to glycoprotein 1b and ApoE receptor 2 causes platelet activation and increased platelet adhesion.
- aPL binding decreases activation of antithrombin and protein C, while also reducing the ability of activated protein C to inactivate coagulation factors V and VIII.

TABLE 2 Differential Diagnosis of Catastrophic Antiphospholipid Syndrome (CAPS)

Laboratory Abnormalities	CAPS	TTP	DIC
Microangiopathic hemolytic anemia	–	+	+
Thrombocytopenia	+	+	+
Fibrinogen/FDP	Normal/Normal	Normal/Increased	Decreased/Increased
Anticardiolipin antibody	+	–	–
Lupus anticoagulant	+	–	–

DIC, Disseminated intravascular coagulation; *FDP,* fibrin degradation products; *TTP,* time to progression.

TABLE 3 Proposed Pathogenic Mechanisms of Antiphospholipid Syndrome

I. aPL-mediated promotion of tissue factor expression
  A. Direct injury and subsequent anti-β2 GPI binding on endothelial cells
  B. Signaling via annexin A2/TLR4/apoER2 inducing proadhesive prothrombotic phenotype
  C. Induction of adhesion molecules and tissue factor on endothelial cells and cytokine release

II. Activation of platelets and monocytes by aPL antibodies
  A. Activation of platelets via apoER2′, GPIbα, and/or β2 GPI-platelet factor 4 interaction
  B. Interference of β2 GPI in regulating vWF-mediated platelet adhesion
  C. Activation of monocytes results in increased tissue factor, VEGF, cytokine expression
  D. Activation of monocytes causes mitochondrial dysfunction and oxidative stress

III. Inhibition of endogenous anticoagulant and fibrinolytic mechanisms
  A. Disruption of the annexin A5 anticoagulant shield
  B. Interference with fibrinolysis via annexin A2, β2 GPI cofactor activity, autoactivation of XIIa, direct inhibition of plasmin and increase of PAI-1
  C. Inhibition of the protein C pathway: Decreased activation of protein C, barrier of APC proteolysis of factor Va and VIIIa, prevention of protein C and EPCR binding
  D. Interference with tissue factor pathway inhibitor

IV. aPL-mediated activation of complement
  A. Antibodies against β2 GP–HLA-DR7 complexes on cell surfaces trigger complement-mediated cytotoxicity

V. Direct activation of trophoblasts and endometrial cells by aPL antibodies
  A. Abnormal trophoblast proliferation, migration and invasiveness, increased trophoblast apoptosis, and reduced secretion of HCG and adhesion molecules
  B. Disruption in the differentiation of decidual endometrial cells
  C. Disruption of maternal spiral artery transformation and maturation

VI. Other mechanisms
  A. mTORC pathway–mediated vasculopathy
  B. Release in procoagulant microparticles by endothelial cells and platelets

APC, Activated protein C; aPL, antiphospholipid; apoER2, apolipoprotein E receptor 2; EPCR, endothelial cell protein C receptor; β2 *GPI,* β2-glycoprotein I; *HCG,* human chorionic gonadotropin; *HLA,* human leukocyte antigen; *mTORC,* mammalian target of rapamycin complex; *PAI-1,* plasminogen activator inhibitor 1; *TLR,* Toll-like receptor; *VEGF,* vascular endothelial growth factor; *vWF,* von Willebrand factor.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

- aPL binding to annexin A2 (tissue plasminogen activator receptor) contributes to the prothrombotic state seen in APS.
- The mammalian target of rapamycin complex (mTORC) has been shown to be involved in endothelial activation and in regulating expression of tissue factor and IL-8 in monocytes.
- Toll-like receptors 4 and 7 and triggering of the innate immune system are involved in endothelial activation and the development of the prothrombotic state.
- Autoantibodies against other antigens, such as phosphatidylserine, phosphatidyl ethanolamine, and other complexes have been identified in APS patients, but their clinical significance has yet to be elucidated.

DX DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other hypercoagulable states (inherited or acquired):

- Inherited: ATIII, protein C and protein S deficiencies, factor V Leiden, prothrombin gene mutation
- Acquired: Heparin-induced thrombocytopenia, myeloproliferative syndromes, malignancy
- Alternate causes of recurrent pregnancy loss should also be considered (e.g., anatomic or chromosomal abnormalities)

WORKUP

Diagnostic criteria of APS include at least one clinical criterion and at least one laboratory criterion.

- Clinical (Box 1):
  1. Venous, arterial, or small vessel thrombosis *or*
  2. Morbidity with pregnancy, defined as:
     a. Unexplained fetal death at ≥10 wks' gestation *or*
     b. ≥1 premature births before 34 wks' gestation secondary to eclampsia, preeclampsia, or severe placental insufficiency *or*
     c. ≥3 unexplained spontaneous abortions before 10 wks' gestation.
- Laboratory (see Table 4):
  1. Lupus anticoagulant present in plasma on two or more occasions at least 12 wk apart, *or*
  2. Anticardiolipin antibody, IgG or IgM present in serum or plasma at >40 MPL, GPL, or >99th percentile on two or more occasions at least 12 wk apart, *or*
  3. Anti-β2-glycoprotein-I antibodies present in serum or plasma at >99th percentile on two or more occasions at least 12 wk apart
- Screening tests:
  1. Partial thromboplastin time (PTT): Elevated, activated partial thromboplastin time prolongation indicating either the presence of a clotting factor deficiency, or the presence of an inhibitor such as a lupus anticoagulant.
  2. Mixing study: Elevated. Normal plasma is incubated with the patient's plasma. In cases of clotting factor deficiencies, the PTT will correct. If an inhibitor is present as in the case with APS, the PTT will not correct.
  3. Dilute Russell viper venom time: Elevated. Laboratory clotting requires the addition of phospholipids and calcium to plasma samples. Antiphospholipid antibodies bind the phospholipids in the test tube, thereby preventing clot formation. The addition of Russell viper venom to plasma results in immediate activation of Factor X (common pathway). Therefore, it will not be prolonged in intrinsic or extrinsic factor deficiencies but will be prolonged in the presence of an antiphospholipid antibody.
  4. The Lupus Anticoagulant screen is the addition of Russell viper venom to plasma. In the Lupus Anticoagulant confirmatory testing, massive doses of phospholipids are added to saturate the antiphospholipid antibody, thereby correcting the prolonged PTT.
- Initial testing for presence of aPL:
  1. Anticardiolipin (aCL) ELISA antibodies (IgG or IgM), *or*
  2. Lupus anticoagulant activity found, *or*
  3. Anti-beta2-glycoprotein (anti-β2GPI) ELISA antibodies (IgG or IgM).
- Confirmatory aPL testing (Table 5): Repeat testing after 12 wk is required to confirm the persistence of a positive aCL, anti-β2GPI, or LA test because transient aPL elevations can occur.

LABORATORY TESTS

Diagnostic evaluation of aPLs is indicated in:

- Patient with underlying SLE or collagen-vascular disease with thrombosis.
- Patient with recurrent, familial, or juvenile deep vein thrombosis (DVT) or thrombosis in an unusual location (mesenteric or cerebral).

BOX 1 Preliminary Criteria for Classification of Antiphospholipid Syndrome

Clinical criteria

Vascular thrombosis

One or more clinical events of arterial, venous, or small-vessel thrombosis in any tissue or organ. Thrombosis must be confirmed by Doppler ultrasonography, other imaging, or histopathologic analysis, with the exception of superficial venous thrombosis. The histopathologic study does not have to demonstrate significant evidence of inflammation of the blood vessel.

Pregnancy morbidity

- One or more unexplained deaths of morphologically normal fetuses at 10 or more wk of gestation, with a normal fetal morphology confirmed by ultrasound or direct examination of the fetus.
- One or more premature births of a morphologically normal newborn at 34 wk of gestation or before caused by
  - Severe preeclampsia or eclampsia defined according to current standards, or
  - Recognized placental insufficiency
- Three or more consecutive spontaneous abortions without explanation before 10 wk of gestation, excluding those associated with hormonal or anatomic alterations in the mother or chromosomal alterations inherited from either parent.

Laboratory criteria

The presence of at least one of the following test results:

- Lupus anticoagulant in the plasma on two or more separate occasions within a period of 12 wk, detected according to the guidelines of the International Society of Thrombosis and Haemostasis (Scientific Subcommittee on lupus anticoagulant/phospholipid-dependent antibodies).
- IgG or IgM anticardiolipin antibodies in plasma or serum in medium-high titers (more than 40 GPL or MPL units, respectively) on two or more separate occasions within a period of 12 wk, as measured by standardized ELISA.
- IgG or IgM anti–β_2-glycoprotein I antibodies in the serum or plasma (in titer above the 99th percentile) on two or more separate occasions within a period of 12 wk, as measured by standardized ELISA according to recommended procedures.

ELISA, Enzyme-linked immunosorbent assay; *Ig,* immunoglobulin.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

TABLE 4 Assays Used to Confirm Diagnosis of Antiphospholipid Syndrome

Assay	Methodology
"Criteria" aPL Assays	
aCL	ELISA
Anti-β2-GPI	ELISA
LAC	Clotting/functional assays
"Noncriteria" aPL Assays	
Assays to detect antibodies to other phospholipids (i.e., phosphatidylserine, phosphatidylinositol, phosphatidic acid, phosphatidylglycerol, phosphatidylethanolamine, phosphatidylcholine)	ELISA
Annexin A5 resistance assay	Clotting/mechanistic assay
Assays to detect antibodies to prothrombin or prothrombin/phosphatidylserine	ELISA
Assays to detect antibodies to clotting proteins (i.e., protein C, protein S)	ELISA

aCL, Anticardiolipin; *aPL,* antiphospholipid antibody; *ELISA,* enzyme-linked immunosorbent assay; *β2 GPI,* β2 -glycoprotein I; *LAC,* lupus anticoagulant.
From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.

- One or more unexplained thrombotic events. Do not test those at low risk, e.g., elderly patients with other thrombotic risk factors.
- One or more specific pregnancy events.
- Unexplained thrombocytopenia or microangiopathic hemolytic anemia.
- Patients with an unexplained elevation in PTT, or less commonly, in PT/INR.

Rx TREATMENT

ACUTE Rx

- Initial anticoagulation with heparin or low-molecular-weight heparin (LMWH), before transitioning to a vitamin K antagonist (VKA) such as warfarin, is recommended. DOACs are not recommended due to recent studies which have shown increased risk of recurrent thromboembolism, particularly in patients with high-risk APS (positivity for all three antiphospholipid antibodies) for patients on rivaroxaban compared to warfarin.
- Standard intensity (INR 2.0 to 3.0) anticoagulation with warfarin is preferred in venous thrombosis, as prior randomized trials failed to show a decrease in recurrent thromboses with high-intensity anticoagulation (INR 3.0 to 4.0). Task-force reports have not reached a consensus regarding intensity of anticoagulation in secondary thromboprophylaxis of arterial events.
- Unfractionated heparin (UFH) is preferred if quick reversibility is needed.

PRIMARY PREVENTION

- Although other cardiovascular risk factors, such as hypertension and hyperlipidemia, should be controlled, aspirin use for primary prevention remains controversial.
- Adding low-dose warfarin to aspirin for primary prevention seems to confer no benefit.
- Hydroxychloroquine may be useful in those patients with SLE and aPL; it has been shown to reduce the incidence of thrombotic complications in this population.
- Modifiable risk factors for thrombosis, such as smoking and immobility, should also be addressed when possible.
- For pregnant women with a positive test for aPL antibodies without a history of DVT or pregnancy morbidity, decision to treat with low-dose subcutaneous UFH or LMWH and/or low-dose aspirin, or to manage with surveillance should be made on an individual basis as there is no clear consensus data.

SECONDARY PREVENTION

- For men and nonpregnant women, long-term anticoagulation with warfarin, or with UFH or LMWH if warfarin is contraindicated, should be used.
- Modifiable risk factors for thrombosis should be reduced when possible.
- For pregnant women with previously diagnosed APS:
  1. Warfarin should be discontinued before pregnancy due to its teratogenic effects.
  2. For women with APS without prior thrombosis but with pregnancy morbidities of either unexplained fetal death at ≥10 wks' gestation or ≥3 unexplained spontaneous abortions before 10 wks' gestation, aspirin 81 mg in combination with subcutaneous UFH or LMWH is recommended to improve pregnancy outcomes.
  3. For women with APS without prior thrombosis but with pregnancy morbidity of ≥1 premature births before 34 wks' gestation secondary to eclampsia, preeclampsia, or severe placental insufficiency, aspirin 81 mg is recommended to improve pregnancy outcomes.

TABLE 5 Current Assays Used to Confirm the Diagnosis of Antiphospholipid Syndrome

Assay	Method
Criteria aPL assays	
Anticardiolipin	ELISA
Anti–β_2-glycoprotein I	ELISA
Lupus anticoagulant	Clotting or functional assays
Noncriteria aPL assays	
Assays to detect antibodies to other phospholipids (e.g., phosphatidylserine, phosphatidylinositol, phosphatidic acid, phosphatidylglycerol, phosphatidylethanolamine, phosphatidylcholine)	ELISA
Annexin A5 resistance assay	Clotting or mechanistic assay
Assays to detect antibodies to prothrombin or prothrombin/phosphatidylserine	ELISA
Assays to detect antibodies to clotting proteins (e.g., protein C, protein S)	ELISA

aPL, Antiphospholipid antibody; *ELISA,* enzyme-linked immunosorbent assay.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

4. For pregnant women with APS and prior thrombosis, aspirin in combination with subcutaneous UFH or LMWH should be used.
5. Pregnant patients taking LMWH should be transitioned to unfractionated heparin before delivery for ease of reversibility.
6. Hypertension and hyperlipidemia, if present, should be controlled.

FOR CATASTROPHIC ANTIPHOSPHOLIPID ANTIBODY SYNDROME (CAPS)

- The combination of anticoagulation with heparin products, high-dose corticosteroids, and supportive care, including debriding necrotic tissue and treating underlying infections is the mainstay of therapy.
- Patients may be transitioned to oral anticoagulation with warfarin once clinically stable.
- Plasma exchange with or without IVIG has been shown to improve mortality; however, the decision to use IVIG should be made on an individual basis (e.g., avoid in patients in whom anticoagulation has been discontinued).
- Eculizumab (monoclonal antibody against complement protein C5) and rituximab (monoclonal antibody against CD20) have been used successfully in refractory cases.
- Immunosuppressant therapy with cyclophosphamide should be considered in patients with CAPS and SLE as it has been demonstrated to decrease mortality in this group.

CHRONIC Rx

- Anticoagulation with VKAs, such as warfarin, remains the standard of care. The potential role of new oral anticoagulants in APS remains uncertain. Trials involving rivaroxaban did not show non-inferiority to dose adjusted VKAs for thrombotic APS, and in fact showed a non-statistically significant near doubling of the risk for recurrent thrombosis.[1]
- Duration of treatment is unknown and should be determined on an individual basis. However, in the absence of any contraindication to anticoagulation, indefinite therapy is recommended, as the lifelong recurrence rate reached nearly 30% in some studies.
- Immunosuppressive agents such as corticosteroids and cyclophosphamide have not been shown to be effective for chronic treatment of APS.
- Limited data suggest that hydroxychloroquine may be effective in patients with APS and SLE, although efficacy in primary APS remains unproven.
- Recurrent thrombosis can occur even in the setting of "therapeutic" anticoagulation, and multiple assays have been studied to monitor the adequacy of anticoagulation in APS.
- In cases of recurrent thrombosis, hydroxychloroquine and statins (antiinflammatory and antithrombotic activity) may be considered as adjuvant therapies.
- Table 6 summarizes alternative therapies for antiphospholipid syndrome.

[1]Ordi-Ros J et al: Rivaroxaban versus vitamin K antagonist in antiphospholipid syndrome: a randomized noninferiority trial, *Ann Intern Med* 171(10):685-694, 2019.

DISPOSITION

- APS patients have a 20% to 70% risk for recurrent thrombosis. Positivity in more than one aPL assay is associated with increased thrombotic risk.
- Initial arterial thrombosis tends to be followed by arterial events, and initial venous thrombosis tends to be followed by venous events.
- Incidence of developing catastrophic APS is approximately 1.0% among APS patients.

REFERRAL

Referrals to hematology, rheumatology, and/or obstetric medicine should be placed when diagnosis is made.

PEARLS & CONSIDERATIONS

COMMENTS

- Cerebral features of SLE may be more related to thrombosis than inflammation and may respond better to anticoagulants than immunosuppression.
- False-positive lupus anticoagulant (LAC) tests have been reported in patients taking direct oral anticoagulants and heparin. For this reason, thrombophilia testing should be delayed until 2 to 4 wk after completion of anticoagulation.

PREVENTION

Prophylaxis for asymptomatic patients with positive aPL tests without previous thrombosis:

- No routine prophylaxis is recommended.
- Questionable whether low-dose aspirin is effective.
- Antithrombotic prophylaxis for major surgery, prolonged immobilization, and pregnancy is appropriate.
- Avoid combination oral contraceptive pills in women with positive aPL tests.

Anxiety (Generalized Anxiety Disorder) PTG

BASIC INFORMATION

DEFINITION

Generalized anxiety disorder (GAD) is most likely to present in combination with other psychiatric and medical conditions. Individuals with GAD commonly present with excessive and disproportionately high levels of anxiety, fear, or worry for most days over at least a 6-mo period in a number of areas. The worrying must be greater than would be expected given the situation, and it must cause significant interference in functioning. The subjective anxiety must be accompanied by at least three somatic symptoms in adults and one in children (e.g., restlessness, irritability, sleep disturbance, muscle tension, difficulty concentrating, or fatigue). GAD cannot be diagnosed if it occurs only in the context of an active mood disorder, such as depression, or if the anxiety is better explained by another active anxiety disorder, such as PTSD or panic disorder.

SYNONYMS

Anxiety neurosis (former name for a subset of anxiety disorders)
Chronic anxiety
GAD

ICD-10CM CODE
F41.1 Generalized anxiety disorder300.02

DSM-5 CODE
300.02

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 6% to 9% per yr in adult primary care clinics; 1-yr incident rate per 100 persons/yr of 1.12

PEAK INCIDENCE: Peak incidence tends to occur later relative to other anxiety disorders, such as phobias; cumulative incidence of 4.3% by age 34 in a German community sample.

PREVALENCE (IN U.S.): In general population: Lifetime morbid risk of 9%; 12-month prevalence of 2.9%; lifetime prevalence in the National Comorbidity Survey-Replication was 5.7%.

- In primary care setting: 3% (the most common anxiety disorder in this setting)

PREDOMINANT SEX: Women are more frequently affected (2:1 ratio) but may present for treatment less often (3:2 female:male).

PREDOMINANT AGE:

- 30% report onset before age 11
- 50% have onset before age 18
- Median age of onset: 30 yr

GENETICS: Concordance rates in dizygotic twins and monozygotic twins are not different (0% to 5%)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Report of being "anxious" all of their lives
- Excessive worry, usually regarding family, finances, work, or health
- Sleep disturbance, particularly early insomnia
- Muscle tension (typically in the muscles of neck and shoulders) or headache
- Difficulty concentrating
- Daytime fatigue
- Gastrointestinal symptoms compatible with irritable bowel syndrome (one third of patients)
- Physical symptoms are the usual reason for seeking medical attention
- Comorbid psychiatric illness (e.g., dysthymia or major depression) and substance abuse (e.g., alcohol abuse) are frequent

ETIOLOGY

- Hypotheses include models based on neurotransmitters (catecholamines, indolamines) and developmental psychology (e.g., behavioral inhibition, neuroticism, and harm avoidance)
- Prevalence increased with a family history, increase in stress, history of physical or emotional trauma, and medical illness

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Wide range of psychiatric and medical conditions:
  1. Cardiovascular and pulmonary disease, such as cardiac arrhythmias or COPD
  2. Hyperthyroidism, hypoglycemia
  3. Substance abuse (e.g., cocaine, amphetamines, and PCP) or withdrawal (e.g., alcohol or benzodiazepines)
  4. Other anxiety disorders (e.g., social anxiety disorder), mood disorder
  5. Intrusive thoughts in obsessive-compulsive disorder or illness anxiety disorder

WORKUP

- Screening tests may enhance detection. A screening tool often used in primary care is the GAD-2. It asks, "During the past month, have you been bothered a lot by: (1) Nerves or feeling anxious or on edge? (2) Worrying about a lot of different things?" The response to each question is given a score of 0 (not at all), 1 (several days), 2 (more than half of the days), 3 (nearly every day). A score of ≥3 has a sensitivity of 86% and a specificity of 83% for detecting GAD. A simple 7-item in-office case finding instrument, the GAD-7, includes additional questions to assess symptom severity and can be used to monitor symptoms.
- Physical examination: Additional laboratory and radiologic workup depending on presenting symptoms.
- Iatrogenic cause should be suspected if anxiety follows recent changes in medication.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Cognitive-behavioral therapy
- Acceptance and commitment therapy
- Relaxation training and meditative approaches
- Biofeedback
- Psychodynamic psychotherapy

PHARMACOLOGIC THERAPY

- Selective serotonin reuptake inhibitors (SSRIs) or serotonin-norepinephrine reuptake inhibitors (SNRIs)
- Azapirones (e.g., buspirone)
- Benzodiazepines (less favored)

ACUTE GENERAL Rx

- Acute treatment is rarely indicated because GAD is a chronic condition.
- If patients are in acute distress, the possibility of another cause, including another anxiety disorder such as panic disorder, should be considered.
- Caution in prescribing benzodiazepines because of the propensity for misuse and dependence. If used, the patient should be educated about the options and the risks.

CHRONIC Rx

- SSRIs and SNRIs (e.g., venlafaxine and duloxetine) are effective typical first-line treatment. Particularly useful if comorbid depression present.
- Buspirone can be effective with minimal potential for tolerance or abuse. May be less effective in patients with previous benzodiazepine exposure and may require a high-dose titration.
- Benzodiazepines can be effective under close supervision; however, they have fallen out of favor as a first-line treatment given their potential for functional impairment, abuse, and dependence.
- Sedating antidepressants, such as mirtazapine, may also be useful for initial insomnia secondary to anxious ruminations.

DISPOSITION

- GAD is chronic with periodic exacerbations.
- Treatment is given to reduce level of symptoms and improve functioning. Suicide risk is higher than in the general population.

REFERRAL

- For refractory symptoms
- For comorbid psychiatric conditions

PEARLS & CONSIDERATIONS

Since GAD is a risk factor for major depression, screening and early intervention for GAD (especially in women) may sometimes be helpful in reducing vulnerability to a mood disorder later in life.

Aortic Coarctation

BASIC INFORMATION

DEFINITION

Coarctation of the aorta is a narrowing of the aorta that occurs near the ligamentum arteriosum just distal to the origin of the left subclavian artery. It causes an outflow obstruction proximal to the site of the stenosis, which leads to left ventricular pressure overload, hypertrophy, and potentially heart failure. The stenosis can be discrete or long and may have collateral vessels. It is commonly associated with other cardiac abnormalities such as a bicuspid aortic valve, patent ductus arteriosus, or ventricular septal defect.

SYNONYMS

Postductal coarctation of the aorta
Preductal coarctation of the aorta
Congenital hypoplasia of aortic arch
Coarctation of the aorta

ICD-10CM CODE
Q25.1 Aortic coarctation

EPIDEMIOLOGY & DEMOGRAPHICS

Aortic coarctation has a prevalence of approximately 4 per 10,000 live births and accounts for 4% to 6% of all congenital heart defects. It affects predominantly males, with a male to female ratio of 1.5:1.

GENETICS: Although most cases are sporadic and no specific genetic mutations have been identified, there have been case reports of coarctation occurring in families. Its association with a number of other conditions, such as Williams-Beuren and Sturge-Weber syndromes, also suggests a genetic predisposition. Most notably, up to 30% of patients with Turner syndrome also have coarctation of the aorta, and 5% to 15% of girls with coarctation have Turner syndrome.

RISK FACTORS: The cause for aortic coarctation among most patients is unknown. Genetic mutation and environmental causes are possibilities. It also can be acquired through inflammatory conditions such as Takayasu arteritis or severe atherosclerosis.

CLINICAL PRESENTATION & PHYSICAL FINDINGS

- Clinical presentation:
  1. The clinical manifestations of coarctation of the aorta depend on the age of discovery, severity of the aortic narrowing, and adequacy of collateral circulation.
  2. Neonates with severe coarctation may present with heart failure and/or shock when the ductus arteriosus closes. Neonates without severe aortic coarctation or with a persistent patent ductus arteriosus may be asymptomatic. Heart failure rarely occurs beyond the neonatal period.
  3. Beyond infancy, most patients are asymptomatic. Symptoms arise from severe hypertension, which may lead to epistaxis, headache, heart failure symptoms, or aortic dissection. Claudication of the lower extremities may also occur with physical exertion.
- Physical exam findings:
  1. "Brachial-femoral" delay characterized by diminished or delayed femoral pulses compared to the brachial pulses
  2. Upper extremity systolic hypertension
  3. Low or unobtainable blood pressure in the lower extremities
  4. Systolic ejection murmur at the left upper sternal border and left subscapular region
  5. A continuous murmur heard best posteriorly over the thoracic spine may be heard if there are large collaterals
  6. Systolic murmurs may be heard if there are coexisting cardiac defects (i.e., systolic ejection murmur with bicuspid aortic valve)

ETIOLOGY

- The exact pathogenesis is unknown. The two main theories for potential mechanisms are reduced antegrade intrauterine flow leading to underdevelopment of the fetal aortic arch and abnormal extension of tissue from the ductus arteriosus into the wall of the fetal thoracic aorta.
- In aortic coarctation, the arterial wall of the aorta has several pathologic abnormalities. There are cystic medial necrosis, increased stiffness and less distensibility, and increased collagen and less smooth muscle mass in the prestenotic segment.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hypoplastic left heart syndrome
- Interrupted aortic arch
- Pseudocoarctation
- Left ventricular outflow tract obstruction, including subaortic and supravalvular aortic stenosis
- Prior surgical ligation
- Critical aortic valve stenosis
- Obstructive peripheral arterial disease
- Aortic dissection

WORKUP

- Bilateral arm and leg blood pressures should be measured to search for a differential pressure.
- For patients with suspected aortic coarctation, the physical exam should include simultaneous palpation of the brachial and femoral pulses to assess for "brachial-femoral delay," which is characteristic of significant aortic coarctation.
- An electrocardiogram may show left ventricular hypertrophy, ST-T wave abnormalities, and RV conduction delay.
- Transthoracic echocardiogram, including suprasternal notch acoustic windows, should be performed.
- Every patient with coarctation should have at least one cardiovascular MRI or CT scan for a complete evaluation of the thoracic aorta and intracranial vessels.
- Cardiac catheterization is indicated when associated coronary artery disease is suspected or for therapeutic intervention of the coarctation.

LABORATORY TESTS

No specific laboratory tests are needed for coarctation of the aorta.

IMAGING STUDIES

- Box E1 summarizes important findings in the imaging evaluation of coarctation of the aorta. Anomalies associated with aortic coarctation are described in Box E2.
- Chest x-ray (Fig. E1):
  1. Posterior rib notching of ribs 3 to 8 is due to bony erosion by large collateral arteries.
  2. The "3" sign is formed by indentation of the aortic wall at the site of the coarctation with pre- and postcoarctation dilation.
- Echocardiography:
  1. Generally, echocardiography can establish the diagnosis and severity of coarctation of the aorta, but it is less useful for postoperative patients or for adult patients who may have less favorable acoustic windows compared with children.
  2. Aortic narrowing is visualized in the suprasternal notch view.
  3. Color flow imaging and pulsed Doppler localize the area of coarctation.
  4. Continuous wave Doppler estimates the severity of coarctation. The presence of collaterals may diminish the gradient across the coarctation; the gradient may be less severe than expected for the degree of the obstruction.
  5. Associated cardiac defects, chamber sizes, and left ventricular function can be evaluated.
- Magnetic resonance imaging and computed tomography:
  1. Per the ACC/AHA adult congenital heart disease guidelines, every adult patient with coarctation should have at least one cardiovascular MRI (Fig. E2, Fig. E3) or CT (Fig. E4) or a complete evaluation of the thoracic aorta.
  2. The modalities have very high diagnostic accuracy (>95%) in detecting coarctation of the aorta and its associated abnormalities.
  3. Both provide a large field of view and allow simultaneous visualization of the ascending aorta, aortic arch, descending aorta, aortic valve, and collaterals.
  4. CT and MRI are indicated for serial follow up imaging after surgical repair to assess for aortic dilatation or aneurysm formation.
  5. MRI is preferred to CT to decrease the lifetime exposure to radiation.
- Cardiac catheterization:
  1. Cardiac catheterization (Fig. E5) may be used to assess the peak gradient across the coarctation but is usually performed in conjunction with a therapeutic intervention (balloon angioplasty or stent placement).

TREATMENT

ACUTE GENERAL Rx

- Infants with critical coarctation are at risk for heart failure and death once the ductus arteriosus closes. Treatments include:
  1. Continuous intravenous infusion of prostaglandin E1 to keep the ductus arteriosus patent

BOX E1 Imaging Evaluation of Coarctation of the Aorta

Patency of the Ductus Arteriosus
Closed
Patent
Flow from aorta to pulmonary artery (typically postductal coarctation)
Flow from pulmonary artery to aorta (preductal coarctation or pulmonary hypertension)

Collateral Pathways
Scarce (typical of patients under 2 yr of age)
Abundant
Bridging the coarctated segment
Internal mammary to intercostal to distal aorta
Circumscapular pathways to distal aorta

Other Arch Anomalies and Stenoses
Arch interruption
Double aortic arch with stenosis in either or both arches
Coarctation proximal to left subclavian artery
Takayasu aortitis, rubella, Williams syndrome, neurofibromatosis, mucopolysaccharidosis, and other causes of stenoses not in the aortic isthmus

Subclavian Artery Anomalies
Atresia or stenosis of the left subclavian artery
Aberrant retroesophageal right subclavian artery
Proximal to the coarctation
Distal to the coarctation
Origin of both subclavian arteries distal to the coarctation

Associated Lesions
Cardiac, such as ventricular septal defect or bicuspid aortic valve
Aneurysms:
In aorta adjacent to coarctation
In the ductus
In the intercostal arteries
In the circle of Willis

Boxt LM, Abbara S: *Cardiac imaging: the requisites,* ed 4, Philadelphia, 2016, Elsevier.

BOX E2 Anomalies Associated with Aortic Coarctation

Common
Bicuspid aortic valve with stenosis and regurgitation
Patent ductus arteriosus
Ventricular septal defects
Turner syndrome

Rare:
Transposition of the great arteries
Double-outlet right ventricle
Shone syndrome (parachute mitral valve, supramitral ring, aortic valve stenosis, and aortic coarctation)

Boxt LM, Abbara S: *Cardiac imaging: the requisites,* ed 4, Philadelphia, 2016, Elsevier.

2. Dopamine and/or dobutamine to increase contractility for those with heart failure
3. Surgical repair once the patient is stabilized

CHRONIC Rx

- Systemic hypertension should be treated with angiotensin-converting enzyme inhibitors, angiotensin-receptor blockers, or beta-blockers.
- All patients with aortic coarctation should have long-term follow up with a congenital heart disease specialist.
- After repair, a CT or MRI of the repair site should be obtained at 1 yr postoperatively and then every 5 yr or less depending on anatomy to detect long-term complications.

NONPHARMACOLOGIC THERAPY

Aortic coarctation can be repaired surgically or percutaneously by balloon angioplasty and/or stent placement. The choice of intervention is made on an individual basis based on aortic morphology and should be determined by a multidisciplinary team including cardiologists, interventionalists, and cardiac surgeons who are experienced in treating patients with congenital heart disease.

- Repair should be performed in infancy or early childhood to prevent the common complications of unrepaired coarctation, including systemic hypertension, accelerated coronary artery disease, stroke, heart failure, and aortic dissection.
- The indications for intervention according to the ACC/AHA guidelines for the management of adults with congenital heart disease are:
  1. Peak-to-peak coarctation gradient ≥20 mm Hg (Level of evidence C).
  2. Peak-to-peak coarctation gradient <20 mm Hg in the presence of anatomic imaging evidence of significant coarctation (≥50% stenosis) with radiologic evidence of significant collateral flow (Level of evidence C).
- Surgery:
  1. Options include resection of coarctation and end-to-end anastomosis, a bypass graft across the area of coarctation, subclavian flap aortoplasty in long-segment coarctation, and prosthetic patch aortoplasty.
  2. Surgery compared with balloon angioplasty has been shown to be equally effective in reducing the peak systolic pressure gradient early after intervention.
  3. Surgery is indicated in the presence of a long re-coarctation segment, aortic aneurysm or pseudoaneurysm, or aortic arch hypoplasia.
- Balloon angioplasty and/or stent placement:
  1. Balloon angioplasty is the preferred intervention for patients with recurrent, discrete stenosis.
  2. Stent placement is not recommended in children <25 kg due to potential vascular complications from the large sheath size and the need for repeated interventions to expand the stent as they grow.
  3. Potential complications of percutaneous intervention include immediate residual pressure gradients, re-coarctation, aneurysm formation, dissection, and femoral artery complications.

COARCTATION AND PREGNANCY

Women with coarctation should receive prepregnancy counseling with input from an adult congenital heart disease specialist to determine maternal cardiac, obstetric, and fetal risks. Women with severe coarctation have an extremely high risk of maternal mortality and severe morbidity, and if pregnant, the option of pregnancy termination should be discussed.

REFERRAL

- All patients with coarctation of the aorta, with or without repair, should be referred to a congenital heart specialist.
- Intervention should involve a multidisciplinary team of cardiologists, interventionalists, and surgeons at an adult congenital heart disease center.

PEARLS & CONSIDERATIONS

COMMENTS

- Aortic coarctation is most commonly found distal to the origin of the left subclavian artery.
- The pathognomonic physical exam finding of aortic coarctation is the brachio-femoral delay.
- Systemic hypertension is the most common long-term complication of untreated aortic coarctation, but it is also associated with accelerated coronary artery disease, stroke, aortic dissection, and heart failure.
- An adult congenital heart disease specialist should monitor all patients with aortic coarctation.

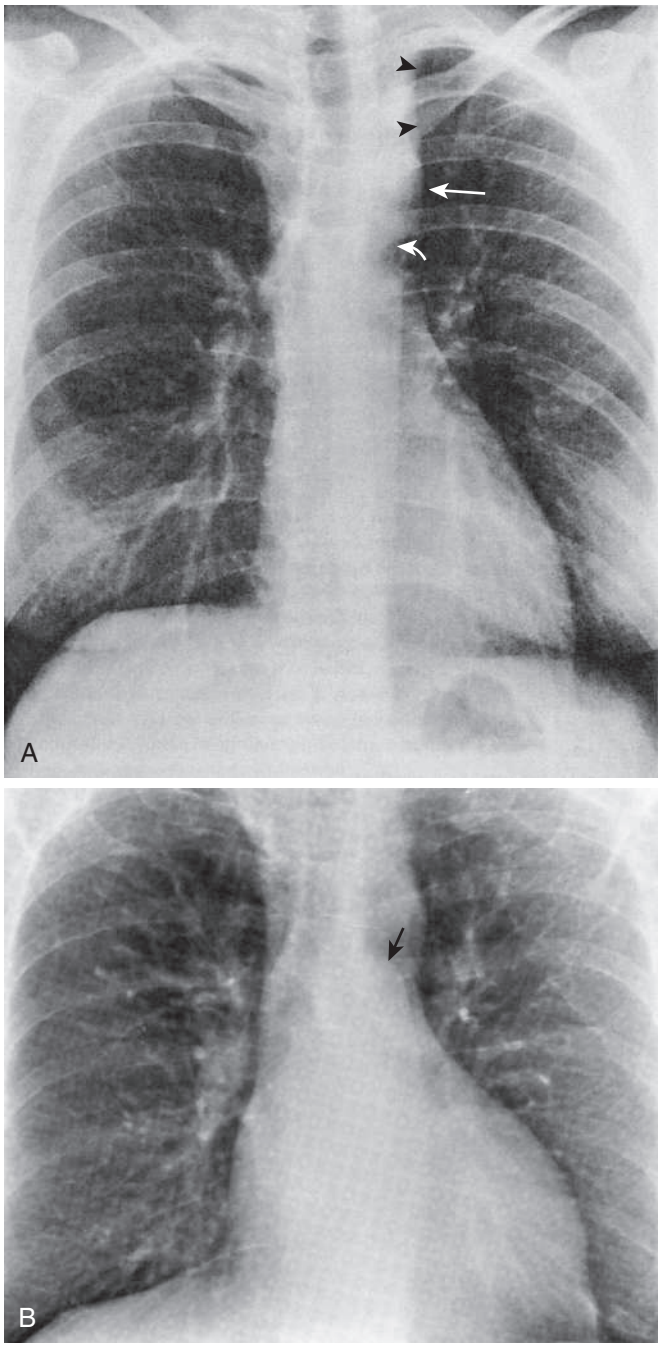

FIG. E1 Coarctation of the aorta. A, Minimal rib notching is present. The arch of the aorta *(straight arrow)* is unusually large, and the left subclavian artery *(arrowheads)* has elongated into the left apex. The site of the coarctation *(curved arrow)* is the deep concavity in the descending aorta. **B,** The para-aortic stripe has a deep indentation *(arrow)* posteriorly behind the pulmonary artery segment. (From Boxt LM, Abbara S: *Cardiac imaging: the requisites*, ed 4, Philadelphia, 2016, Elsevier.)

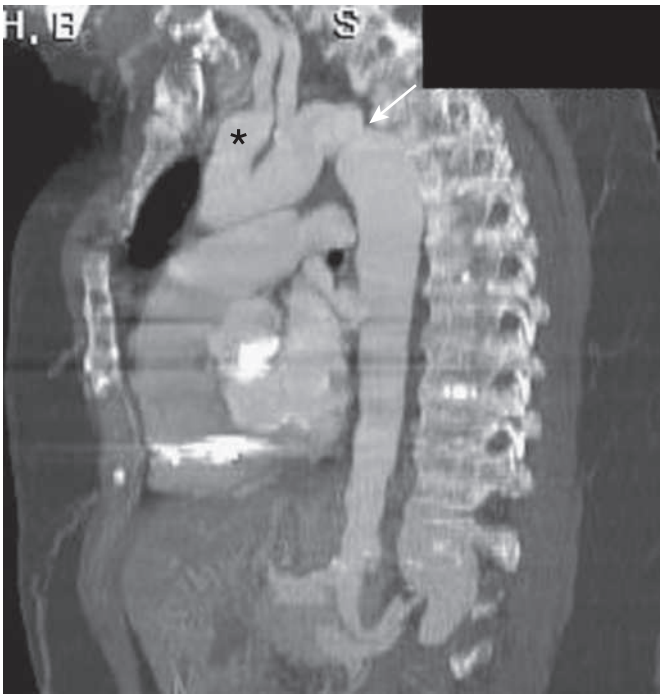

FIG. E2 Coarctation of the aorta. Reformatted computed tomography angiography of the thoracic and abdominal aorta demonstrating a coarctation *(arrow)* of the proximal thoracic aorta with prominent poststenotic dilatation. There is also aneurysmal enlargement of the brachiocephalic artery (*). (Courtesy Ruchira Garg, MD. From Boxt LM, Abbara S: *Cardiac imaging: the requisites*, ed 4, Philadelphia, 2016, Elsevier.)

FIG. E3 Coarctation of the aorta. A gadolinium-enhanced 3D surface rendering of mild coarctation *(arrow)* with some tortuosity of the isthmus. There is no blood pressure gradient across this lesion at rest. (Courtesy Ruchira Garg, MD. From Boxt LM, Abbara S: *Cardiac imaging: the requisites*, ed 4, Philadelphia, 2016, Elsevier.)

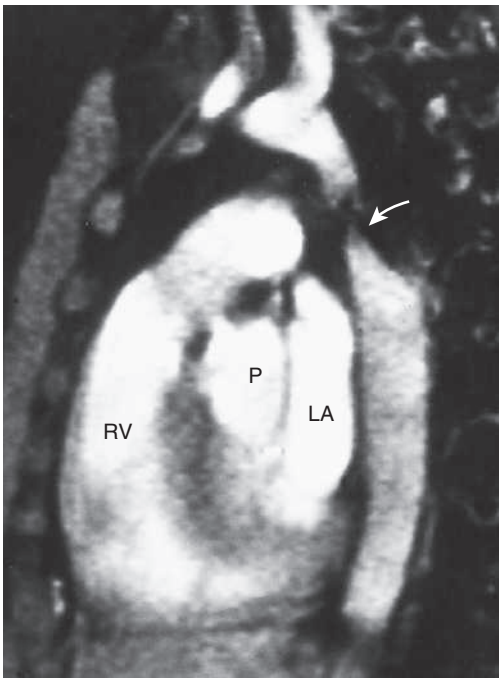

FIG. E4 Gradient echo image of an aortic coarctation. In the sagittal plane, which contains the right ventricle *(RV),* left pulmonary artery *(P),* and left atrium *(LA),* the aortic isthmus has a long stenosis *(curved arrow)* beginning distal to the left subclavian artery. (From Boxt LM, Abbara S: *Cardiac imaging: the requisites*, ed 4, Philadelphia, 2016, Elsevier.)

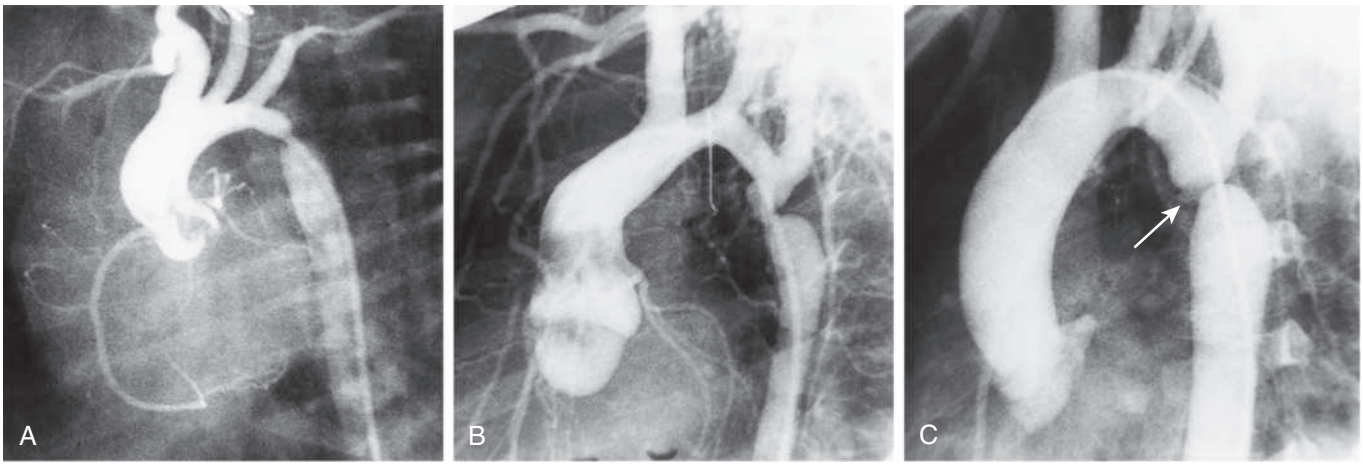

FIG. E5 Coarctation of the aorta. Aortography of three variations of aortic coarctation filmed in the left anterior oblique projection. **A,** Aortic valve stenosis is indicated by the domed leaflets of the bicuspid valve and the poststenotic dilatation of the ascending aorta. The transverse arch is frequently hypoplastic before the coarctation. **B,** The bicuspid aortic valve is oriented in an anteroposterior direction. There is pronounced poststenotic dilatation after the coarctation. Large internal mammary arteries and bridging mediastinal vessels are visible. **C,** The transverse arch has normal size. A small diverticulum *(arrow)* represents the obliterated ductus arteriosus. (From Boxt LM, Abbara S: *Cardiac imaging: the requisites*, ed 4, Philadelphia, 2016, Elsevier.)

BASIC INFORMATION

DEFINITION

Aortic dissection is part of a spectrum of aortic pathologies (acute aortic syndromes) that includes intramural hematomas and penetrating atherosclerotic ulcers. Aortic dissection occurs when blood passes through an intimal tear, separating the intima from the medial layers and creating a false lumen. Intramural hematoma (IMH) occurs when the vasa vasorum ruptures within the medial wall. IMH does not involve an intimal tearing unless a dissection develops. Seventeen percent of IMH will transform into aortic dissection. Penetrating atherosclerotic ulcers, which occur in the setting of extensive aortic atherosclerosis and hypertension, destroy the aortic intima and dissect into the aortic media. Rupture of atherosclerotic plaques with subsequent blood entry into the median wall forms a pseudoaneurysm. Fig. 1 illustrates acute aortic syndromes.

CLASSIFICATION

Aortic dissection is generally classified according to anatomic location (Fig. 2). Table 1 summarizes classification schemes of acute aortic dissection.

- Stanford (more commonly used classification system): Type A ascending aorta (proximal), type B descending aorta (distal)
- DeBakey: Type I ascending and descending aorta, type II ascending aorta, type III descending aorta
- Aortic dissection can also be classified by acuity of presentation: Hyperacute (<24 hr), acute (2 to 7 days), subacute (8 to 30 days), and chronic (>30 days). The overall survival rate is inversely related to time of presentation, with the highest survival rate in the hyperacute group and the lowest survival rate in the chronic group

SYNONYMS

Dissecting aortic aneurysm
Acute aortic syndrome
AAS

ICD-10CM CODES

I71.00	Dissection of unspecified site of aorta
I71.01	Dissection of thoracic aorta
I71.02	Dissection of abdominal aorta
I71.03	Dissection of thoracoabdominal aorta

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 2.6 to 3.5 per 100,000 person-yr; more frequent in winter as compared to other seasons, although no clear reason has been identified

PREDOMINANT SEX AND AGE: Males (65%) females (35%), ages 60 to 80 yr; mean = 63 yr

RISK FACTORS (TABLE 2):

- Hypertension (found in up to 77% of patients with aortic dissection)
- Atherosclerosis (found in up to 27% of patients with aortic dissection)
- Preexisting aortic aneurysm (found in up to 16% of patients with aortic dissection)
- Age (60 to 80 yr)
- Family history of aortic aneurysms/dissection
- History of cardiac surgery, aortic valve replacement, intraaortic catheterization
- Disorders of collagen (Marfan syndrome, Ehlers-Danlos syndrome)
- Vascular inflammation (giant cell arteritis, Takayasu arteritis, rheumatoid arthritis, syphilitic aortitis)
- Aortic coarctation, bicuspid aortic valve
- Turner syndrome
- Cocaine abuse (usually within 12 hours of last use of cocaine)
- Trauma
- Pregnancy and delivery
- Fluoroquinolone use
- Table 3 summarizes genetically triggered conditions associated with aortic dissection

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Sudden onset of severe sharp, tearing, or ripping chest pain. However, painless dissection occurs in approximately 6.4% of cases
- Anterior chest pain (79% type A, 63% type B)
- Back pain, abdominal pain (43% type A, 64% type B)
- Syncope (19% type A, 3% type B), generally secondary to cardiac tamponade or stroke
- Congestive heart failure (CHF)
- May present with hypertension (28% for type A, 66% in type B dissection), although 25% present with hypotension (systolic blood pressure <100 mm Hg), which can indicate bleeding, cardiac tamponade, or severe aortic regurgitation. Patients presenting with very high systolic blood pressure (>180 mm Hg for type A, >200 mm Hg for type B dissection), as well as in those with systolic blood pressure <=100 mm Hg, have significantly higher in-hospital mortality rates
- Pulse and blood pressure differentials (>20 mm Hg between arms) in 19% to 31% of cases caused by partial compression of subclavian arteries
- Aortic regurgitation in 18% to 50% of cases of proximal dissection, often with diastolic decrescendo murmur
- Myocardial ischemia caused by coronary artery occlusion, most commonly involving the right coronary artery
- Stroke in 5% to 10% of patients (secondary to dissection into or decreased blood flow to the carotids)
- Mesenteric ischemia occurs in 3% to 5% of cases, with external compression, flap prolapse, or involvement of arterial ostia
- Horner syndrome (ptosis, miosis, anhidrosis)
- Vocal cord paralysis or hoarse voice (caused by compression of the left recurrent laryngeal nerve)

ETIOLOGY

Genetics, in addition to other risk factors listed previously, contribute to the development of aortic dissection.

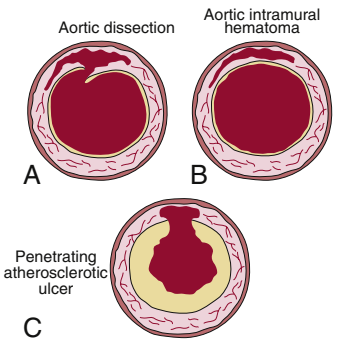

FIG. 1 Acute aortic syndromes. A, Classic aortic dissection. There is a tear in the intima with blood entering the media and a dissecting cleavage plane propagating for variable distances anterograde (and occasionally retrograde) throughout the aortic wall. **B,** Aortic intramural hematoma (IMH). A spontaneous hemorrhage of the vasa vasorum leads to bleeding within the media in the absence of an intimal tear or intimal flap. **C,** Penetrating atherosclerotic aortic ulcer (PAU). An ulcerated aortic plaque ruptures into the media, leading to an outpouching or ulceration in the aortic wall. This may be associated with IMH formation, pseudoaneurysm, or a focal, thick-walled aortic dissection. (From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Known as the great imitator: Pulmonary embolism, acute coronary syndrome, aortic stenosis/insufficiency, nondissecting aneurysm, pericarditis, cholecystitis, peptic ulcer disease, pancreatitis, musculoskeletal pain.
- Consider aortic dissection in patients with unexplained stroke, chest pain, syncope, acute-onset CHF, abdominal pain, back pain, and malperfusion of extremities or internal organs. Acute aortic syndromes may be associated with nonspecific signs and symptoms; a high clinical index of suspicion is necessary to detect the disease early in its course as nearly two thirds of patients under medical care are not diagnosed prior to death.
- In an emergency situation, a rapid yet comprehensive workup is crucial to reduce diagnostic time delay. This should include clinical assessment, laboratory data (D-dimer and troponin), chest x-ray, electrocardiogram (ECG), and aortic imaging in the appropriate patient.

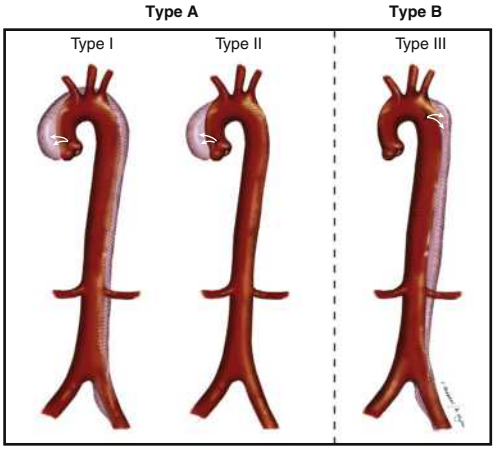

FIG. 2 Classification schemes of acute aortic dissection. (From Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.)

TABLE 1 Classification Schemes of Acute Aortic Dissection

DeBakey Classification	
Type I	Originates in the ascending aorta and extends at least to the aortic arch and often to the descending aorta (and beyond)
Type II	Originates in the ascending aorta and confined to this segment
Type III	Originates in the descending aorta, usually just distal to the left subclavian artery, and extends distally
Stanford Classification	
Type A	Dissections involving the ascending aorta (with or without extension into the descending aorta)
Type B	Dissections not involving the ascending aorta

From Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.

- The Aortic Dissection Detection Risk Score (ADD-RS) can be a useful tool in diagnosing aortic dissection in the emergency room setting. ADD-RS is based on the presence of one or more of the clinical risk markers outlined in Table 4. A high ADD-RS effectively stratifies the risk for acute aortic dissection (score 0 is low risk, score 1 is intermediate risk, and score ≥2 is high risk). Score 0 has 95.6% certainty in ruling out aortic dissection.
- The addition of D-dimer to ADD-RS may further improve diagnostic performance of each of these when used alone for ruling out acute aortic dissection or other acute aortic syndromes. Among low- to intermediate-risk patients (ADD-RS <2), a negative D-dimer (<500 mg/dl) can rule out aortic dissection with 99.7% certainty. Among high-risk patients (ADD-RS ≥2), D-dimer is not discriminatory and requires conclusive imaging.

WORKUP

ECG: Helpful to rule out MI, although dissection can lead to coronary ischemia.

LABORATORY TESTS

- D-dimer has a high negative predictive value in dissection, but lacks specificity in the setting of acute aortic dissection. However, a negative D-dimer does not rule out intramural hematoma or penetrating aortic ulcer.
- Soluble ST2, a novel biomarker, may have superior diagnostic performance over D-dimer in discriminating acute aortic dissection from other acute chest pain syndromes. At a cutoff level of 34.6 ng/ml, the sensitivity and specificity for acute aortic dissection were 99.1% and 84.9%, respectively.
- Several other biomarkers with different diagnostic windows can be used in the diagnosis of aortic dissection:
  1. Smooth muscle myosin heavy chain protein (released from damaged medial smooth muscle) can be used to detect proximal aortic dissections (91% sensitivity and 93% specificity). Myosin heavy chains will peak within 3 hr of dissection and clear within 24 hr of aortic injury.
  2. CK-BB isoenzyme also peaks within 6 hr of dissection.
  3. Calponin, a smooth muscle troponin counterpart, increases in aortic dissection with a wider diagnostic window when compared to smooth muscle myosin heavy chain and CK-BB.
  4. C-reactive protein, fibrinogen and soluble elastin fragments are under investigation.

IMAGING STUDIES

- Multidetector CT (Fig. E3 and Fig. E4) is considered the gold standard, but its use may be limited in patients with renal failure as it involves the use of intravenous contrast.

TABLE 2 Risk Factors for Aortic Dissection

- Hypertension
- Heritable or genetic thoracic aortic disease and syndromes
  - Marfan syndrome
  - Loeys-Dietz syndrome
  - Familial thoracic aortic aneurysm syndromes
  - Vascular Ehlers-Danlos syndrome
  - Turner syndrome
- Congenital diseases/syndromes
  - Bicuspid aortic valve
  - Coarctation of the aorta
  - Tetralogy of Fallot
- Atherosclerosis
  - Penetrating atherosclerotic ulcer
- Trauma, blunt or iatrogenic
  - Catheter/guidewire
  - Intra-aortic balloon pump
  - Aortic/vascular surgery
  - Motor vehicle accident
  - Coronary artery bypass grafting/aortic valve replacement/TAVR
  - Thoracic endovascular aneurysm repair (TEVAR)
- Cocaine/methamphetamine use
- Inflammatory/infectious diseases
  - Giant cell arteritis
  - Takayasu arteritis
  - Behçet syndrome
  - Aortitis
  - Syphilis
- Pregnancy (with underlying aortopathy)
- Weightlifting (with underlying aortopathy)

TAVR, Transcatheter aortic valve replacement.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

- Transesophageal echocardiography (TEE), multidetector CT, and MRI are all highly sensitive (98% to 100%) and specific (95% to 98%). Test of choice depends on clinical circumstances and hospital availability.
- TEE is study of choice in unstable patients with type A dissection but is operator dependent.
- MRI has high sensitivity and specificity but limited availability; not suitable for unstable patients; contraindicated with noncompatible pacemakers, metal devices.
- With medium or high pretest probability, a second diagnostic test should be done if the first is negative.
- Coronary computed tomographic angiography (CTA) may be an alternative and useful diagnostic study when evaluating for pulmonary embolism, acute coronary syndrome, and aortic dissection.
- Aortography rarely done, as less sensitive than TEE, CT, or MRI.
- Chest radiograph may show widened mediastinum (52% in type A dissections and 39% in type B dissections) and displacement of aortic intimal calcium. It is normal in 29% to 36% of patients with aortic dissection.
- Although the diagnostic sensitivity of transthoracic echocardiography is suboptimal (31% to 55%), it is useful in assessing potential high-risk features or complications, such as pericardial effusion, and making other

TABLE 3 Genetically Triggered Conditions Associated with Aortic Dissection

Marfan syndrome (MFS)	Autosomal dominant disorder of connective tissue caused by *FBN1* mutation; incidence of 1 in ≈5000 individuals; multisystem manifestations, including ectopia lentis; mitral valve prolapse, aortic root aneurysm, aortic dissection; skeletal features (pectus deformities, scoliosis, arachnodactyly, hyperflexibility, tall stature, elongated fingers and toes); dural ectasia; spontaneous pneumothorax
Loeys-Dietz syndrome (LDS)	Autosomal dominant disorder caused by mutations in *TGFBR1* and *TGFBR2*, associated with aneurysms and dissections involving the aorta and branch vessels, often at relatively small diameters and young age; manifestations include craniofacial features (hypertelorism, craniosynostosis, cleft palate, bifid or broad uvula), bluish sclera, arterial tortuosity, velvety and hyperlucent skin, easily visible veins, clubfeet, skeletal abnormalities; phenotypes may vary, including those with more pronounced craniofacial features and those with more cutaneous features; ectopia lentis has not been described in LDS; mutations in *TGFB2* lead to a syndrome with an overlap in clinical features of LDS and MFS
Familial thoracic aortic aneurysm (FTAA) syndromes	Autosomal dominant disorders with variable expression and penetrance leading to thoracic aortic aneurysms (TAAs) and dissections at variable ages in families; *ACTA2* mutations occur in 10%-15% of cases of FTAA and are associated with bicuspid aortic valve (BAV) disease, cerebral aneurysms, livedo reticularis, iris flocculi, PDA, moyamoya, and premature coronary artery disease; gene mutations causing familial thoracic aortic aneurysm and dissection (TAAD) include *ACTA2*, *TGFBR1*, *TGFBR2*, *FBN1*, *MYH11*, *MYLK*, *TGFB2*, *SMAD3*
Vascular Ehlers-Danlos syndrome (vEDS)	Autosomal dominant disorder of collagen synthesis caused by a gene mutation in *COL3A1* leading to rupture and dissection of the aorta (usually the descending and abdominal aorta) and branch vessels; manifestations include flexible digits, hyperlucent skin with visible veins, varicose veins, typical facial appearance, and spontaneous rupture of the uterus or bowel
Bicuspid aortic valve (BAV)	Congenital condition affecting ≈1% of the population, familial in ≈9% of cases; often associated with dilation of the ascending aorta and carries increased risk for aortic dissection; gene mutations include *NOTCH1* and loci at 15q, 18q, 5q, and 13q; may be associated with FTAA
Turner syndrome (TS)	Genetic disorder affecting 1 in 2000 live-born girls and caused by complete or partial loss of the second sex chromosome (XO, Xp); women with TS often have BAV and aortic coarctation; associated with ascending aortic dilation for body size and increased risk for aortic dissection, especially when associated with BAV, hypertension, and coarctation
Aneurysms-osteoarthritis syndrome	Autosomal dominant genetic disorder resulting from mutations in the *SMAD3* gene and associated with premature osteoarthritis, osteochondritis dissecans, skeletal features, aortic aneurysms, branch vessel aneurysms, and arterial tortuosity; overlap with LDS phenotype

From Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.

TABLE 4 Aortic Dissection Detection Risk Score (ADD-RS)

Clinical risk markers*	Score
High-risk condition such as Marfan syndrome, family history of aortic disease, known aortic valve disease, known thoracic aortic aneurysm, or previous aortic manipulation, including cardiac surgery.	1
Pain in the chest, back, or abdomen described as abrupt, of severe intensity, or a ripping/tearing sensation.	1
Physical examination findings of perfusion deficit, including pulse deficit, systolic blood pressure difference, or focal neurologic deficit, or with aortic diastolic murmur and hypotension/shock.	1

*Presence of ≥1 marker within each of these groups is given a score of 1 with a maximum cumulative score of 3 if all three are present.

Modified from Erbel R et al: 2014 ESC guidelines on the diagnosis and treatment of aortic diseases: document covering acute and chronic aortic diseases of the thoracic and abdominal aorta of the adult. The Task Force for the Diagnosis and Treatment of Aortic Diseases of the European Society of Cardiology (ESC), *Eur Heart J* 35:2873-926, 2014; Hiratzka LF et al: 2010 ACCF/AHA/AATS/ACR/ASA/SCA/SCAI/SIR/STS/SVM guidelines for the diagnosis and management of patients with thoracic aortic disease, *Circulation* 121:e266-369, 2010; and Hiratzka et al: Surgery for aortic dilatation in patients with bicuspid aortic valves: a statement of clarification from the American College of Cardiology/American Heart Association Task Force on Clinical Practice Guidelines, *J Am Coll Cardiol* 67:724-31, 2016.

potential diagnoses. A negative transthoracic echocardiography, however, does not exclude aortic dissection.

Rx TREATMENT

- Urgent surgical consultation should be obtained for all thoracic aortic dissection regardless of anatomic location. Table 5 summarizes size threshold for prophylactic aortic root or ascending aortic aneurysm resection for various conditions.
- Proximal dissections (acute type A) require emergent surgery to prevent rupture or pericardial effusion.
- Distal dissections (Stanford type B) are usually treated medically unless distal organ involvement or impending rupture occurs.
  1. Surgical intervention for distal dissections is reserved for patients who have a complicated course, including occlusion of a major aortic branch, propagation of the dissection, enlarging aneurysm, and evidence of aortic rupture.
  2. Thoracic endovascular aortic repair (TEVAR) is a less invasive option for complicated type B aortic dissections and is associated with lower short- and midterm mortality than medical therapy. Indications for thoracic endovascular aortic repair for type B aortic dissection are summarized in Table 6.
  3. For acute type B dissections, in-hospital mortality in patients managed surgically has been reported to be 33.9% versus those managed with endovascular treatment at 10.6%.
  4. Independent predictors of complication and mortality in distal dissections include periaortic hematoma and descending aortic diameter >5.5 cm, partial false lumen thrombosis, primary tear >10 mm, one entry tear, and false lumen >22 mm.
  5. There is ongoing debate about a possible beneficial role of TEVAR for uncomplicated type B dissections. Data suggest that 30% of uncomplicated type B dissections will progress to an aneurysm.

ACUTE GENERAL Rx

- Admit to ICU for monitoring.
- Target systolic blood pressure 100 to 120 mm Hg; heart rate <60 beats/min to reduce aortic wall stress. Treatment with beta-blockers has been associated with improved survival in all patients with acute aortic dissections.
- IV beta-blockers are cornerstones of treatment, but multiple medications may be needed.
  1. Propranolol 1 mg every 3 to 5 min, metoprolol 5 mg IV every 5 min, or labetalol 20 mg IV, then 20 to 80 mg every 10 min, followed by nitroprusside 0.3 to 10 mcg/kg/min.
  2. Vasodilators should not be used without beta-blockade as they can induce reflex sympathetic stimulation and increase aortic shear stress.
  3. IV calcium channel blockers with negative inotropy (i.e., verapamil, diltiazem) may be used if beta-blockers are contraindicated.
- Pain control, often with morphine.

TABLE 5 Size Threshold for Prophylactic Aortic Root or Ascending Aortic Aneurysm Resection for Various Conditions

Condition	Size Threshold*
Degenerative aneurysm	≥5.5 cm
Bicuspid aortic valve	≥5.5 cm
Bicuspid aortic valve with risk factors or low surgical risk†	≥5.0 cm
Bicuspid aortic valve requiring aortic valve replacement	>4.5 cm
Marfan syndrome	≥5.0 cm
Marfan syndrome with risk factors‡	>4.5 cm
Loeys-Dietz syndrome§	4.0-4.5 cm
Familial thoracic aortic aneurysm syndromes¶	4.5-5.0 cm
Turner syndrome	>2.5 cm/m^2

*Lower thresholds for intervention may be considered according to body surface area in patients of small stature or in the case of rapid growth of the aorta. Age, body size, rapid growth, family history, risk of surgery, and patient and physician wishes may influence aortic size threshold.
†Family history of aortic dissection or aortic growth rate of 0.5 cm or more per yr or if the patient is at low surgical risk (<4%) and the surgery is performed by an experienced aortic surgical team in a center with established expertise in these procedures. Other risk factors for aortic dissection include coarctation of the aorta, hypertension, and the root phenotype of bicuspid aortic valve.
‡Family history of aortic dissection or rapid aortic growth (>3 mm/yr), or severe aortic or mitral regurgitation. If pregnancy desired, consider prophylactic aortic surgery for aortic diameter of 4.0 to 4.5 cm.
§It is reasonable to consider surgical repair of the aorta in adults with Loeys-Dietz syndrome or a confirmed *TGFBR1* or *TGFBR2* mutation with aortic diameter of 4.2 cm or more by transesophageal echocardiogram or 4.4 to 4.6 or more by CT or MRI. Aortic surgery at smaller diameters may be recommended when there are severe craniofacial features, rapid growth, or a family history of aortic dissection.
¶Surgical thresholds vary depending on the specific gene mutation involved. TAA caused by *ACTA2*, *SMAD3*, and *MYLK* may lead to aortic dissection at relatively small aortic diameters.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

TABLE 6 Indications for Thoracic Endovascular Aortic Repair for Type B Aortic Dissection*

Rupture
Impending rupture
Malperfusion
Hemorrhagic pleural effusion
Refractory pain
Refractory hypertension
Aneurysmal dilation (>55 mm)
Rapid increase in diameter
Recurrent symptoms

*Or open surgical repair if anatomy is unsuitable for TEVAR.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

CHRONIC Rx

- Chronic aortic dissection (>2 wk) managed with aggressive blood pressure control; target <120/80 mm Hg in most patients
- Statin therapy to reduce low-density lipoprotein <70 mg/dl
- Tobacco cessation
- Minimize strenuous physical activity such as heavy lifting
- Serial imaging of the aorta, with multidetector CT or MRI should be performed at presentation, at 1, 3, 6, and 12 months given the higher risk of instability early on, followed by yearly clinical and imaging follow-up
- As stated above, endovascular repair should be considered in complicated chronic type B dissections, i.e., when the aortic diameter exceeds 5.5 cm, when there is uncontrolled pain or blood pressure, or when there is rapid growth of the dissecting aneurysm (>4 mm per yr)

TABLE 7 Suggested Imaging Surveillance of Asymptomatic Thoracic Aortic Aneurysms*

Initial Discovery of Aneurysm	Repeated Imaging at 6 Months to Document Stability
Degenerative aneurysm†	
3.5-4.4 cm	Annual imaging
4.5-5.4 cm	Annual to biannual imaging
MFS, BAV with TAA, and familial TAA	
3.5-4.4 cm	Annual imaging
4.5-5.0 cm	Biannual imaging
LDS‡	
<4 cm	At least annual imaging
>4 cm	Biannual imaging

BAV, Bicuspid aortic valve; *LDS,* Loeys-Dietz syndrome; *MFS,* Marfan syndrome; *TAA,* thoracic aortic aneurysm.
*For aneurysms growing rapidly, more frequent imaging is recommended. Management of TAA must take into account the family history, age, body size, sex, rate of aneurysm growth, and underlying disease.
†For relatively small degenerative aneurysms found by imaging to be stable from year to year, imaging may be performed every 2 to 3 yr (Hiratzka et al).
‡Some recommend surgery for aortic root dimensions larger than 4 cm in adults with LDS, whereas the American College of Cardiology/American Heart Association guidelines for thoracic aortic disease recommend prophylactic surgery at 4.2 cm by TEE and 4.4 to 4.6 cm by CT or MRI (Hiratzka et al).
From Hiratzka LF et al: 2010 ACCF/AHA/AATS/ACR/ASA/SCA/SCAI/SIR/STS/SVM guidelines for the diagnosis and management of patients with thoracic aortic disease: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines, American Association for Thoracic Surgery, American College of Radiology, American Stroke Association, Society of Cardiovascular Anesthesiologists, Society for Cardiovascular Angiography and Interventions, Society of Interventional Radiology, Society of Thoracic Surgeons, and Society for Vascular Medicine, *Circulation* 121:e266, 2010.; Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.

DISPOSITION

- 90% mortality rate within 2 wk for an untreated type A dissection.
- Proximal dissection is a surgical emergency. Time is critical; mortality rate is 1% to 3% per hour, approaching 70% after 48 hr.
- Overall, in-hospital mortality rate is 22% with proximal dissections (27% treated surgically and 56% treated medically) and 10% to 17% with distal dissections.
- Table 7 summarizes suggested imaging surveillance of asymptomatic thoracic aortic aneurysms.

REFERRAL

For ICU management and surgical intervention

PEARLS & CONSIDERATIONS

- Blood pressure control is essential; beta-blocker is first-line medication.
- Proximal dissection is a surgical emergency.
- Cardiac tamponade is not uncommon in patients with acute type A aortic dissection. Syncope, altered mental status, and a widened mediastinum on chest radiograph on presentation suggest tamponade, which warrants urgent operative therapy.
- Surgery for acute type A aortic dissection in patients ≥70 yr old can be performed with acceptable outcomes.

BASIC INFORMATION

DEFINITION

Aortic regurgitation (AR) is abnormal retrograde blood flow into the left ventricle from the aorta due to an inadequately closing aortic valve (AV). It can be acute or chronic in nature.

Stages of chronic aortic regurgitation:

- Stage A = at risk of aortic insufficiency (AI) without even trace AR (e.g., bicuspid AV, AV sclerosis, diseases of the ascending aorta, history of rheumatic heart disease, or infective endocarditis)
- Stage B = progressive AI with mild to moderate AR and preserved left ventricular ejection fraction (LVEF)
- Stage C = asymptomatic severe AR with preserved (stage C1) or reduced (stage C2) LVEF
- Stage D = symptomatic severe AR

SYNONYMS

Aortic insufficiency
AI
AR

ICD-10CM CODES	
I35.1	Nonrheumatic aortic (valve) insufficiency
I35.2	Nonrheumatic aortic (valve) stenosis with insufficiency
I06.2	Rheumatic aortic stenosis with insufficiency
Q23.1	Congenital insufficiency of aortic valve

EPIDEMIOLOGY & DEMOGRAPHICS

Prevalence varies with severity of AR, age, and gender, as summarized in Table 1.

- Most common cause in the developing world is rheumatic heart disease
- Most common causes in developed countries are aortic root dilation, congenital bicuspid aortic valve, and calcific valve disease
- Infectious endocarditis (IE) is the most frequent cause of acute AR

TABLE 1 Prevalence of Aortic Regurgitation (AR)

Mild AR Prevalence	Male	Females
Age 50-59	3.7 %	1.9%
Age 60-69	12.1%	6%
Age 70-83	12.2%	14.6%
Moderate-Severe AR Prevalence	**Male**	**Females**
Age 50-59	0.5%	0.2%
Age 60-69	0.6%	0.8%
Age 70-83	2.2%	2.3%

From Singh JP et al: Prevalence and clinical determinants of mitral, tricuspid, and aortic regurgitation (the Framingham Heart Study), *Am J Cardiol* 83:897, 1999.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Clinical presentation varies depending on whether AR is acute or chronic. Chronic AR is well tolerated (except when secondary to IE), and patients remain asymptomatic for years. Common manifestations after significant deterioration of LVEF are dyspnea on exertion, syncope, chest pain, and congestive heart failure (CHF). The stages of chronic AR are summarized in Table 2. Acute severe AR manifests primarily with hypotension caused by a sudden fall in cardiac output and resultant cardiogenic shock. A rapid rise in left ventricular diastolic pressure results in a further decrease in coronary blood flow.

Physical findings in chronic AR:

- Widened pulse pressure (markedly increased systolic blood pressure with decreased diastolic blood pressure). Fig. E1 illustrates characteristics of the AR murmur
- Findings associated with widened pulse pressure:
  1. Bounding, "water hammer," or collapsing pulse **(*Corrigan* pulse)** can be palpated at the wrist or femoral artery and is caused by the rapid rise and sudden collapse of arterial pressure during late systole.
  2. Head "bobbing" with each heart beat **(*de Musset* sign).**
  3. "Pistol shot femorals" **(*Traube* sign)** describes a loud sound over the femoral artery with systole and diastole.
  4. Capillary pulsations **(*Quincke* sign)** may occur on the lips or at the base of the nail beds.
  - A to-and-fro intermittent femoral murmur **(*Duroziez* sign)** may be heard with slight compression of the femoral arteries. Popliteal systolic pressure increased >20 mm Hg over the brachial systolic pressure **(*Hill* sign);** a 40 to 60 mm difference represents moderate AR and >60 mm difference, severe AR
- Findings more of historical than practical interest, which are neither sensitive nor specific, include:
  1. ***Mueller* sign**—Systolic pulsations of the uvula
  2. ***Becker* sign**—Visible pulsations of the retinal arteries and pupils
  3. ***Mayne* sign**—More than a 15 mm Hg decrease in diastolic blood pressure with arm elevation from the value obtained with the arm in the standard position
  4. ***Rosenbach* sign**—Systolic pulsations of the liver
  5. ***Gerhard* sign**—Systolic pulsations of the spleen

Cardiac auscultation reveals:

- Displacement of cardiac impulse downward and to the patient's left
- S_3 heard over the apex
- Decrescendo, blowing diastolic murmur heard along left sternal border
- Low-pitched apical diastolic rumble **(*Austin Flint* murmur)**—the precise etiology is uncertain, but it is generally believed to be related to increased velocity of mitral inflow consequent to the AR
- Early systolic ejection sound and systolic ejection murmur

In patients with acute aortic insufficiency both the wide pulse pressure and the large stroke volume are absent. A short, blowing diastolic murmur may be the only finding on physical examination.

ETIOLOGY

- Leaflet abnormalities:
  1. Infective endocarditis
  2. Rheumatic fibrosis (most common cause in developing countries)
  3. Trauma with valvular rupture
  4. Congenital heart disease (bicuspid aortic valve—most common cause in the U.S., sinus of Valsalva aneurysm)
  5. Myxomatous degeneration
  6. Calcific AV disease
  7. Drug-induced (fenfluramine, dexfenfluramine, pergolide, cabergoline)
  8. Systemic rheumatic disorders (ankylosing spondylitis, rheumatoid arthritis, systemic lupus erythematosus)
- Aortic root or ascending aorta abnormalities:
  1. Annuloaortic ectasia
  2. Genetic syndromes (Ehlers-Danlos, Marfan)
  3. Trauma
  4. Ankylosing spondylitis
  5. Syphilitic aortitis
  6. Systemic hypertension
  7. Aortic dissection
- Postprocedural AR, usually due to a paravalvular leak, occurs in 10% to 20% of patients undergoing transcatheter aortic valve replacement (TAVR). Patients with more than mild AR after TAVR have worse outcomes than those without AR.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Patent ductus arteriosus, pulmonary regurgitation, and other valvular abnormalities.
- The differential diagnosis of cardiac murmurs is described in Sections II and III.

WORKUP

- Echocardiogram, chest radiograph, electrocardiogram (ECG), cardiac magnetic resonance (CMR) imaging, and cardiac catheterization (selected patients).
- Medical history and physical examination focused on dyspnea on exertion, syncope, chest pain, and CHF

IMAGING STUDIES

- Chest radiography:
  1. Left ventricular hypertrophy (LVH) (chronic AR)
  2. Aortic dilation
  3. Normal cardiac silhouette with pulmonary edema: Possible in patients with acute AR

TABLE 2 Stages of Chronic Aortic Regurgitation

Stage	Definition	Valve Anatomy	Valve Hemodynamics	Hemodynamic Consequences	Symptoms
A	**At risk of AR**	Bicuspid aortic valve (or other congenital valve anomaly) Aortic valve sclerosis Diseases of the aortic sinuses or ascending aorta History of rheumatic fever or known rheumatic heart disease IE	AR severity none or trace	None	None
B	**Progressive AR**	Mild to moderate calcification of a trileaflet valve bicuspid aortic valve (or other congenital valve anomaly) Dilated aortic sinuses Rheumatic valve changes Previous IE	***Mild AR:*** Jet width <25% of LVOT vena contracta <0.3 cm RVol <30 ml/beat RF <30% ERO <0.10 cm^2 Angiography grade 1+ ***Moderate AR:*** Jet width 25-64% of LVOT Vena contracta 0.3-0.6 cm RVol 30-59 ml/beat RF 30-49% ERO 0.10-0.29 cm^2 Angiography grade 2+	Normal LV systolic function Normal LV volume or mild LV dilation	None
C	**Asymptomatic severe AR**	Calcific aortic valve disease Bicuspid valve (or other congenital abnormality) Dilated aortic sinuses or ascending aorta Rheumatic valve changes IE with abnormal leaflet closure or perforation	***Severe AR:*** Jet width ≥65% of LVOT Vena contracta >0.6 cm Holodiastolic flow reversal in the proximal abdominal aorta RVol ≥60 ml/beat RF ≥50% ERO ≥0.3 cm^2 Angiography grade 3+ to 4+ In addition, diagnosis of chronic severe AR requires evidence of LV dilation	*C1:* Normal LVEF (≥50%) and mild-to-moderate LV dilation (LVESD ≤50 mm) *C2:* Abnormal LV systolic function with depressed LVEF (<50%) or severe LV dilation (LVESD >50 mm or indexed LVESD >25 mm/m^2)	None; exercise testing is reasonable to confirm symptom status

- ECG is not useful for diagnostic purposes but is commonly used in evaluation of patients with chronic AR to exclude associated arrythmia. Typical findings on an ECG are LVH as a result of volume overload.
- Echocardiography (Fig. E2) is the main imaging modality to diagnose AR and assess left ventricular size and function. Quantification of the severity of regurgitation can be made either qualitatively by Doppler vena contracta width (severe if >0.6 cm) or quantitatively by effective regurgitant orifice area (severe if >0.30 cm^2) and/or regurgitant volume (severe if >60 ml per/beat).
- CMR is indicated (class 1) in patients with moderate or severe AR and suboptimal echocardiographic images for the assessment of AR severity as well as LV systolic function and volumes.
- Cardiac catheterization is indicated in selected patients to assess the degree of left ventricular dysfunction and AR when echocardiographic parameters are inconclusive, and to determine if there is coexistent coronary artery disease.
- Serial evaluation of the size and morphology of the aortic sinuses and ascending aorta by echocardiography, CMR, or CT angiography is recommended in patients with a bicuspid

AV and an aortic diameter >4.0 cm, with the examination interval determined by the degree and rate of progression of aortic dilation and by family history. Patients with an aortic diameter >4.5 cm should be evaluated annually (Class 1).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of competitive sports and heavy weight lifting if: severe AR, patient is symptomatic, ejection fraction <50%, AR is associated with aortic root dilation
- Salt restriction
- Endocarditis prophylaxis is not recommended for chronic AR patients with native valves undergoing invasive procedures. However, antibiotic prophylaxis is recommended for patients with a prior history of infective endocarditis or a presence of prosthetic heart valve

ACUTE GENERAL Rx

- Emergent AV replacement (preferred) or repair for acute, severe AR
- Intraaortic balloon pump is contraindicated
- Afterload reduction: Angiotensin-converting enzyme (ACE) inhibitors and vasodilators (i.e., nitroprusside) in acute AR; diuretics for pulmonary edema
- Avoid beta-blockers that can prolong diastole
- Emergent surgical referral for cardiogenic shock

CHRONIC Rx

Management depends on whether patients are symptomatic and candidates for valve surgery. ACC/AHA guidelines for aortic valve replacement for chronic aortic regurgitation are summarized in Table 3.

- Symptomatic patients with severe AR who are candidates for valve surgery should proceed with valve replacement after medical optimization of heart failure. When surgery is contraindicated, TAVR is currently under assessment for treatment of native AR.
- Asymptomatic patients with severe AR and systolic dysfunction who are not surgical candidates should receive ACE/ARBs.
- Other medical treatments for AR are based on limited studies. Beta-blocker use is controversial but has been associated with a higher survival rate in severe AR. Vasodilatory therapies (nifedipine and enalapril) have failed to show benefit in reducing the need for or delaying AV replacement in asymptomatic, severe AR with normal systolic function, but ACE/ARB therapy may indeed benefit moderate to severe AR. Long-term vasodilator therapy with ACE inhibitors or nifedipine may be used in patients who have concomitant hypertension. There is no current definitive indication of medical therapy with afterload reduction for aortic regurgitation other than hypertension control.
- Beta-blockers in combination with ACE inhibitors are reasonable in patients with symptomatic severe AR or LV dysfunction when surgery cannot be performed because of concomitant comorbidities. In a retrospective cohort study of 756 patients with chronic AR, beta-blocker therapy was associated with decreased mortality. Patients treated with beta-blockers were more likely to be taking ACE inhibitors and dihydropyridine calcium channel blockers as well (53% vs. 40%). In the same study, patients treated with beta-blockers and undergoing AVR were also noted to have a mortality benefit.
- Diuretics and sodium restriction for CHF.
- Comparable efficacy of losartan and atenolol was shown in curbing aortic root dilatation growth in children and young adults (6 mo to 25 yr) with Marfan syndrome with similar outcomes of aortic regurgitation severity, surgery, aortic dissection, and death at 3 yr. Fig. 3 describes a management strategy for patients with chronic severe AR.

TABLE 3 American College of Cardiology/American Heart Association Guidelines for Aortic Valve Replacement (AVR) for Chronic Aortic Regurgitation (AR)

Class	Indication	Loe
I	AVR for symptomatic patients with severe AR regardless of LV systolic function (stage D).	B
	AVR for asymptomatic patients with chronic severe AR and LV systolic dysfunction (LVEF <50%) (stage C2).	B
	AVR for patients with severe AR (stage C or D) while undergoing cardiac surgery for other indications.	C
IIa	AVR is reasonable for asymptomatic patients with severe AR with normal LV systolic function (LVEF ≥50%), but severe LV dilation (stage C2, LVESD >50 mm).	B
	AVR is reasonable in patients with moderate AR (stage B) who are undergoing other cardiac surgery.	C
IIb	AVR may be considered for asymptomatic patients with severe AR and normal LV systolic function (stage C1, LVEF ≥50%) but severe LV dilation (LVEDD >65 mm) if surgical risk is low.*	C

*Particularly in the setting of progressive LV enlargement.
LOE, Level of evidence; *LV,* left ventricular; *LVEDD,* LV end-diastolic dimension; *LVEF,* LV ejection fraction; *LVESD,* LV end-systolic dimension.

REFERRAL

Surgical referral is reserved for the following patients:

- Patients with acute severe AR (i.e., infective endocarditis) and cardiogenic shock
- Symptomatic patients with severe AR regardless of LV systolic function (class I)
- Patients with hemodynamically stable severe AR undergoing CABG or surgery on the aorta or other heart valves
- Evidence of systolic dysfunction with left ventricular ejection fraction of less than 50% and asymptomatic patients with chronic severe AR
- Asymptomatic patients with severe AR and left ventricular ejection fraction >50%, but with left ventricular dilation:
  1. Echocardiographic end-systolic dimension >50 mm (Class IIa level of evidence) *or;*
  2. Echocardiographic end-diastolic dimension >65 mm with low surgical risk (Class IIb)

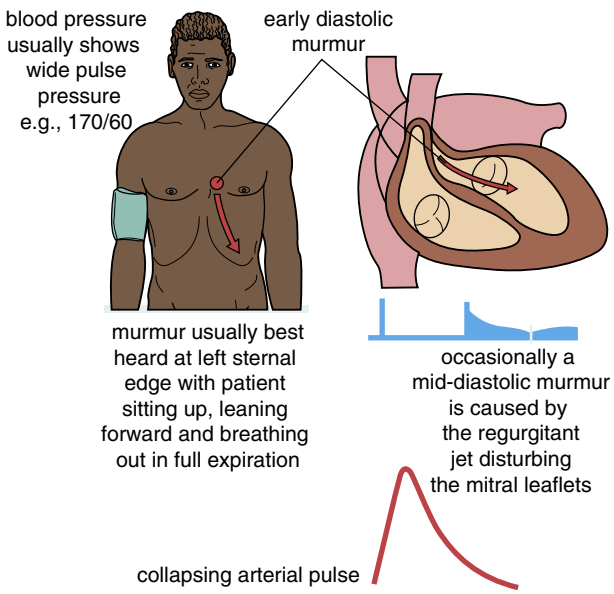

FIG. E1 Aortic regurgitation as an example of an early diastolic murmur. (From Epstein O et al: *Pocket guide to clinical examination,* ed 4, St Louis, 2009, Mosby.)

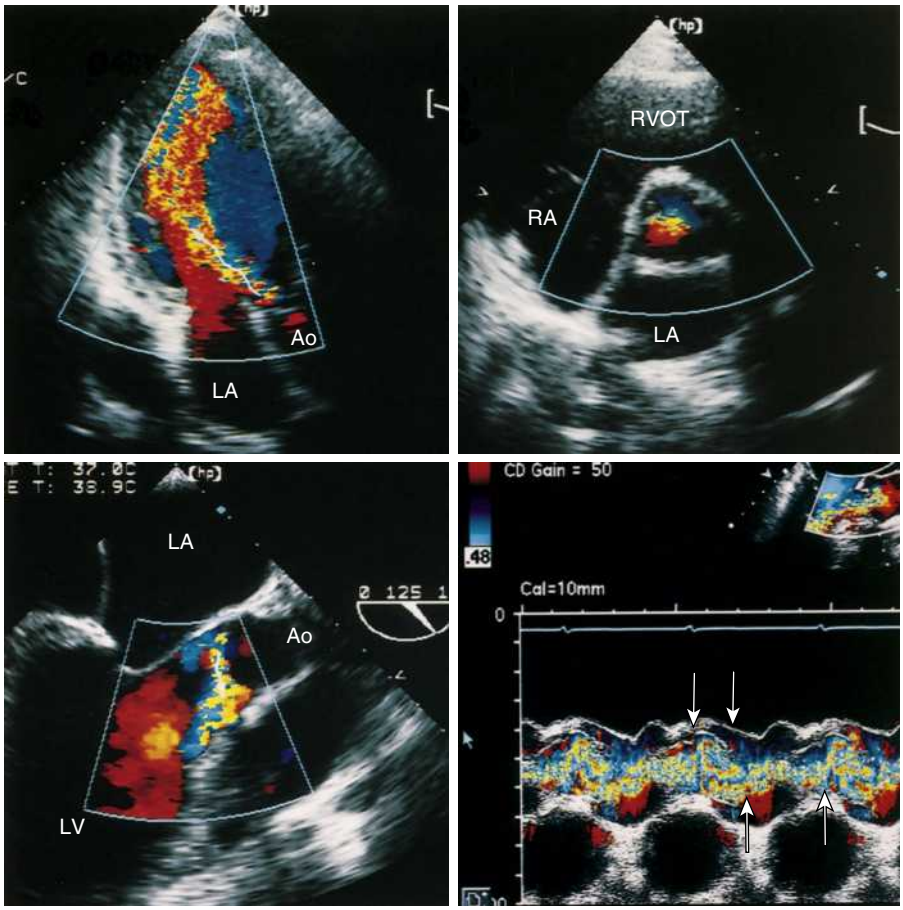

FIG. E2 Composite of echocardiograms recorded in patients with aortic regurgitation. The two top panels were recorded in the same patient and show, on the left, an apical long-axis view and, on the right, a parasternal short-axis view. In the apical long-axis view, note the fairly extensive confetti-like aortic regurgitation jet arising from the proximal aorta and traversing to the left ventricular apex. Note also that the aortic regurgitation jet velocities merge with the mitral inflow velocities, rendering quantitation problematic. The top right panel is recorded in the same patient and shows a central aortic regurgitation jet. The bottom left panel is a transesophageal echocardiogram recorded in a longitudinal view. Note the highly eccentric aortic regurgitation jet that appears to fill the entire width of the left ventricular outflow tract. This apparent filling of the left ventricular outflow tract is due to the posterior to anterior jet direction *(white arrow)* rather than to a substantial true width of the jet. The bottom right panel is a color M-mode echocardiogram recorded in a patient with aortic insufficiency in which the normal systolic flow can be appreciated as well as a continuous diastolic flow in the lumen of the aorta that represents aortic insufficiency. The two downward-pointing arrows denote the duration of systole, and the two upward-pointing arrows indicate the duration of diastole. *Ao,* Aorta; *LA,* left atrium; *LV,* left ventricle; *RA,* right atrium; *RVOT,* right ventricular outflow tract. (From Zipes DP et al [eds]: *Braunwald's heart disease,* ed 7, Philadelphia, 2005, Saunders.)

BASIC INFORMATION

DEFINITION

Aortic stenosis (AS) is obstruction of left ventricular systolic outflow due to aortic valve thickening/calcification generating a significant pressure gradient (aortic jet velocity of at least 2 m/sec). Symptoms typically appear when the valve orifice decreases to <1 cm^2 (normal orifice is 3 to 4 cm^2). Criteria for severe AS include a valve area <1.0 cm^2, a mean gradient >40 mm Hg, or a peak gradient >4 m/s. Doppler aortic jet velocities >5 m/sec is defined as very severe.

SYNONYMS

Aortic valve stenosis
AS

ICD-10CM CODES

I35.0	Nonrheumatic aortic (valve) stenosis
I35.2	Nonrheumatic aortic (valve) stenosis with insufficiency
Q23.0	Congenital stenosis of aortic valve

ETIOLOGY

- Idiopathic calcification of the aortic valve (most common cause in North America and Europe, presents at ages 60 to 80)
- Rheumatic heart disease: Characterized by commissural fusion leaving a small central orifice (most common cause worldwide)
- Progressive stenosis of congenital unicuspid or bicuspid valve (found in 1% to 2% of the population, presents at ages <30 yr for unicuspid and at ages 40 to 60 for bicuspid valves)
- Less common causes include rare metabolic disease (Fabry disease), systemic lupus erythematosus, radiation, end-stage renal disease, and obstructive vegetations/endocarditis may all cause early development of AS
- Genetic variation in the LPA locus, mediated by Lp(2) levels, is associated with aortic valve calcification across multiple ethnic groups and with incidental clinical aortic stenosis

EPIDEMIOLOGY & DEMOGRAPHICS

- Aortic stenosis is the most common valve lesion in adults in North America and Europe.
- The prevalence demonstrates a strong relationship with age, affecting 0.2% between ages 50 and 59 yr, 1.3% between 60 and 69 yr, 3.9% between 70 and 79 yr, and 9.8% between ages 80 and 89.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Harsh midsystolic, crescendo-decrescendo murmur (Fig. 1) best heard at base of heart and radiating into neck vessels; often associated with a thrill or ejection click; may also be heard well at the apex.
- Signs of severe AS include absent or diminished intensity of the second heart sound and/or slow-rising carotid upstroke with delayed amplitude (pulsus parvus et tardus), presence of S4, and a reverse splitting of the second heart sound.
- Early symptoms include decreased exercise tolerance, dyspnea on exertion, exertional dizziness or syncope, and exertional angina.
- Late symptoms include angina (secondary primarily to reduced coronary blood flow and increased total left ventricle [LV] oxygen demand), syncope, and heart failure.
- Table 1 summarizes the stages of valvular aortic stenosis.
- Pathophysiology: Antegrade velocities remain normal until the cross-sectional area of the left ventricular outflow tract (typically 3 to 4 cm^2) is reduced by roughly half. At this point, secondary to the increased resistance, the left ventricle systolic pressure starts to increase and the LV adapts with concentric hypertrophy. The hypertrophy allows for normalization of the wall stress and preservation of the ejection fraction, cardiac output, and left ventricular end diastolic pressures despite the LV/peripheral arterial system pressure gradient.
- LV hypertrophy eventually leads to LV diastolic dysfunction, which may herald early symptoms. That said, symptoms generally do not begin until stenosis becomes severe (valve area <1.0 cm^2, a mean gradient >40 mm Hg, or a peak gradient >4 m/s).
- For most patients, after becoming symptomatic, LV systolic function will begin to drop (decreased cardiac output and stroke volume) with development of signs and symptoms of overt heart failure. At this point, if a symptomatic severe AS patient does not

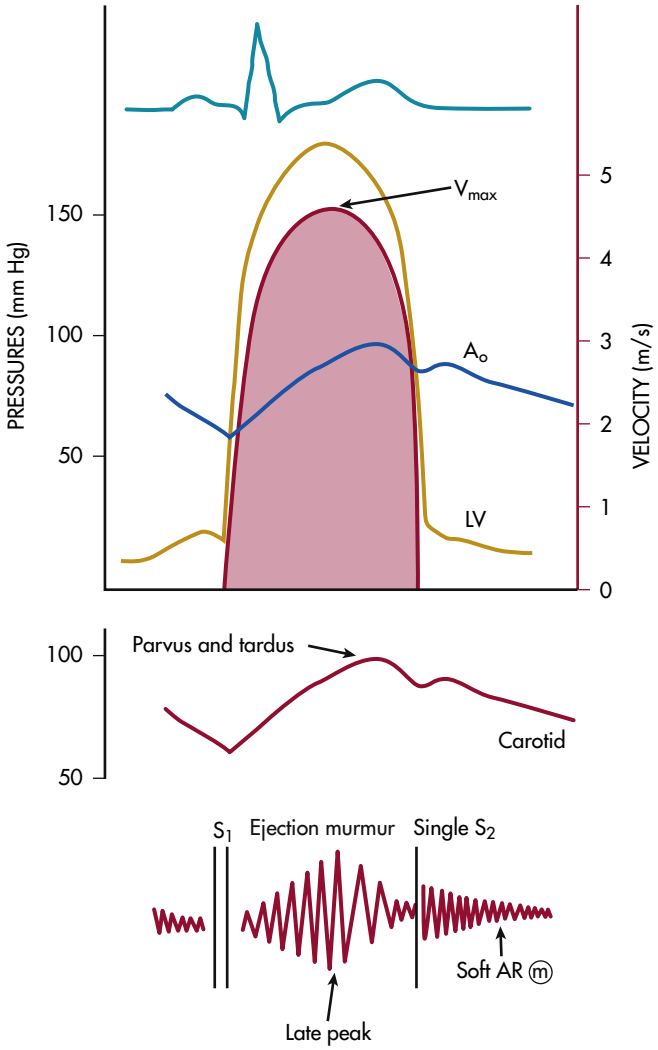

FIG. 1 Relationship between left ventricle (LV) and aortic (Ao) pressures and the Doppler aortic stenosis velocity curve *(in red)*. The pressure difference between the LV and aorta in systole is four times the velocity squared (the Bernoulli equation). Thus, a maximum velocity (Vmax) of 4.3 m/sec corresponds to a maximum LV to Ao pressure difference of 74 mm Hg and a mean systolic gradient of 44 mm Hg. On physical examination, the slow rate of rise and delayed peak in the carotid pulse (or parvus and tardus) matches the contour of the aortic pressure waveform. The murmur corresponds to the Doppler velocity curve with a harsh crescendo-decrescendo late-peaking systolic murmur, best heard at the aortic region (upper right sternal border). Often, a soft, high-pitched diastolic decrescendo murmur of aortic regurgitation also is appreciated. (From Bonow et al [eds]: *Braunwald's heart disease,* ed 9, Philadelphia, 2012, Saunders.)

TABLE 1 Stages of Valvular Aortic Stenosis

Stage	Definition	Valve Anatomy	Valve Hemodynamics	Hemodynamic Consequences	Symptoms
A	**At risk of AS**	Bicuspid aortic valve (or other congenital valve anomaly) Aortic valve sclerosis	Aortic Vmax <2 m/sec	None	None
B	**Progressive AS**	Mild to moderate leaflet calcification of a bicuspid or trileaflet valve with some reduction in systolic motion or rheumatic valve changes with commissural fusion	***Mild AS:*** Aortic Vmax 2.0-2.9 m/sec or mean ΔP <20 mm Hg ***Moderate AS:*** Aortic Vmax 3.0-3.9 m/sec or mean ΔP 20-39 mm Hg	Early LV diastolic dysfunction may be presentNormal LVEF	None
C	**Asymptomatic severe AS**				
C1	Asymptomatic severe AS with preserved LVEF	Severe leaflet calcification or congenital stenosis with severely reduced leaflet opening	***Severe AS:*** Aortic Vmax ≥4 m/sec or mean ΔP ≥40 mm Hg AVA typically is ≤1 cm^2 (or AVAi ≤0.6 cm^2/m^2) Very severe AS is an aortic Vmax ≥5 m/sec, or mean ΔP ≥60 mm Hg	LV diastolic dysfunction Mild LV hypertrophy Normal LVEF	None; exercise testing is reasonable to confirm symptom status
C2	Asymptomatic severe AS with LV dysfunction	Severe leaflet calcification or congenital stenosis with severely reduced leaflet opening	Aortic Vmax ≥4 m/sec or mean ΔP ≥40 mm Hg AVA typically is ≤1 cm^2 (or AVAi ≤0.6 cm^2/m^2)	LVEF <50%	None
D	**Symptomatic severe AS**				
D1	Symptomatic severe high-gradient AS	Severe leaflet calcification or congenital stenosis with severely reduced leaflet opening	***Severe AS:*** Aortic Vmax ≥4 m/sec, or mean ΔP ≥40 mm Hg AVA typically is ≤1 cm^2 (or AVAi ≤0.6 cm^2/m^2), but may be larger with mixed AS/AR	LV diastolic dysfunction LV hypertrophy Pulmonary hypertension may be present	Exertional dyspnea or decreased exercise tolerance Exertional angina Exertional syncope or presyncope
D2	Symptomatic severe low-flow/low-gradient AS with reduced LVEF	Severe leaflet calcification with severely reduced leaflet motion	AVA ≤1 cm^2 with resting aortic Vmax <4 m/sec, or mean ΔP <40 mm Hg Dobutamine stress echo shows AVA ≤1 cm^2 with Vmax ≥4 m/sec at any flow rate	LV diastolic dysfunction LV hypertrophy LVEF <50%	HF, angina, syncope or presyncope
D3	Symptomatic severe low-gradient AS with normal LVEF or paradoxical low-flow severe AS	Severe leaflet calcification with severely reduced leaflet motion	AVA ≤1 cm^2 with aortic Vmax <4 m/sec, or mean ΔP <40 mm HgAVAi ≤0.6 cm^2/m^2 Stroke volume index <35 ml/m^2 Measured when the patient is normotensive (systolic BP <140 mm Hg)	Increased LV relative wall thickness Small LV chamber with low-stroke volume. Restrictive diastolic filling LVEF ≥50%	HF, angina, syncope or presyncope

AR, Aortic regurgitation; *AS,* aortic stenosis; *AVA,* aortic valve area; *AVAi,* aortic valve area indexed to body surface area; *BP,* blood pressure; *HF,* heart failure; *LV,* left ventricle; *LVEF,* left ventricular ejection fraction; *ΔP,* pressure gradient; *Vmax,* maximum aortic velocity. From Nishimura RA et al: 2014 AHA/ACCF guideline for the management of patients with valvular heart disease: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines. In Mann DL et al (eds): *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.

undergo valve replacement, their mortality drastically increases.
- Acquired von Willebrand disease is seen in approximately 20% of severe AS, which can lead to GI bleeding from angiodysplasia (Heyde syndrome) that resolves after aortic valve replacement.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hypertrophic cardiomyopathy
- Mitral regurgitation
- Ventricular septal defect
- Aortic sclerosis. Aortic stenosis is distinguished from aortic sclerosis by the degree of valve impairment. In aortic sclerosis, the valve leaflets are abnormally thickened but obstruction to outflow is absent or minimal
- Subvalvular membrane or supravalvular AS
- Stages of valvular AS
  1. Stage A = at risk of AS
  2. Stage B = progressive AS (formerly known as mild and moderate AS)
  3. Stage C = asymptomatic severe AS
  4. Stage D = symptomatic severe AS

WORKUP

- Echocardiography: The primary test for diagnosis (see "Imaging Studies")
- ECG: May demonstrate left ventricular hypertrophy and/or left atrial abnormality
- Chest radiograph: May demonstrate cardiomegaly. Poststenotic dilation of the ascending aorta may also be evident
- Cardiac catheterization in selected patients (see "Imaging Studies")
- Dobutamine challenge (for low-gradient, low-flow AS)

IMAGING STUDIES

- Doppler echocardiography: Used to evaluate structure and anatomy of the valve. Hemodynamics can easily be assessed; allows calculation of both aortic valve area and estimation of pressure gradients to determine severity of AS (Fig. 2). Furthermore, allows evaluation of the LV size and function and pulmonary pressures.
- Chest x-ray:
  1. Poststenotic dilation of the ascending aorta
  2. Calcification of aortic cusps
  3. Rounding of left ventricle (LV) apex

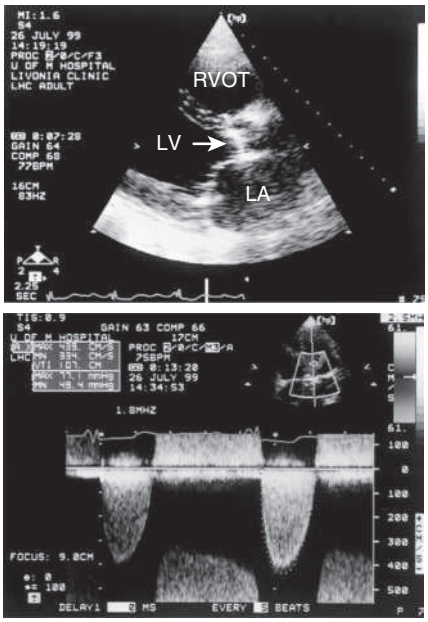

FIG. 2 Echocardiogram recorded in a patient with severe aortic stenosis. The *top panel* is a parasternal long-axis view recorded in systole. Left ventricular function is diminished. The aortic valve is markedly thickened and partially calcified. Its motion is markedly reduced, and in systole it appears that the valve occludes the orifice *(arrow)*. The *lower panel* is a continuous-wave Doppler recorded from the apex of the left ventricle along a line aimed through the stenotic aortic valve. Note the aortic stenosis signal below the zero crossing line. The peak velocity is 430 cm/sec, which corresponds to a maximum gradient of 77 mm Hg and a mean gradient of 49.4 mm Hg. *LA,* Left atrium; *LV,* left ventricle; *RVOT,* right ventricular outflow tract. (From Zipes DP et al [eds]: *Braunwald's heart disease,* ed 7, Philadelphia, 2005, Saunders.)

- ECG:
  1. Left ventricular hypertrophy (found in 80% of patients)
  2. Left atrial enlargement
  3. Atrial fibrillation (in late disease)
- Cardiac catheterization: Indicated in symptomatic patients awaiting aortic valve replacement (AVR) in order to detect coexisting coronary artery stenosis that may need bypass at the same time as aortic valve replacement. Previously, cardiac catheterization was used in symptomatic patients when noninvasive tests are inconclusive or when there is a discrepancy between noninvasive tests and clinical findings regarding severity of AS. Due to the increased risk of stroke when crossing the valve and with the advent of newer or improved imaging modalities (cardiac MR, PET-CT, TEE), there is rarely a role to directly measure the gradient across the valve.
- A CT with contrast for imaging the aorta may be needed for annular sizing, aortic measurements and if a transcatheter aortic valve replacement (TAVR) is planned, the CT scan is crucial to planning TAVR approach.
- Exercise testing: Strongly encouraged for any patient with stage C "asymptomatic" severe AS to evaluate exercise tolerance and to look for a fall in systemic blood pressure while exercising.

Rx TREATMENT

GENERAL Rx

MEDICAL:

- Once symptomatic, the mainstay of treatment is replacement of the valve. AS is a surgical disease. Fig. 3 summarizes a treatment strategy for patients with severe AS.
- Optimize loading conditions by keeping a normal volume status (gentle diuresis for volume overload as preload dependent) and controlling hypertension (HTN) but avoid vasodilators (nitrates); maintain sinus rhythm.
- In 2007, the AHA guidelines for prevention of infectious endocarditis were revised and routine antibiotic prophylaxis to undergo dental or other invasive procedures is no longer recommended, unless the patient has prior endocarditis.

INDICATIONS FOR AORTIC VALVE REPLACEMENT: Valve replacement is the treatment of choice in symptomatic patients because there is a 50% mortality rate at 2 yr with medical therapy alone. If a patient does not have a >1 yr life expectancy postprocedure or quality of life will not be improved by the aortic valve, then replacement should not be considered, but rather palliative therapies should be discussed. ACC/AHA guidelines for aortic valve replacement for aortic stenosis are summarized in Table 2.

Percutaneous aortic balloon valvuloplasty serves best as palliative therapy in severely symptomatic patients who are not surgical candidates and as a bridge to surgery in hemodynamically unstable adult patients. It is not an option in patients who are good candidates for valve replacement because restenosis occurs in most adult patients at 6 mo. Updated ACC /AHA guidelines for choice of surgical versus transcatheter treatment of aortic stenosis are summarized in Table 3.

If the patient does fulfill the intervention criteria (>1 yr life expectancy postprocedure and quality of life will be improved by the aortic valve), then replacement can be further considered.

Valve replacement is a **Class I Indication** for any patients with:

- Stage D1: Symptomatic severe AS
- Stage C2: Asymptomatic severe AS with LV ejection fraction (EF) <50%
- Stage C1 or C2: Asymptomatic severe AS undergoing CABG or surgery on the aorta or other heart valves

Valve replacement is a **Class IIa indication** for patients with:

- Stage D2: Low-flow/low gradient (with low ejection fraction <50%) with a positive low-dose dobutamine stress echo
- Stage D3: Symptomatic patients with low-flow/low gradient severe AS with a **normal LVEF** ≥50%, a valve area ≤1.0 cm^2, and a stroke volume index <35 ml/m^2
- (c) Stage C: Asymptomatic severe AS and abnormal blood pressure response (decrease in systolic blood pressure) or decreased exercise tolerance during exercise
- (d) Stage C: Asymptomatic patients with critical AS (peak velocity >5 m/s or mean pressure gradient >60 mm Hg) with low surgical risk
- (e) Stage B: Patients with moderate AS who are undergoing cardiac surgery for other indications

Valve replacement is a **Class IIb indication** for patients with:

- Stage C: Asymptomatic severe AS in a low-risk patient showing rapid progression of disease (Vmax >0.3m/s/yr).
- When deciding replacement strategy, surgical aortic valve replacement (SAVR) vs. transcatheter aortic valve replacement (TAVR), in all cases a heart team approach is a Class I indication. TAVR is a catheter-based technology that allows for implantation of a prosthetic valve without open heart surgery, decreasing recovery time and hospital stay. Historically, the replacement strategy has been driven by patient surgical risk. Primarily due to TAVR trial design, patients were classified by their STS-PROM score into four categories: extreme surgical risk (absolute surgical contraindication), high surgical risk (STS-PROM score >8), intermediate surgical risk (STS-PROM score 4 to 8), and low surgical risk (STS-PROM score <4).
- For the **extreme surgical risk** patients and **high surgical risk** patients (STS-PROM score >8), if a TAVR approach is feasible, then the recommendation is for a TAVR strategy. In a large meta-analysis of these high-risk patients with severe AS who were candidates for surgery, transfemoral TAVR (but not transthoracic TAVR) was associated with lower mortality at 2 yr. The surgical group had double the incidence of new-onset atrial fibrillation and major bleeding, but the TAVR group had a higher rate of paravalvular regurgitation and vascular complications.
- For **intermediate surgical risk** (STS-PROM 4 to 8), if TAVR approach is feasible and there is an absence of high-risk anatomical features that would increase the risk of a transcatheter approach, then the recommendation is for a TAVR strategy. In these intermediate-risk patients, transfemoral TAVR was associated with lower mortality rates, and nontransfemoral TAVR was similar to surgical aortic valve replacement with respect to death or disabling stroke rates, as demonstrated by the same large meta-analysis of four randomized trials. The notable differences were that TAVR resulted in larger aortic valve areas and had a lower rate of acute kidney injury, severe bleeding, and new-onset atrial fibrillation, whereas surgery resulted in fewer major vascular complications and less paravalvular aortic regurgitation.
- For **low surgical risk** patients (STS-PROM <4), if the patient meets the following four criteria: >65 yr old, transcatheter approach

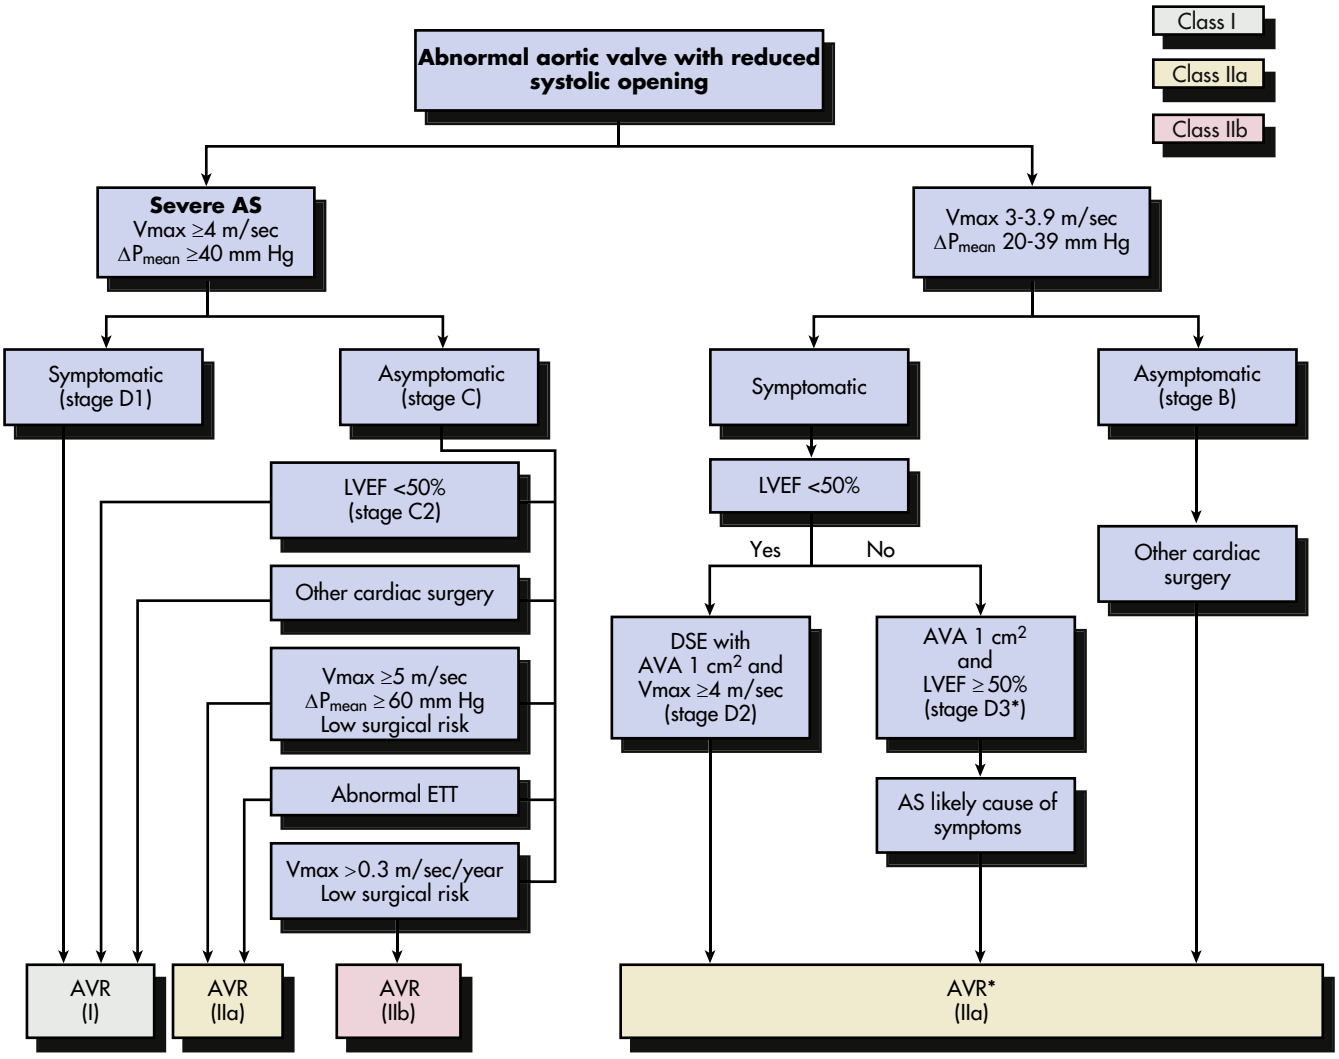

FIG. 3 Management strategy for patients with severe AS. Periodic monitoring is indicated for all patients in whom AVR is not yet indicated, including those with asymptomatic AS (stage B or C) and those with low-gradient AS (stage D2 or D3) who do not meet criteria for intervention. AVR should be considered with stage D3 AS only if valve obstruction is the most likely cause of symptoms, stroke volume index is <35 ml/m_2, indexed AVA is ≤0.6 cm_2/m_2, and data are recorded when the patient is normotensive (systolic BP <140 mm Hg). *AS,* Aortic stenosis; *AVA,* aortic valve area; *AVR,* aortic valve replacement; *BP,* blood pressure; *DSE,* dobutamine stress echocardiography; *ETT,* exercise treadmill test; *LVEF,* left ventricular ejection fraction; ΔP_{mean}, mean pressure gradient; *Vmax,* maximum velocity. (From Nishimura RA et al: 2014 AHA/ACC Guideline for the management of patients with valvular heart disease: a report of the American College of Cardiology /American Heart Association Task Force on Practice Guidelines. In Mann DL et al [eds]: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.)

is feasible, aortic valve is trileaflet, and there is an absence of high-risk anatomic features that would increase the risk of transcatheter approach, then the recommendation is for a TAVR strategy. For these low-risk patients, from the PARTNER 3 trial, there was a significant lower primary endpoint (composite death, stroke, or rehospitalization at 1 yr).

DISPOSITION

- The presence of even mild symptoms is an indicator of poor survival for patients with AS. The average duration of symptoms before death is angina, 5 yr; syncope, 3 yr; CHF, 2 yr.
- Approximately 75% of patients with symptomatic AS will die within 3 yr of symptom onset unless the aortic valve is replaced.

REFERRAL

- A heart team referral for valve replacement in all symptomatic AS patients (Class I indication). There are studies that are examining the presence of moderate or severe valvular calcification, together with a rapid increase in aortic jet velocity and elevated BNP, to identify patients with a very poor prognosis who should be considered for early valve replacement rather than delayed until symptoms develop. Additionally, patients with severe AS who are asymptomatic should be considered for exercise stress test to see if they are truly without symptoms (low exercise tolerance) or if the BP drops with exercise, both which would be indications for a heart team referral.
- In asymptomatic patients, Doppler echocardiography is recommended every 6 to 12 months for severe aortic stenosis, every 1 to 2 yr for moderate disease, and every 2 to 3 yr for mild disease. Should have a low threshold to repeated echocardiogram for any change in symptoms or exam.
- Referral to cardiology should be considered in any patients with severe AS and in particular those with low-flow, low-gradient (low

I	AVR with severe high-gradient AS who have symptoms by history or on exercise testing (stage D1).	B
	AVR for asymptomatic patients with severe AS (stage C2) and LVEF less than 50%.	B
	AVR for patients with severe AS (stage C or D) when undergoing other cardiac surgery.	B
IIa	AVR is reasonable for asymptomatic patients with very severe AS (stage C1, aortic velocity ≥5 m/sec) and low surgical risk.	B
	AVR is reasonable in asymptomatic patients (stage C1) with severe AS and decreased exercise tolerance or an exercise fall in blood pressure.	B
	AVR is reasonable in symptomatic patients with low-flow/low-gradient severe AS with reduced LVEF (stage D2) with a low-dose dobutamine stress study that shows an aortic velocity of 4 m/sec or more (or mean pressure gradient ≥40 mm Hg) with a valve area of 1.0 cm^2 or less at any dobutamine dose.	B
	AVR is reasonable in symptomatic patients with low-flow, low-gradient severe AS (stage D3) who are normotensive and have LVEF of 50% or greater, if clinical, hemodynamic, and anatomic data support valve obstruction as the most likely cause of symptoms.	C
	AVR is reasonable for patients with moderate AS (stage B) (aortic velocity, 3.0 to 3.9 m/sec) who are undergoing other cardiac surgery.	C
IIb	AVR may be considered for asymptomatic patients with severe AS (stage C1) and rapid disease progression and low surgical risk.	C

TABLE 3 Updated ACC/AHA Guidelines for Choice of Surgical Versus Transcatheter Treatment of Aortic Stenosis (AS)

Class	Indication	LOE
I	For patients in whom TAVR or high-risk surgical AVR is being considered, members of a heart valve team should collaborate to provide optimal patient care.	C
	Surgical AVR in symptomatic and asymptomatic patients with severe AS who meet an indication for AVR (listed in Table 2) when surgical risk is low or intermediate. (*Modified 2017*)	B
	TAVR in patients who meet an indication for AVR for AS who have a prohibitive surgical risk and a predicted post-TAVR survival >12 months. (*Modified 2017*)	A
	TAVR or surgical AVR in patients with severe AS who meet an indication for AVR and who have high surgical risk. (*Modified 2017*)	A
IIa	TAVR is a reasonable alternative to surgical AVR for symptomatic patients with severe AS and an intermediate surgical risk. (*New 2017*)	B
IIb	Percutaneous aortic balloon dilation may be considered as a bridge to surgical or transcatheter AVR in severely symptomatic patients with severe AS.	C
III	TAVR is not recommended in patients in whom the existing comorbidities would preclude the expected benefit from correction of AS.	B

LOE, Level of evidence; *AVR,* aortic valve replacement; *TAVR,* transcatheter AVR.
Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

ejection fraction) symptomatic aortic stenosis for further workup (dobutamine stress echo).
- Balloon valvuloplasty is useful in infants and children or poor surgical candidates who do not have calcified valve apparatus; it can be done as an intermediate procedure to stabilize high-risk patients before surgery.
- Role of palliative care:
  1. If life expectancy with aortic valve replacement (SAVR or TAVR) is <1 yr **or** the patient's quality of life is unlikely to improve after aortic valve replacement (due to coexisting significant comorbidities), palliative care consultation is extremely valuable as it focuses on shared decision making as well as improving quality of life without interruption of conservative medical therapy.

Aphthous Ulcers

BASIC INFORMATION

DEFINITION

Small painful ulcers predominantly of the oral mucosa

SYNONYMS

Aphthae
Canker sores
Recurrent aphthous stomatitis (RAS)
Recurrent oral aphthae

ICD-10CM CODE
K12.0 Recurrent oral aphthae

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Unknown
PEAK INCIDENCE: Adolescence
PREVALENCE: One in five individuals have been affected by aphthous ulcers in their lifetime.
PREDOMINANT SEX AND AGE: Most commonly affects women, adolescents, and young adults under the age of 40.
GENETICS: Up to 40% of patients have a family history of aphthous ulcers.
RISK FACTORS: Genetic factors, stress, trauma, tobacco, viral and bacterial infections, nutritional deficiencies, endocrine and immune disturbances

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Aphthous ulcers, also referred to as canker sores, are typically small round or oval-shaped lesions with a gray-white or yellow pseudomembranous base and erythematous halo (Fig. E1). Aphthous ulcers can affect any age group. However, they generally appear in childhood and subside by the third decade. The exact cause of aphthous ulcers is poorly understood, but multiple factors may play a role in their occurrence. These include, but are not limited to, trauma, nutritional deficiencies, viral and bacterial infections, medications, food hypersensitivities, hormonal or endocrine changes, and tobacco use. In the absence of systemic disease and in cases where aphthae reoccur, it is termed Recurrent Aphthous Stomatitis (RAS).
- **Recurrent aphthous stomatitis** has three subtypes including minor RAS (up to 80% of cases), major RAS (10% of cases), and herpetiform RAS (10%).
- **Minor RAS:** Classification of minor RAS depends on the number and size of the ulcers. Generally, 1 to 5 superficial aphthae less than 10 mm in size and localized to the lips, buccal mucosa, tongue, and floor of the mouth. Lesions tend to self-resolve in 4 to 14 days and leave no scarring.
- **Major RAS:** These lesions are similar in appearance to minor RAS except that their size, number, and location increase. Generally, they are greater than10 mm in diameter. They are deeper, extend to the gingiva and pharyngeal mucosa, last for weeks to months, and have a higher risk for scarring.
- **Herpetiform RAS:** Herpetiform lesions are often smaller, 1 to 3 mm. They are also deeper and in greater numbers (5 to 100). Ulcers are generally gray with irregular and nonerythematous borders. Smaller ulcers may cluster and coalesce to form larger ulcers. Ulcers are generally very painful, involve the floor of the mouth and ventral surface of the tongue, resolve within 14 days, and generally leave no visible scar.

ETIOLOGY

Both hereditary and environmental causes may contribute to the disease process.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Behçet syndrome
- Mouth and genital ulcers with inflamed cartilage (MAGIC) syndrome
- Systemic lupus erythematosus
- Gluten-sensitive enteropathy
- Inflammatory bowel disease
- Human immunodeficiency virus infection
- Herpes simplex virus
- Cyclic neutropenia
- Periodic fever with aphthous stomatitis, pharyngitis, and adenitis (PFAPA)
- Hyperimmunoglobulin D syndrome
- Agranulocytosis
- Autoimmune bullous disease
- Oral erosive lichen planus
- Drug-induced mucosal ulcers

Table E1 summarizes the etiologies and differential diagnosis of recurrent aphthae.

WORKUP

- Clinical history: A detailed history includes associated illness, family history, the frequency of ulceration, number and size of ulcers, duration of the outbreak, and location of ulcers including non-oral lesions.

FIG. E1 Recurrent aphthous stomatitis. Minor aphthous ulcer. Shallow, creamy-white ulceration surrounded by an intensely red halo and located on non-keratinized mucosa, representing a classic presentation. (From Bolognia J et al: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.)

TABLE E1 Recurrent Aphthae—Etiologies and Differential Diagnosis

Etiologies

- Idiopathic (immune-mediated)
- Related to an underlying systemic disorder: Inflammatory bowel disease, systemic lupus erythematosus, HIV infection, Behçet syndrome, reactive arthritis*, cyclic neutropenia, PFAPA (*p*eriodic *f*ever, *a*phthous stomatitis, *p*haryngitis, and *a*denitis) syndrome, certain hereditary periodic fever syndromes (e.g., HIDS, NOMID)
- Possibly related to an underlying nutritional disorder (controversial): Vitamin B_{12}, folate, or iron deficiency

Differential Diagnosis

- Recurrent erosions and ulcerations due to an inflammatory disorder, e.g., erythema multiforme, fixed drug eruption, contact stomatitis: Less pain at onset, less peripheral erythema
- Recurrent herpes simplex viral infection: Only involves keratinized mucosa (hard palate, attached gingiva) in immunocompetent hosts.
- Trauma: Less pain at onset, less peripheral erythema, more ragged edges

HIDS, Hyperimmunoglobulinemia D with periodic fever syndrome; *HIV,* human immunodeficiency virus; *NOMID,* neonatal-onset multisystem inflammatory disease.
*Previously referred to as Reiter disease.
Modified from Bolognia J et al: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.

TABLE E2 Recurrent Aphthous Stomatitis (RAS) Subtypes

	Minor RAS	Major RAS	Herpetiform RAS
DESCRIPTION	Round or oval lesions with gray, white, or yellow bases and erythematous border	Round or oval lesions with gray, white, or yellow bases and erythematous border	Small, deep ulcers, may cluster and coalesce to form larger irregular shaped ulcers
LOCATION	Lips, cheeks, tongue, the floor of mouth	Lips, pharynx	Lips, cheeks, tongue, the floor of mouth
SIZE OF ULCERS	<10 mm	>10 mm	1-3 mm
NUMBER OF ULCERS	1-5	1-10	10-100
DURATION	4-14 days; without scarring	>4 wk; possible scarring	<4 wk; without scarring

TABLE E3 Therapeutic Ladder for Complex Aphthosis

Local therapy (agents may be used in combination)

Local anesthetics (2)
Superpotent topical corticosteroids (1*/2) or corticosteroid inhalers (2)
Intralesional corticosteroids (2)
Topical tacrolimus (3)

Systemic therapy

Colchicine (1†/2)
Dapsone (1†/2)
Combination of colchicine and dapsone (2)
Thalidomide (1)

Key to evidence-based support: (1) prospective controlled trial; (2) retrospective study or large case series; (3) small case series or individual case reports.
*Clobetasol propionate in an adhesive denture paste.
†In patients with Behçet syndrome.
Adapted from Letsinger JA et al: *J Am Acad Dermatol* 52:500-8, 2005, with permission. In Bolognia J et al: *Dermatology*, ed 4, Philadelphia, 2018, Elsevier.

- Physical examination: Aphthous ulcers are well-circumscribed small round or oval-shaped lesions with gray-white or yellow pseudomembranous bases with an erythematous halo. RAS may be further broken down into its subtypes as outlined in Table E2.
- RAS is generally a clinical diagnosis; however, if RAS is persistent, further laboratory testing may be considered.
- Biopsy: Typically not required; however, in more severe or persistent cases a biopsy may aid in ruling out other mucosal pathologies.

LABORATORY TESTS

If RAS is severe, persistent, or occurs at a later age of onset, it is reasonable to investigate further for other potential causes. Laboratory screening for other causes includes a complete blood count, inflammatory markers such as erythrocyte sedimentation rate and C-reactive protein, and nutritional deficiency markers such as serum B^{12}, folate, and iron.

IMAGING STUDIES

There are no imaging studies indicated in the workup of aphthous ulcers.

Rx TREATMENT

The exact cause of aphthous ulcers and RAS is still largely unknown, and the first-line treatment modalities are aimed at supportive care and speeding up healing time. Treatment is based on low-quality studies, and there are no curative pharmacological treatments. If aphthae are secondary to an underlying disease, treatment of the primary disease may reduce the duration of the aphthae. Treatment is a stepwise approach (Table E3) and includes good oral hygiene, avoiding trauma (e.g., biting lips or cheeks, oral hardware including braces) and known drug or food triggers, topical anesthetics, topical corticosteroids, topical antimicrobials, and systemic medications.

ACUTE GENERAL Rx

- Topical anesthetics: Can be used before eating for temporary relief
  1. 2% viscous lidocaine applied directly or used as "swish and spit."
  2. Diphenhydramine liquid (12.5 mg/5 ml): Use 5 ml as "swish and spit."
- Topical corticosteroids: First-line treatment for mild to moderate RAS
  3. Dexamethasone elixir (0.5 mg/5 ml): Take 5 ml, swish for 5 min before spitting out. Repeat three to four times daily.
- Topical antimicrobial: Not typically necessary in mild cases but may be beneficial in preventing secondary infection in more severe cases or cases involving other immunosuppressive medications
  1. Chlorhexidine 0.12% mouth rinse: Use 15 ml as "swish and spit" twice daily.
  2. Nystatin suspension: "Swish and swallow" four times daily.

CHRONIC Rx

Oral options may be tried in patients reporting no benefit with topical treatment alone or in case of severe RAS.

- Oral prednisone 20 mg to 40 mg daily for 4 to 7 days is typically the first-line treatment of acute severe RAS.
- Montelukast 10 mg daily may be a safe alternative when severe RAS is not well controlled with oral corticosteroids.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Ascorbic acid 2000 mg/day may be considered as an adjunct to topical therapy in managing minor RAS.
- Zinc 50 mg/day may also be beneficial in wound healing.

NONPHARMACOLOGIC THERAPY

Laser therapy or chemical cauterization have been cited as an adjunct to the above therapies to help reduce acute pain; however, their ability to prevent recurrent episodes of aphthae is still unknown.

DISPOSITION

Although a painful condition, aphthous ulcers and RAS are generally self-resolving with an average healing time of 2 wk and carry an excellent prognosis. Consider an alternative etiology if the patient exhibits systemic symptoms or has other pertinent past medical history.

REFERRAL

Referral to a specialist is recommended if an alternative diagnosis is more likely. Severe or persistent cases of RAS may be referred to dermatology.

PREVENTION

Practice good oral hygiene.

PATIENT & FAMILY EDUCATION

Educate patients and parents of pediatric patients on pain control with the use of topical anesthetics before eating or drinking to prevent dehydration. Topical pain control is also beneficial before performing basic dental hygiene. Avoid citrus juices and spicy or salty foods. Educate regarding return precautions including worsening pain, the spread of ulcers (especially beyond oral mucocutaneous membranes), fever, decreased fluid intake, or other systemic symptoms.

Appendicitis PTG

BASIC INFORMATION

DEFINITION

Appendicitis is the acute inflammation of the vermiform appendix.

ICD-10CM CODES

K35.2	Acute appendicitis with generalized peritonitis
K35.3	Acute appendicitis with localized peritonitis
K35.80	Unspecified acute appendicitis
K35.89	Other acute appendicitis
K36	Other appendicitis
K37	Unspecified appendicitis

EPIDEMIOLOGY & DEMOGRAPHICS

- Appendicitis occurs in 10% of the population, most commonly between the ages of 10 and 30 yr. Median age is 22 yr. Lifetime risk is 7% to 14%.
- Approximately 300,000 appendectomies are performed in the U.S. each yr.
- It is the most common abdominal surgical emergency.
- Incidence of appendicitis has declined over the past 30 yr.
- Male:female ratio is 3:2 until mid-20s; it equalizes after age 30 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- In children with abdominal pain, fever is the single most useful sign associated with appendicitis. Vomiting, rectal tenderness, and rebound tenderness along with fever are more indicative of appendicitis in children than in adults.
- Abdominal pain: Initially the pain may be epigastric or periumbilical in nearly 50% of patients; it subsequently localizes to the right lower quadrant within 12 to 18 hr. Pain can be found in back or right flank if appendix is retrocecal or in other abdominal locations if there is malrotation of the appendix.
- Pain with right thigh extension *(psoas sign),* low-grade fever: Temperature may be >38° C if there is appendiceal perforation.
- Pain with internal rotation of the flexed right thigh *(obturator sign)* is present.
- Right lower quadrant (RLQ) pain on palpation of the left lower quadrant (LLQ) *(Rovsing sign):* Physical examination may reveal right-sided tenderness in patients with pelvic appendix.
- Point of maximum tenderness is in the RLQ *(McBurney point).*
- Nausea, vomiting, tachycardia, cutaneous hyperesthesias at the level of T12 can be present.

ETIOLOGY

Obstruction of the appendiceal lumen with subsequent vascular congestion, inflammation, and edema; common causes of obstruction are:

- Fecaliths: 30% to 35% of cases (most common in adults)
- Foreign body: 4% (fruit seeds, pinworms, tapeworms, roundworms, calculi)
- Inflammation: 50% to 60% of cases (submucosal lymphoid hyperplasia [most common etiology in children, teens])
- Neoplasms: 1% (carcinoids, metastatic disease, carcinoma)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Intestinal: Regional cecal enteritis, incarcerated hernia, cecal diverticulitis, intestinal obstruction, perforated ulcer, perforated cecum, Meckel diverticulitis
- Reproductive: Ectopic pregnancy, ovarian cyst, torsion of ovarian cyst, salpingitis, tuboovarian abscess, mittelschmerz, endometriosis, seminal vesiculitis
- Renal: Renal and ureteral calculi, neoplasms, pyelonephritis
- Vascular: Leaking aortic aneurysm
- Psoas abscess
- Trauma
- Cholecystitis
- Mesenteric adenitis
- Table 1 summarizes the differential diagnosis of appendicitis

WORKUP

Patients with RLQ pain, nausea, vomiting, anorexia, and RLQ rebound tenderness should undergo prompt clinical and laboratory evaluation. Imaging studies are generally not necessary in typical appendicitis and generally reserved for patients with an equivocal likelihood of appendicitis. They are useful when the diagnosis is uncertain. Laparoscopy may be useful as both a diagnostic and a therapeutic modality.

LABORATORY TESTS

- Complete blood count with differential reveals leukocytosis with a left shift in 90% of patients with appendicitis. Total white blood cell (WBC) count is generally lower than 20,000/mm^3. Higher counts may be

TABLE 1 Differential Diagnosis of Appendicitis

Diagnosis	Findings That Help Differentiate Entity from Appendicitis
Bacterial or viral enteritis	Nausea, vomiting, and diarrhea are severe; pain usually develops after vomiting.
Epiploic appendagitis	Focal abdominal pain and tenderness without migration or progression of the pain; patients have a paucity of other GI symptoms such as anorexia or nausea. Laboratory findings are usually normal.
Mesenteric adenitis	Duration of symptoms is longer; fever is uncommon; RLQ physical findings are less marked; WBC count is usually normal.
Pyelonephritis	Pain is more likely to be felt in the right flank; high fever and rigors are common; marked pyuria or bacteriuria and urinary symptoms are present; abdominal rigidity is less marked.
Renal colic	Pain radiates to the right groin; significant hematuria; character of the pain is clearly colicky.
Acute pancreatitis	Pain and vomiting are more severe; tenderness is less well localized; serum amylase and lipase levels are elevated.
Crohn disease	History of recurrent similar attacks; diarrhea is more common; palpable mass is more common; extraintestinal manifestations may have occurred or be present.
Cholecystitis	History of prior attacks is common; pain and tenderness are greater; radiation of pain is to the right shoulder; nausea is more marked; liver biochemical tests are more likely to be abnormal.
Meckel diverticulitis	Nearly impossible to distinguish preoperatively from appendicitis.
Cecal diverticulitis	Difficult to distinguish preoperatively from appendicitis; symptoms are milder and of longer duration; CT is helpful; patients are usually older.
Sigmoid diverticulitis	Usually occurs in older patients; changes in bowel habits are more common; radiation of the pain is to the suprapubic area, not RLQ; fever and WBC count are higher.
Small bowel obstruction	History of abdominal surgery; pain is colicky; vomiting and distention are more marked; RLQ localization is uncommon.
Ectopic pregnancy	History of menstrual irregularities; characteristic progression of symptoms is absent; syncope; positive pregnancy test.
Ruptured ovarian cyst	Occurs in the middle of the menstrual cycle; pain is of sudden onset; nausea and vomiting are less common; WBC count is normal.
Ovarian torsion	Vomiting is more marked and occurs at the same time as the pain; progression of symptoms is absent; abdominal or pelvic mass often is palpable.
Acute salpingitis or tuboovarian abscess	Longer duration of symptoms; pain begins in the lower abdomen; often there is a history of STDs; vaginal discharge and marked cervical tenderness often are present.

CT, Computed tomography; *GI,* gastrointestinal; *IV,* intravenous; *RLQ,* right lower quadrant; *STD,* sexually transmitted disease; *WBC,* white blood cell.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

indicative of perforation. Less than 4% have a normal WBC and differential. A WBC count <10,000/mm^3 decreases the likelihood of appendicitis. Low hemoglobin and hematocrit levels in an older patient should raise suspicion for gastrointestinal tract carcinoma.
- Microscopic hematuria and pyuria may occur in <20% of patients.
- Human chorionic gonadotropin to rule out pregnancy in females of reproductive age.

IMAGING STUDIES

- Multidetector computed tomography (Fig. E1) is a useful test for routine evaluation of suspected appendicitis in adults. CT of the abdomen/pelvis without contrast has a sensitivity of >90% and an accuracy >94% for acute appendicitis. A distended appendix, periappendiceal inflammation, and a thickened appendiceal wall are indicative of appendicitis. Table 2 describes CT findings of appendicitis. In children and young adults, exposure to CT radiation is of particular concern. Trials with low-dose CT (116 mGy cm) have shown that low-dose CT is not inferior to standard-dose CT (521 mGy cm) with respect to negative (unnecessary) appendectomy rates in young adults with suspected appendicitis.
- Ultrasonography (Fig. E2) has a sensitivity of 75% to 90% for the diagnosis of acute appendicitis, although it is highly operator dependent and difficult in patients with large body habitus. Ultrasound is useful, especially in pregnancy and in younger women when diagnosis is unclear. Normal ultrasonographic findings should not deter surgery if the history and physical examination are indicative of appendicitis.
- MRI of the abdomen and pelvis can also be used to accurately diagnose acute appendicitis in pregnant patients (100% sensitivity, 93.6% specificity) without exposure to ionizing radiation.

TABLE 2 Computed Tomography Findings of Appendicitis: SCALPEL Mnemonic

Term	Description
Stranding	Fat stranding suggests regional inflammation, possibly because of appendicitis.
Cecum	The appendix originates from the cecum, which should be identified first to help localize the appendix. The cecum may show wall thickening, suggesting appendicitis.
Air	Air outside of the lumen of the appendix is pathologic and suggests perforation. Air within the appendiceal wall is also abnormal.
Large	The normal appendix is <6 mm; an enlarged appendix >6 mm suggests appendicitis. Wall thickening >1 mm also suggests appendicitis.
Phlegmon	Inflammatory changes surrounding the appendix suggest a perforated appendix. A heterogeneous collection called a phlegmon may be seen. If the appendix has ruptured, a pericecal phlegmon may be the only remaining evidence, because the appendix itself may not be seen.
Enhancement	The wall of an abnormal appendix enhances with IV contrast and appears brighter than the normal bowel or the normal psoas muscle.
Lith	An appendicolith is a calcified stone sometimes found in the lumen of an inflamed appendix.

IV, Intravenous.
From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Nothing by mouth
- Do not administer analgesics until the diagnosis is made

ACUTE GENERAL Rx

- Urgent appendectomy (laparoscopic or open), correction of fluid and electrolyte imbalance with vigorous IV hydration, and electrolyte replacement
- IV antibiotic prophylaxis to cover gram-negative bacilli and anaerobes (ampicillin/sulbactam 3 g IV q6h or piperacillin/tazobactam 4.5 g IV q8h in adults)

PEARLS & CONSIDERATIONS

COMMENTS

- Perforation is common (20% in adult patients). Indicators of perforation are pain lasting >24 hr, leukocytosis >20,000/mm^3, temperature >102° F (38.9° C), palpable abdominal mass, and peritoneal findings.
- In general, prognosis is excellent. Mortality rate is <1% in young adults without complications; however, it exceeds 10% in elderly patients with ruptured appendix.
- In approximately 20% of patients who undergo exploratory laparotomy because of suspected appendicitis, the appendix is normal.
- An increasing amount of evidence supports the use of antibiotics instead of surgery for treating patients with uncomplicated appendicitis. A trial assessing the feasibility of nonoperative management for uncomplicated acute appendicitis in children using either IV piperacillin-tazobactam or ciprofloxacin metronidazole therapy for at least 24 hours followed by oral antibiotics for 10 days revealed that 90% of children managed nonoperatively had no progression within 30 days.[1] Another trial among patients with CT-proven, uncomplicated appendicitis revealed that antibiotic treatment did not meet the prescribed criterion for noninferiority compared with appendectomy. Most patients randomized to antibiotic treatment for uncomplicated appendicitis did not require appendectomy during the 1-yr follow-up period, and those who required appendectomy did not experience significant complications.[2] A 5-yr follow-up of antibiotic therapy for uncomplicated acute appendicitis in the APPAC randomized clinical trial revealed that among patients who were initially treated with antibiotics for uncomplicated acute appendicitis, the likelihood of late recurrence within 5 yr was 39.1%.[3] It remains to be determined whether the benefits of potentially avoiding an operation with antibiotics-first approach are outweighed by the burden to the patient related to future appendicitis episodes, more days of antibiotic therapy, lingering symptoms, and uncertainty that may affect quality of life.[4]

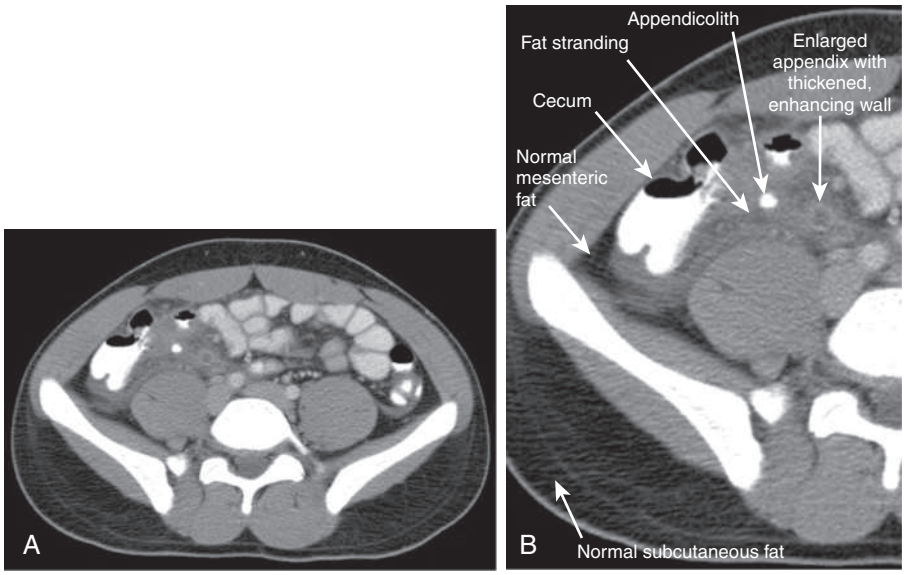

FIG. E1 Appendicitis, computed tomography (CT) with intravenous and oral contrast. This CT demonstrates classic findings of appendicitis in an 18-year-old male with right lower quadrant pain, as seen with CT with IV and oral contrast. Studies suggest that CT without contrast has similar sensitivity and specificity. An enlarged appendix is seen near the cecum as a right lower quadrant tubular structure in short-axis cross section, giving it a circular appearance. The surrounding fat shows stranding, a smoky appearance indicating inflammation (compare with normal mesenteric and subcutaneous fat, which is nearly black). The appendiceal wall shows enhancement, a brightening after administration of IV contrast. This slice also shows an appendicolith, an occasional finding of appendicitis. It does not appear to be within the appendix in this slice, because the appendix bends in and out of the plane of this slice. An appendicolith usually appears as a calcified (white) rounded structure, visible without any contrast. **A,** Axial CT image. **B,** Close-up. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.)

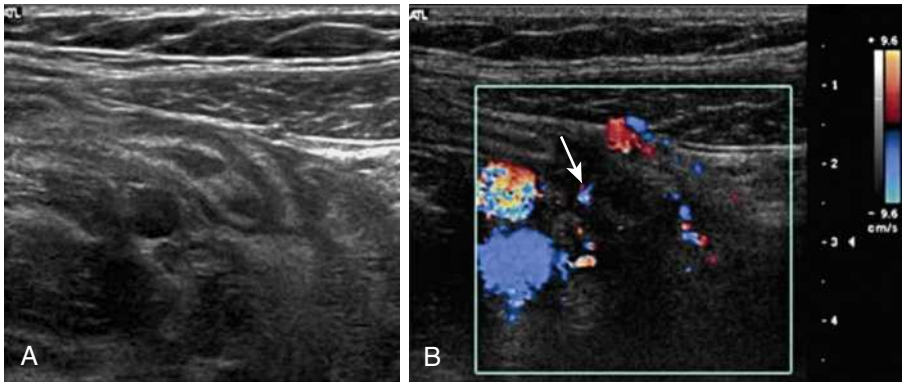

FIG. E2 Appendicitis. A, Transabdominal ultrasound using a linear transducer vdemonstrates a thick, tubular, noncompressible structure. **B,** Same imaging method with addition of color Doppler ultrasound shows increased vascularity within the luminal wall consistent with inflammation *(arrow).* (From Fielding JR et al: *Gynecologic imaging,* Philadelphia, 2011, Saunders.)

Arrhythmogenic Right Ventricular Dysplasia ALG

BASIC INFORMATION

DEFINITION

Arrhythmogenic right ventricular dysplasia (ARVD) is a cardiomyopathy characterized by replacement of the normal myocardium with fibrofatty tissue, mainly of the right ventricle but also occasionally with involvement of the left ventricle. It is defined clinically by palpitations and syncope and potentially life-threatening ventricular arrhythmias.

SYNONYMS

Arrhythmogenic right ventricular cardiomyopathy
ARVC

ICD-10CM CODE
I42.8 Arrhythmogenic ventricular dysplasia

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: 1:2000 to 5000 persons. It is one of the leading causes of arrhythmic cardiac arrest in young people and athletes.
PREDOMINANT SEX AND AGE: Mean age, 31 yr (range, 12 to 50 yr), predominantly male
RISK FACTORS: Family history of ARVD (present in nearly 50% of affected patients)
GENETICS:

- Autosomal dominant (most common) with variable penetrance and polymorphic phenotypic expression
- Autosomal recessive (rarely, e.g., Naxos disease)
- Several different gene mutations in desmosomal proteins
- Gene mutations can be identified in 50% of affected individuals

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- ARVD can present with palpitations, syncope, and chest discomfort and less commonly sudden cardiac arrest and signs of right ventricular failure such as dyspnea, edema, and fatigue. Patients may be clinically asymptomatic for many yrs.
- Cardiac arrest after physical exertion may be the initial presentation.
- Physical examination will be normal in most patients. Widely split S2 is an important diagnostic clue.

ETIOLOGY

ARVD is characterized by progressive replacement of mainly the right ventricular myocardium with fibrofatty tissue after apoptotic myocardial cell death caused by mutations of desmosomal protein.

DIAGNOSIS

A major criterion equals 2 points; a minor criterion equals 1 point. The diagnosis of ARVD is considered definite if the patient has 4 points and probable with 3 points. See Table 1 for diagnostic criteria.

DIFFERENTIAL DIAGNOSIS

- Cardiomyopathy with involvement of the right ventricle
- Uhl anomaly: Rare anomaly that presents mainly in childhood with signs and symptoms of right heart failure and characterized by a paper-thin right ventricle resulting from death of the myocytes throughout the right ventricle
- Idiopathic RV tachycardia
- Sarcoidosis
- Right ventricular infarction

WORKUP

- Initial workup includes history with focus on sudden death in the family, resting ECG, 24-Holter ECG, signal-averaged ECG, and imaging studies with echocardiography and MRI.
- ECG will have diagnostic findings in 50% to 90% of patients with ARVD, including T-wave inversions in anterior precordial leads V_1 to V_6, epsilon waves, and a QRS duration longer than 110 ms in V1 or >40 ms longer in V1 than V6 (Fig. 1).
- Ventricular tachycardia (VT) with left bundle branch block pattern and frequent PVCs (>500 in 24 h) might be detected by 24-hr Holter monitoring.
- An abnormal signal-averaged ECG is a minor diagnostic criteria.
- Echocardiography will show right ventricular dilation with regional wall motion abnormalities, aneurysms, and depressed RV function that varies with the severity of the disease.
- MRI (Fig. 2) is a noninvasive method to detect structural abnormalities (fibrofatty changes) and regional dysfunction. Cardiac MRI (CMR) is the most sensitive method to detect ARVD, but it has high false-positive rates. Cardiac CT angiogram (Fig. E3) will reveal thinning and aneurysmal dilation of the RV anterior wall and outflow tract.
- If the routine tests are not conclusive, endomyocardial biopsy and electrophysiologic testing can be considered. However, biopsies and radionuclide ventriculography are rarely performed in the U.S.

TREATMENT

No curative treatment is available. The treatment goal is focused on preventing sudden cardiac death, symptomatic treatment of right heart failure, and pharmacologic and invasive treatment of arrhythmias. Therapy with cardio-selective beta-blockers is recommended. Family members with a negative phenotype (either healthy gene carriers or those with an unknown genotype) do not need any specific treatment other than sports restriction; however, lifelong clinical assessment with the use of noninvasive tests at least every 2 yr is warranted.[1]

NONPHARMACOLOGIC THERAPY

- Avoidance of activity that may trigger ventricular tachycardia and may lead to disease progression.
- ICD implantation needs to be considered in patients who have the definite diagnosis of ARVD. Patients with unexplained syncope, advanced disease, documented ventricular arrhythmias, or a family history of sudden cardiac death or who have been resuscitated from cardiac arrest are at high risk. A subcutaneous ICD might be an alternative option instead of transvenous implantation.
- Radiofrequency catheter ablation is used in cases of refractory VT or frequent tachycardia after defibrillator placement.
- Cardiac transplantation.
- Fig. 4 describes a management algorithm for ARVD.

PHARMACOLOGIC TREATMENT

Antiarrhythmic therapy with sotalol (first-line treatment) or amiodarone, often in combination with beta-blockers, is used for tachycardia suppression.

REFERRAL

- Early cardiology and electrophysiology referral
- Consider referring for genetic counseling

PEARLS & CONSIDERATIONS

PREVENTION

All first-degree relatives should be tested if ARVD is confirmed. Sports activity increases the risk of sudden cardiac death among adolescents and young adults with ARVC. The estimated overall mortality ranges from 0.08% to 3.6% per yr.

[1]Corrado D et al: Arrhythmogenic right ventricular cardiomyopathy, *N Engl J Med* 376:61-72, 2017.

TABLE 1 Global or Regional Dysfunction and Structural Alterations

Major

2D echo criteria

Regional RV akinesia, dyskinesia, or aneurysm and one of the following measured at end diastole:

PLAX RVOT ≥32 mm or

PSAX RVOT ≥36

Fractional area change ≤33%

MRI criteria

Regional RV akinesia or dyskinesia or dyssynchronous RV contraction and one of the following:

Ratio of RV end-diastolic volume to BSA >100, <110 ml/m^2 (male) or >100 ml/m^2

RV ejection fraction >40% ≤45%

RV angiography criteria

Regional RV akinesia, dyskinesia, or aneurysm

Minor

2D echo criteria

Regional RV akinesia or dyskinesia or dyssynchronous RV contraction and one of the following measured at end diastole:

PLAX RVOT ≥29 <32 mm or

PSAX RVOT ≥32 <36

Fractional area change >33% ≤40%

MRI criteria

Regional RV akinesia or dyskinesia or dyssynchronous RV contraction and one of the following:

Ratio of RV end-diastolic volume to BSA ≥110 ml/m^2 (male) or ≥100 ml/m^2

RV ejection fraction ≤40%

Tissue characterization of wall

Major

Residual myocytes <60% by morphometric analysis (or <50% if estimated) with fibrous replacement of the RV free wall myocardium in >1 sample, with or without fatty replacement of tissue on endomyocardial biopsy

Minor

Residual myocytes 60%-75% by morphometric analysis (or 50%-65% if estimated), with fibrous replacement of the RV free wall myocardium in >1 sample with or without fatty replacement of tissue on endomyocardial biopsy

Repolarization abnormalities

Major

Inverted T waves in right precordial leads (V1, V2, and V3) or beyond in individuals >14 y of age (in the absence of complete RBBB QRS ≥120 ms)

Minor

Inverted T waves in V1 and V2 in individuals >14 y of age (in the absence of complete RBBB) or in V4, V5, and V6

Inverted T waves in leads V1, V2, V3, and V4 in individuals >14 y of age in the presence of a complete RBBB

Depolarization or conduction abnormalities

Major

Epsilon wave (reproducible low-amplitude signals between end of QRS complex to onset of T wave) in the right precordial leads (V1-V3)

Minor

Late potentials by SAECG in ≥1 of 3 parameters in the absence of a QRSd of ≥110 ms on standard ECG

Filtered QRS ≥114 ms

Duration of terminal QRS <40 mV ≥38 ms

Root-mean-square voltage of terminal 40 ms ≤20 μV

Terminal activation duration ≥55 ms measured from the nadir of the end of the QRS, including R', in V1, V2, or V3 in absence of complete RBBB

Arrhythmias

Major

Nonsustained or sustained VT of LBBB morph with superior axis

Minor

Nonsustained or sustained VT of RVOT configuration, LBBB morph with inferior axis or of unknown axis

>500 PVCs per 24 hr (Holter)

Family history

Major

ARVD/C in first-degree relative who meets Task Force criteria

ARVD/C confirmed pathologically at autopsy or surgery in first-degree relative

Identification of pathogenic mutation categorized as associated or probably associated with ARVD/C in the patient under evaluation

Minor

History of ARVD/C in first-degree relative in whom it is not possible to determine whether the family member meets Task Force criteria

Premature sudden death (<35 yr of age) caused by suspected ARVD/C in a first-degree relative

ARVD/C confirmed pathologically or by current Task Force criteria in second-degree relative

A major criterion equals 2 points, a minor criterion 1 point. BASIC INFORMATION

DEFINITION

Asbestosis is a slow, progressive diffuse interstitial fibrosis as a consequence of dose-related inhalation exposure to fibers of asbestos in miners, millers, workers of asbestos textiles, and insulators. Clinically, the lung involvement is characterized by bilateral diffuse interstitial fibrosis, more pronounced in the lower lobes, and pleural thickening, leading to shortness of breath and dry cough.

Asbestos exposure can lead to the spectrum of pulmonary pathology, including pulmonary fibrosis; asbestos-related pleural plaque (ARPD), both focal and diffuse; and malignancies (small cell carcinoma, non–small cell carcinoma, or mesothelioma).

ICD-10CM CODE

J61 Pneumoconiosis due to asbestos and other mineral fibers

EPIDEMIOLOGY & DEMOGRAPHICS

- Five to 10 new cases per 100,000 persons per yr in the U.S.
- Prolonged interval (20 to 30 yr) between exposures to inhaled fibers and clinical manifestations of disease.
- Most common in workers over age 40 yr involved in the primary extraction of asbestos from rock deposits and in those involved in the fabrication and installation of products containing asbestos (e.g., naval shipyards in World War II; installation of floor tiles, ceiling tiles, acoustic ceiling coverings, wall insulation, and pipe coverings in public buildings).
- Smokers and heavy drinkers have the greatest risk of developing this disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Insidious onset of shortness of breath and dry cough with exertion is usually the first sign of asbestosis.
- Dyspnea becomes more severe as the disease advances; with time, progressively less exertion is tolerated.
- Cough is frequent and usually paroxysmal, dry, and nonproductive. Hemoptysis is rare but reported.
- Scant mucoid sputum may accompany the cough in the later stages of the disease.
- Fine end-respiratory crackles (rales, crepitations) are heard more predominantly in the lung bases.
- Digital clubbing, edema, jugular venous distention are present.
- Advanced cases may have signs of right heart failure.

ETIOLOGY/PATHOGENESIS

Inhalation of asbestos fibers. The pathogenesis of pulmonary interstitial inflammation and fibrosis is related to immune mechanisms. Asbestosis is known to be associated with positive serum antinuclear antibody (ANA) and rheumatoid factor (RF). Recently, an important role of interleukin-1beta (IL-1beta) in the pathogenesis of asbestosis and its systemic autoimmune manifestations have been reported.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Silicosis
- Siderosis, other pneumonoconioses
- Lung cancer
- Atelectasis

WORKUP

Documentation of exposure history, diagnostic imaging, pulmonary function testing

LABORATORY TESTS

- Generally not helpful
- Possible mild elevation of erythrocyte sedimentation rate (ESR), positive antinuclear antibody (ANA), and rheumatoid factor (RF) (these tests are nonspecific and do not correlate with disease severity or activity)
- Pulmonary function testing: With decreased vital capacity (VC), decreased total lung capacity (TLC), decreased carbon monoxide gas transfer (DLco)
- FEV1 might be reduced in concomitant smokers
- Arterial blood gases: Hypoxemia, hypercarbia in advanced stages

IMAGING STUDIES

- Chest radiograph (Fig. E1):
  1. Small, irregular shadows in lower lung zones.
  2. The imaging findings vary from benign pleural disease (including discrete plaques, pleural calcification, diffuse pleural thickening with blunting of costophrenic angles, and thickening of the interlobar fissure) to asbestosis (diffuse interstitial pulmonary fibrosis.
- Thickened pleura, calcified plaques (present under diaphragm and lateral chest wall).
- CT scan of chest (Fig. E2) confirms diagnosis. Typical findings on high-resolution CT of the chest include increased interstitial markings found mainly at the bases (Fig. E3). As the disease progresses, honeycombing is noted.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Smoking cessation, proper nutrition, exercise program to maximize available lung function
- Home oxygen therapy PRN
- Removal of patient from further asbestos fiber exposure

GENERAL Rx

- Prompt identification and treatment of respiratory infections
- Supplemental oxygen on a PRN basis
- Annual influenza vaccination, pneumococcal vaccination every 6 yr
- Pulmonary rehabilitation can be considered in advanced cases for improved cardiopulmonary capacity
- Some new data are coming out targeting IL-1 beta therapy on the progression of lung fibrosis that suggest a new perspective for the treatment of systemic autoimmune features of asbestosis and, possibly, of lung involvement.[1]

DISPOSITION

- There is no specific treatment for asbestosis.
- Death is usually from respiratory failure from cor pulmonale.
- Diffuse pleural thickening and asbestosis are associated with increased risks of malignant peritoneal mesothelioma beyond the risk calculated to be associated with the degree of asbestos exposure.[2]
- None of the benign pleural diseases or ARPD was associated with an increased risk of malignant pleural mesothelioma.
- Asbestos increases the risk for development of lung cancer regardless of smoking status. In patients with diffuse parenchymal disease secondary to asbestos, the risk of lung cancer is nearly 40 times higher than in those with no history of smoking.
- Asbestos exposure without asbestosis and smoking increases the risk of lung cancer. The joint effect of asbestos and smoking is additive and depends in part on the presence of asbestosis. Asbestos workers who stop smoking experience a dramatic decline in lung cancer risk, which approaches that of nonsmokers after 30 yr.
- Low-dose chest CT scanning offers an excellent opportunity to detect early-stage lung cancers in asbestos-exposed workers.
- Computed tomography is more sensitive than radiography, computed tomography without contrast generally suffices for evaluation, and PET scan (fluorodeoxyglucose-positron emission tomography) may have utility in patients with mesothelioma.
- Survival in patients after development of mesothelioma is 4 to 6 yr.

BASIC INFORMATION

DEFINITION

Ascariasis is a parasitic infection caused by the nematode *Ascaris lumbricoides.* The majority of those infected are asymptomatic; however, clinical disease may arise from pulmonary hypersensitivity, intestinal obstruction, or nutrient depletion and other secondary complications.

SYNONYMS

Round worms
Worms

ICD-10CM CODES

B77.0	Ascariasis with intestinal complications
B77.81	Ascariasis pneumonia
B77.89	Ascariasis with other complications
B77.9	Ascariasis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- Unknown. Worldwide, *A. lumbricoides* is the most common helminthic infection of humans, infecting as many as 1 billion or more persons. 71% of persons at risk for infection live in Asia and the Western Pacific.
- Three times the infection rates found in blacks as in whites.

PREVALENCE (IN U.S.): Estimated at 4 million, the majority of which live in the rural southeastern part of the country; ascariasis is associated with poor sanitation

PREDOMINANT SEX: Both sexes probably equally affected, with a possible slight female preponderance

PREDOMINANT AGE: Most common in children from ages 2 to 10 yr old and decreases after age 15; infections tend to cluster in families

PEAK INCIDENCE: Unknown

NEONATAL INFECTION: Probable transmission, though not specifically studied

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most people infected with *Ascaris* are asymptomatic
- Occurs approximately 9 to 12 days after ingestion of eggs (corresponding to the larval migration through the lungs)
- Nonproductive cough
- Substernal chest discomfort
- Fever
- In patients with large worm burdens, especially children, intestinal obstruction associated with perforation, volvulus, and intussusception
- Migration of worms into the biliary tree giving clinical appearance of biliary colic and pancreatitis as well as acute appendicitis with movement into that appendage
- Rarely, infection with *A. lumbricoides* producing interstitial nephritis and acute renal failure
- In endemic areas in Asia and Africa, malabsorption of dietary proteins and vitamins as a consequence of chronic worm intestinal carriage; 1 billion people worldwide are infected with this nematode

ETIOLOGY

- Transmission is usually hand to mouth, but eggs may be ingested via transported vegetables grown in contaminated soil.
- Eggs are hatched in the small intestine, with larvae penetrating intestinal mucosa and migrating via the circulation to the lungs.
- Larval forms proceed through the alveoli, ascend the bronchial tree, and return to the intestines after swallowing, where they mature into adult worms.
- Estimated time until the female adult worm begins producing eggs is 2 to 3 mo.
- Eggs are passed out of the intestines with feces and can survive for years in warm, moist, shaded soil.
- Within human host, adult worm life span is 1 to 2 yr.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Radiologic manifestations and eosinophilia to be distinguished from drug hypersensitivity and Löffler syndrome.
- Table E1 compares features of major intestinal nematodes.

LABORATORY TESTS

- Examination of the stool for *Ascaris* ova (Fig. E1)
- The World Health Organization (WHO) recommends the Kato-Katz thick smear kit for soil-transmitted helminths
- Expectoration or fecal passage of adult worm
- Adult male worms: 10 to 30 cm long; adult female worms: Larger than male, up to 40 cm
- Eosinophilia: Most prominent early in the infection and subsides as the adult worm infestation established in the intestines; usually in 5% to 12% range but can be up to 50%
- Serology: Patients develop immunoglobulin G (IgG) antibodies, but they cross react with antigens from other helminths and are not protective; thus, serology is used more for epidemiologic purposes than for individual diagnosis
- Polymerase chain reaction (PCR) on stool samples; multiplex PCR can differentiate multiple different parasite species (*A. lumbricoides, T. trichiura,* and *N. americanus*)

IMAGING STUDIES

- Chest x-ray to reveal bilateral oval or round infiltrates of varying size (Löffler syndrome); NOTE: Infiltrates are transient and eventually resolve.
- Plain films of the abdomen and contrast studies to reveal worm masses in loops of bowel.
- Ultrasonography and endoscopic retrograde cholangiopancreatography (ERCP) to identify worms in the pancreaticobiliary tract.
- CT scan with oral contrast can also assist in the detection of GI foreign bodies such as parasites.

TREATMENT

NONPHARMACOLOGIC THERAPY

Aggressive IV hydration, especially in children with fever, severe vomiting, and resultant dehydration

ACUTE GENERAL Rx

- All infected patients, including asymptomatic ones, should be treated.
  1. Albendazole: 400 mg PO × 1 dose is the first-line agent
  2. Mebendazole 100 mg PO bid × 3 days for persons >1 yr of age or mebendazole 500 mg PO × 1 dose for persons >1 yr of age (not available as 500 mg in the U.S.)
- Cure rate with these agents is 95% to 100%, but they are contraindicated in pregnancy.
- Side effects: GI discomfort, headache, and rarely leukopenia
- Alternative agent or for use in pregnancy: Pyrantel pamoate (Antiminth)
  1. Given at a dose of 11 mg/kg PO (maximum dose of 1 g/day)
  2. Considered safe for use in pregnant women
- Other alternative agents:
  1. Ivermectin: 150 to 200 mcg/kg orally once
  2. Nitazoxanide: Ages 2 to 3 yrs: 100 mg/5 ml bid × 3 days, and ages 4 to 11 yrs: 200 mg/10 ml bid × 3 days. Cure rates in heavy worm burden are only 50% to 80%
  3. Piperazine citrate: No longer first-line agent due to toxicity but still used in cases of intestinal or biliary obstruction, as drug paralyzes the worm, helping its expulsion. Dose: 50 to 75 mg/kg once daily up to maximum of 3.5 g for 2 days
  4. Levamisole: 2.5 mg/kg once orally is recommended by the WHO as alternative therapy, but not available in the U.S.
- Complete obstruction should be managed surgically.

DISPOSITION

Overall prognosis is good. Patients should be reevaluated in 2 to 3 mo. Reinfection is common.

REFERRAL

- To gastroenterologist in cases of visualized pancreaticobiliary tract or appendiceal obstruction

- To surgeon in cases of complete obstruction or suspected secondary complication (e.g., perforation or volvulus)

PEARLS & CONSIDERATIONS

COMMENTS

- Hepatic abscess, containing both viable and dead worms, complicating *Ascaris*-induced biliary duct disease has been documented.
- Given the known transmission of the parasite, routine hand washing with soap and proper disposal of human waste would significantly decrease the prevalence of this disease.
- Other protective measures to avoid ingestion of worm eggs:
  1. Peel or cook food.
  2. Boil drinking water.
  3. Do not place small children directly on soil.

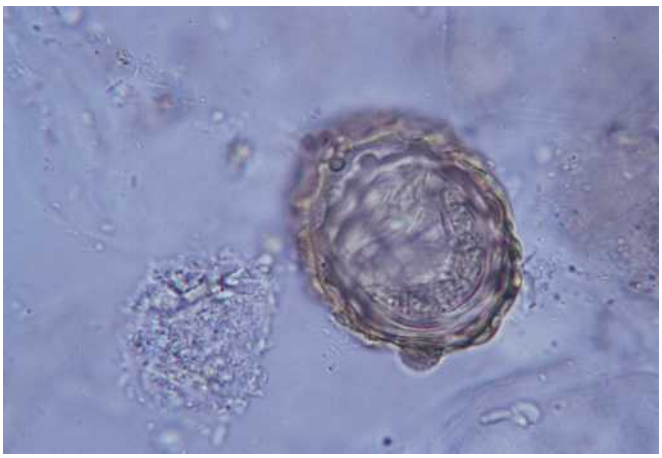

FIG. E1 ***Ascaris lumbricoides*** **ovum in feces.** The ovum measures 50 to 70 mm × 40 to 50 mm and is elliptical. The rough albuminous coat gives it a mammillated appearance. (From Cohen J, Powderly WG: *Infectious diseases*, ed 2, St Louis, 2004, Mosby.)

BASIC INFORMATION

DEFINITIONS

Ascites refers to a pathologic accumulation of fluid in the peritoneal cavity, most commonly caused by liver cirrhosis.

- **Diuretic-resistant ascites:** Ascites that cannot be mobilized or the early recurrence of which cannot be prevented because of lack of response to dietary sodium restriction and maximal doses of diuretics.
- **Diuretic-intractable ascites:** Ascites that cannot be mobilized or the early recurrence of which cannot be prevented because of the development of diuretic-induced complications that precludes the use of effective doses of diuretics.

SYNONYMS

Peritoneal cavity fluid
Hydroperitoneum
Hydroperitonia
Hydrops abdominis

ICD-10CM CODES

R18	Ascites
C78.6	Malignant ascites
K70.11	Alcoholic hepatitis with ascites
K70.31	Alcoholic cirrhosis of liver with ascites
K71.51	Toxic liver disease with chronic active hepatitis with ascites
R18.8	Other ascites

EPIDEMIOLOGY & DEMOGRAPHICS

Ascites is the most common complication of cirrhosis and signifies decompensation of chronic liver disease. Ascites occurs at a rate of 7% to 10% annually in cirrhotic patients. Ascites occurs in ~60% of individuals with cirrhosis within 10 yr of diagnosis. Cirrhosis is the cause of 85% of cases of ascites.

CLINICAL PRESENTATION & PHYSICAL FINDINGS

- Important information to elicit within history:
  1. History of viral hepatitis
  2. Alcoholism
  3. Intravenous drug use, intranasal cocaine use
  4. Sexual history (i.e., men who have sex with men)
  5. History of transfusions, tattoos, piercings, imprisonment
  6. Travel history and time spent in endemic regions for hepatitis
  7. Symptoms suggestive of peritoneal malignancy (e.g., weight loss, pain, palpable masses, rectal/vaginal bleeding)
  8. Other liver disease symptoms (e.g., increasing abdominal girth, jaundice, pruritus, confusion, pedal edema)
  9. Cardiac symptoms (e.g., pedal edema, shortness of breath, orthopnea, chest pain)
  10. Hypothyroid disease (fatigue, weight gain, constipation)
  11. History of ascites, prior treatment, LVP requirements and frequency
- Important physical exam findings:
  1. Protuberant abdomen (Fig. E1)
  2. Bulging flanks (can be present in obesity)
  3. Flank dullness to percussion (requires ~1500 ml of fluid)
  4. Fluid wave on abdominal exam
  5. Lower extremity edema
  6. Shifting dullness on abdominal exam
  7. Physical signs associated with liver cirrhosis: Spider angiomas, jaundice, loss of body hair, skeletal muscle wasting (sarcopenia), Dupuytren contracture, bruising, palmar erythema, gynecomastia, testicular atrophy, rectal varices, and caput medusae

ETIOLOGY

Pathophysiology of ascites (Fig. E2): Increased hepatic resistance to portal flow leads to portal hypertension. A portal pressure >12 mm Hg appears to be required for fluid retention. The splanchnic vessels respond by increased secretion of nitric oxide, causing splanchnic artery vasodilation. Vasodilation appears also to be mediated by the translocation of enteric bacteria and bacterial products. Early in the disease increased plasma volume and increased cardiac output compensate for this vasodilation. However, as the disease progresses the effective arterial blood volume decreases, causing sodium and fluid retention through activation of the renin-angiotensin system. Over time activation of the sympathetic system causes renal vascular perfusion to decrease and may lead to hepatorenal syndrome. The change in capillary pressure causes increased permeability and retention of fluid in the abdomen.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Chronic parenchymal liver disease, leading to portal hypertension
- Acute liver failure
- Noncirrhotic portal hypertension (e.g., portal vein clot)
- Peritoneal carcinomatosis
- Cardiac disease (e.g., heart failure, constrictive pericarditis)
- Hepatic venous outflow obstruction (e.g., Budd-Chiari syndrome, IVC webs)
- Protein losing enteropathy
- Peritoneal tuberculosis
- Nephrotic syndrome
- Pancreatitis

LABORATORY TESTS

- Initial evaluation should always include:
  1. Diagnostic paracentesis. Laboratory tests on this fluid should include a cell count and differential, cytology, albumin, total protein, culture, and Gram stain. A serum-ascites albumin gradient (SAAG) should be calculated in all patients. The SAAG is measured by subtracting the level of albumin in the ascitic fluid from a concurrent serum albumin measurement: SAAG = serum albumin – ascites albumin
     a. If the SAAG is greater than 1.1, the cause of ascites can be attributed to portal hypertension (from Cirrhosis, Budd-Chiari syndrome) or heart failure.
     b. If SAAG is less than 1.1, a non-portal hypertension etiology of ascites must be sought. Optional tests on paracentesis fluid include amylase, LDH, acid-fast bacilli, and glucose levels.
     c. Total ascitic fluid protein assess the risk of spontaneous bacterial peritonitis (SBP). Patients with protein concentration <1.5 g/dl have an increased risk of SBP.
  2. AST, ALT, total and direct bilirubin, albumin, alkaline phosphatase, GGTP
  3. CBC, coagulation studies
  4. Electrolytes, BUN, creatinine
- Causes of ascites in the normal or diseased peritoneum by SAAG are summarized in Table 1.
- Fig. 3 illustrates an algorithm for the approach to the differential diagnosis of ascites.

IMAGING STUDIES

- Abdominal ultrasound (Fig. 4) is the most sensitive measure for detecting ascitic fluid; a CT or MRI scan is a viable alternative. Doppler studies of portal and hepatic veins should be added to rule out vascular etiology.
- Endoscopy of the upper GI tract to evaluate for esophageal varices if ascites is secondary to portal hypertension.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Sodium-restricted diet (88 mmol, <2 g/day).
- Fluid restriction to 1 L/day in patients with severe hyponatremia (sodium <120 mEq/L).
- Counsel on avoiding NSAIDs and discontinuation of ACE inhibitors and ARBs.
- Consider discontinuing or not initiating propranolol in patients with refractory ascites.

ACUTE GENERAL Rx

- Patients with moderate-volume ascites causing only moderate discomfort may be treated on an outpatient basis with the following diuretic regimen:
  1. Spironolactone: Start at 50 to 100 mg/day and titrate up to 400 mg day every 3 to 4 days (monotherapy or combination therapy with furosemide).
  2. Furosemide: Start at 40 mg/day and titrate up to 160 mg/day maximum. Monitor renal function and sodium levels carefully for signs of prerenal azotemia (in patients without edema. Goal weight loss is 300 to 500 g/day; in patients with edema, goal weight loss is 800 to 1000 g/day). Furosemide alone is not recommended.

TABLE 1 Causes of Ascites in the Normal or Diseased Peritoneum by Serum-to-Ascites Albumin Gradient (SAAG)

Normal Peritoneum	
Portal Hypertension (SAAG >1.1 G/dl)	**Hypoalbuminemia (SAAG <1.1 g/dl)**
Hepatic congestion	Nephrotic syndrome
Congestive heart failure	Protein-losing enteropathy
Constrictive pericarditis	Severe malnutrition with anasarca
Tricuspid insufficiency	
Budd-Chiari syndrome	
Liver Disease	**Miscellaneous Conditions (SAAG <1.1 g/dl)**
Cirrhosis	Chylous ascites
Alcoholic hepatitis	Pancreatic ascites
Fulminant hepatic failure	Bile ascites
Massive hepatic metastases	Nephrogenic ascites
	Urine ascites
	Ovarian disease
Diseased Peritoneum (SAAG <1.1 g/dl)	
Infections	**Other Rare Conditions**
Bacterial peritonitis	Familial Mediterranean fever
Tuberculous peritonitis	Vasculitis
Fungal peritonitis	Granulomatous peritonitis
HIV-associated peritonitis	Eosinophilic peritonitis
Malignant Conditions	
Peritoneal carcinomatosis	
Primary mesothelioma	
Pseudomyxoma peritonei	
Hepatocellular carcinoma	

From Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.

- Patients with large-volume ascites causing marked discomfort or decrease in activities of daily living may also be treated as outpatients if there are no complications. There are two options for treatment in these patients:
  1. Large-volume paracentesis or
  2. Diuretic therapy until loss of fluid is noted (maximum spironolactone 400 mg daily and furosemide 160 mg daily).
     a. No difference in long-term mortality rate was found; however, paracentesis is faster, more effective, and associated with fewer adverse effects.
     b. Patients receiving large-volume paracentesis should receive albumin replacement therapy at the dose of 7 to 9 g/L of fluid removed if more than 5 L are taken out to prevent paracentesis-induced circulatory dysfunction (PICD). Patients with renal dysfunction or hyponatremia should receive albumin for lower volumes as well.
- Table 2 summarizes primary medical therapy and adjunctive medications used to increase the efficacy of primary therapy in the treatment of ascites.

CHRONIC Rx

- 5% to 10% of patients with large-volume ascites will be refractory to high-dose diuretic treatment. Treatment strategies include repeated large-volume paracentesis with infusion of albumin every 2 to 4 wk or placement of a transjugular intrahepatic portosystemic shunt (TIPS).
- TIPS evaluation should include echocardiogram, assessment for hepatic encephalopathy, and characterization of liver impairment.
- Discuss referral to transplant-capable center.
- Patients known to have ascites should receive a diagnostic tap if they develop any signs of SBP or on any admission to the hospital even in the absence of these signs.
- Primary prophylaxis for SBP is recommended in patients with ascitic fluid protein <1.5 g/dl along with impaired renal function (creatinine ≥1.2 mg/dl or 106 micromol/L), BUN ≥25 mg/dl or 8.9 mmol/L or Na ≤130 mEq/L or 130 mmol/L, or liver failure (Child-Pugh score ≥9 and bilirubin ≥3 mg/dl or 51 micromol/L).
- Secondary prophylaxis should be instituted in all patients who were diagnosed with SBP in the form of a daily fluoroquinolone, ciprofloxacin or norfloxacin, or double strength trimethoprim-sulfamethoxazole
- Patients with known ascites who develop gastrointestinal bleeding should receive intravenous ceftriaxone for 7 days to prevent bacterial infections.
- Clinical use of Vaptan agents is not currently recommended in cirrhotic patients.
- Oral midodrine 7.5 mg three times daily has been shown to increase urine volume, urine sodium, mean arterial pressure, and survival.
- Peritoneovenous shunts or surgical portosystemic shunts have poor evidence and are not recommended.
- The Alfapump system (not approved in North America) works by transporting small amounts of fluid from the peritoneal cavity to the bladder. Studies have shown improved symptoms and reduced LVP requirements.
- Liver transplantation remains definitive management for cirrhosis with refractory ascites.
- Table 3 summarizes the management of refractory ascites.
- A treatment approach to patients with malignant ascites is described in Fig. E5.

DISPOSITION

- Development of ascites signals a shift to decompensated cirrhosis and close follow-up is required.
- Monitor closely for worsening liver function and development of spontaneous bacterial peritonitis (SBP).

REFERRAL

Referral to hepatology at a transplant-capable center.

PEARLS & CONSIDERATIONS

COMMENTS

- Prevalence of SBP in patients with ascites ranges between 10% and 30%.
  1. Presence of at least 250 neutrophils per cubic millimeter of ascitic fluid is diagnostic.
  2. Gram-negative bacteria such as *E. coli* are the most common isolates.
  3. Third-generation cephalosporins are the treatment of choice.
  4. By 1 yr, 70% of patients have recurrence of SBP and may be prophylaxed with ciprofloxacin 750 mg PO once/wk.

PREVENTION

- Prevention of liver cirrhosis through avoidance of long-term use of alcohol, immunization against hepatitis A and B, and treatment of hepatitis C
- In cirrhotic patients, following a low-sodium diet (<2 g daily)

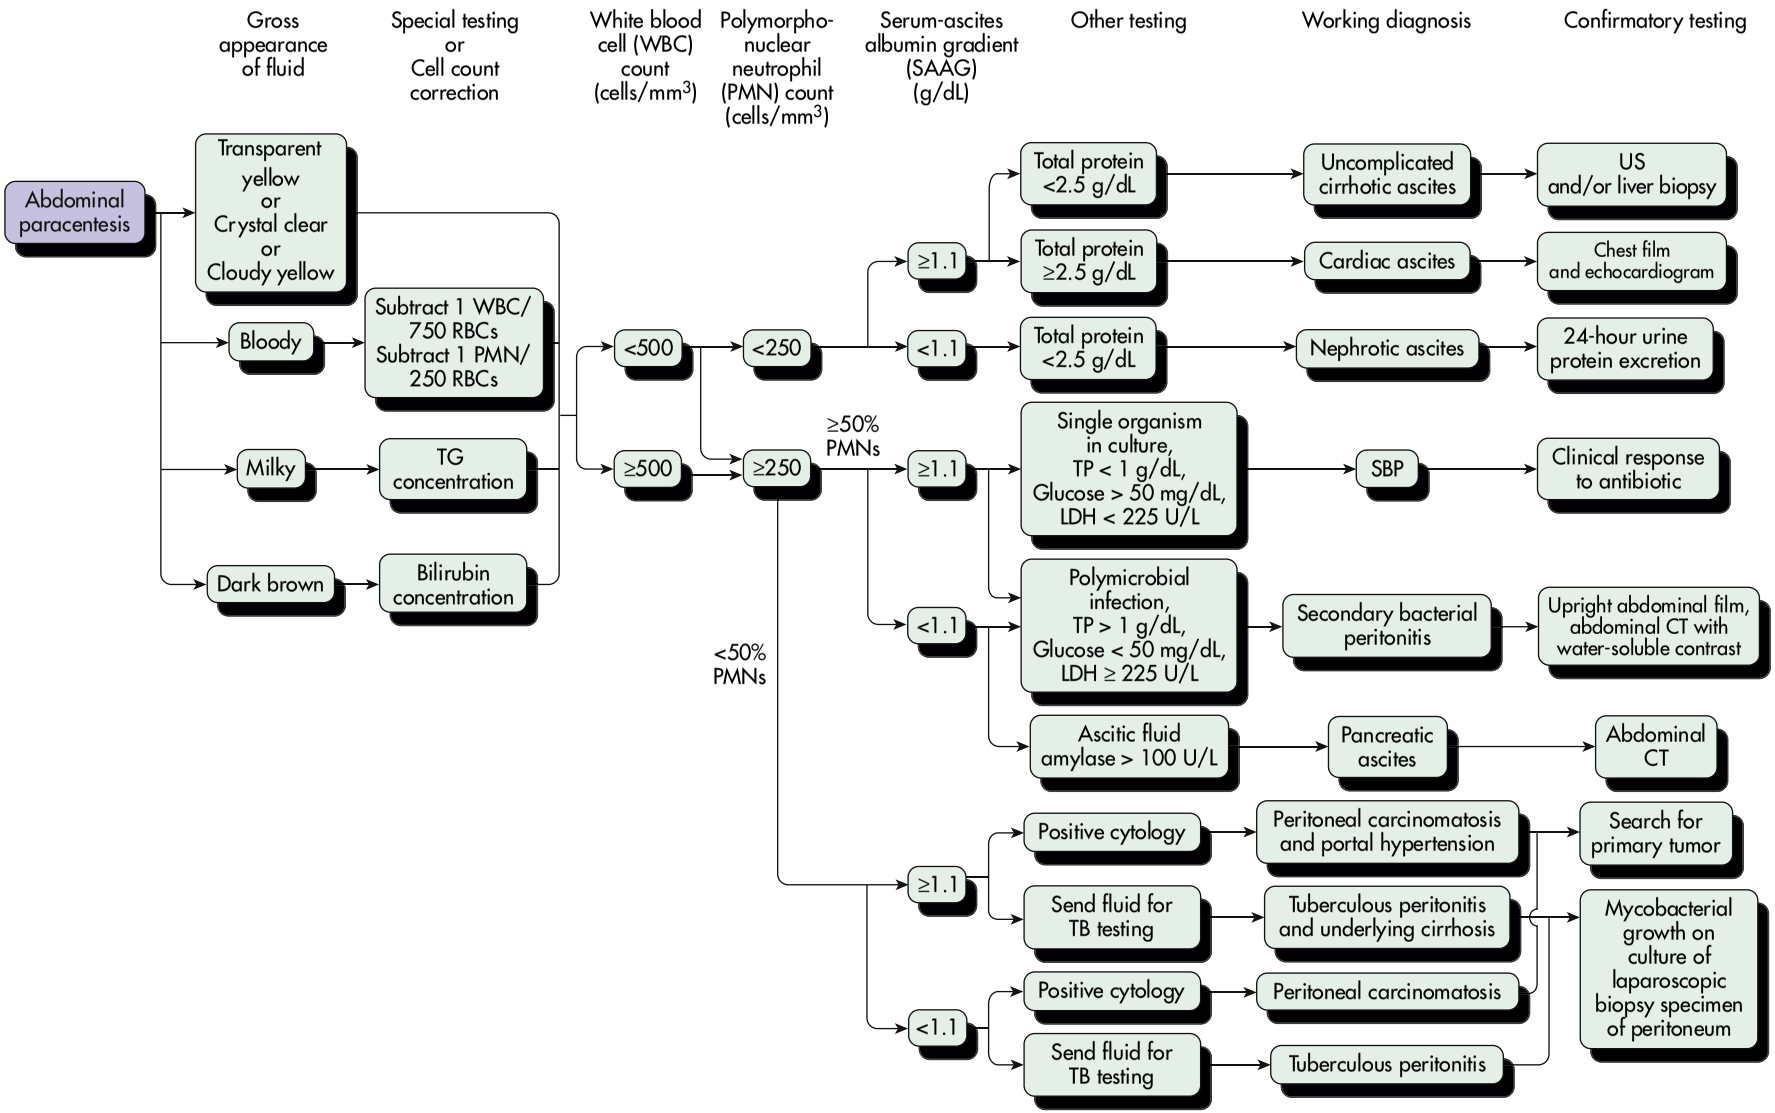

FIG. 3 Algorithm for the approach to the differential diagnosis of ascites. *LDH,* Lactic dehydrogenase; *PMN,* polymorphonuclear neutrophil; *RBC,* red blood cell; *TP,* total protein. (From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.)

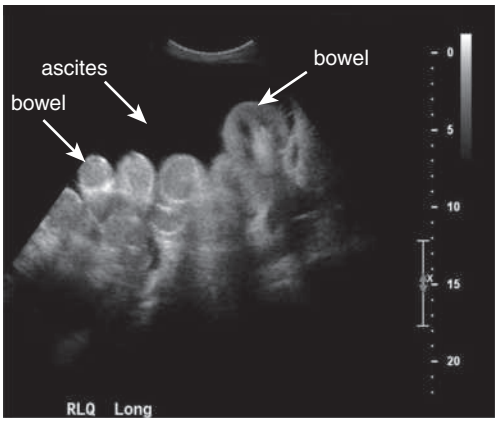

FIG. 4 Ascites, ultrasound. Ultrasound is useful for detection of ascites. Simple fluids such as ascites are excellent sound transmission media, reflecting almost no sound waves. As a consequence, they appear quite hypoechoic *(black)* on ultrasound. This view of the right lower quadrant shows loops of bowel surrounded by fluid. During the ultrasound, the bowel loops would be seen to undergo peristalsis and drift back and forth in the ascitic fluid with patient movement. Ultrasound cannot distinguish the composition of the fluid; ascites, liquid blood, liquid bile, urine, and infectious fluids have a similar appearance, with a few exceptions. Blood may coagulate and form septations within the fluid collection. Infectious fluids also frequently form loculated fluid collections that may be recognized on ultrasound, although the exact composition cannot be determined. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.)

TABLE 2 Primary Medical Therapy and Adjunctive Medications Used to Increase the Efficacy of Primary Therapy in the Treatment of Ascites

Class	Medication	Dosing	Relevant Action	Notes
Diuretics	Spironolactone	400 mg + daily*	Aldosterone receptor antagonist	Primary therapy
	Furosemide	160 mg + daily*	Inhibits Na-K-2Cl symporter	Primary therapy
Vasoconstrictors	Octreotide	300 mcg bid*	Splanchnic vasoconstriction, inhibits RAAS	Also used in combination with midodrine to treat hepatorenal syndrome; given for first 5 days following variceal bleeding to decrease recurrence
	Midodrine	7.5 mg tid*	Inhibits RAAS	Also used in combination with octreotide and albumin to treat hepatorenal syndrome
α2-Agonist	Clonidine	0.075 mg bid*	Inhibits sympathetic outflow, inhibits RAAS	Increases sensitivity to spironolactone
Colloid	Albumin	25 g*	Increased oncotic pressure	Also utilized with large-volume paracentesis and in the treatment of hepatorenal syndrome

RAAS, Renin-angiotensin-aldosterone system
*The above doses have been derived from various studies and may not be suitable for all patients. Titration is always recommended.

BASIC INFORMATION

DEFINITION

Aspergillosis refers to several forms of a broad range of illnesses caused by infection with *Aspergillus* species. Fig. 1 illustrates the spectrum of *Aspergillus* infection.

ICD-10CM CODES

B44.0	Invasive pulmonary aspergillosis
B44.1	Other pulmonary aspergillosis
B44.2	Tonsillar aspergillosis
B44.7	Disseminated aspergillosis
B44.81	Allergic bronchopulmonary aspergillosis
B44.89	Other forms of aspergillosis
B44.9	Aspergillosis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE & PREVALENCE:

- *Aspergillus* species are ubiquitous in the environment internationally and occur as a mold found in soil. *Aspergillus fumigatus* is the most common human pathogen.
- Cause a variety of illness from hypersensitivity pneumonitis to disseminated overwhelming infection in immunosuppressed patients.
- Frequently cultured from hospital wards from unfiltered outside air circulating through open windows as well as water sources.
- Reach the patient by airborne conidia (spores) that are small enough (2.5 to 3 μm) to reach the alveoli on inhalation.
- Can invade the nose, paranasal sinuses, external ear, or traumatized skin.

RISK FACTORS:

- The clinical syndrome depends on the underlying lung architecture, the host's immune response, and the degree of inoculum.
- Incidence of invasive aspergillosis is increasing with advances in the treatment of life-threatening diseases, such as aggressive chemotherapy or bone marrow and organ transplantation. It also can rarely occur in normal hosts, especially associated with influenza A. Liver and lung transplant recipients are at highest risk for pulmonary disease. Genetic deficiency of the soluble-pattern-recognition receptor known as long pentraxin 3 (PTX3) affects the antifungal capacity of neutrophils and may contribute to the risk of invasive aspergillosis in patients treated with hematopoietic stem-cell transplantation (HSCT).
- Patients with AIDS and a CD4 count <50/mm^3 have an increased susceptibility to invasive aspergillosis, but it is otherwise uncommon in patients with HIV.
- Pandemic influenza A (H1N1) infection may predispose immunocompromised patients to invasive aspergillosis.
- Patients with chronic granulomatous disease are at higher risk for infections with *Aspergillus* species.

ETIOLOGY

- *A. fumigatus* is the usual cause.
- *A. flavus* is the second most important species, particularly in invasive disease of immunosuppressed patients and in lesions beginning in the nose and paranasal sinuses. *A. niger* can also cause invasive human infection.

ALLERGIC ASPERGILLOSIS:

- Is a hypersensitivity pneumonitis.
- Presents as cough, dyspnea, fever, chills, and malaise typically 4 to 8 hr after exposure.
- Repeated attacks can lead to granulomatous disease and pulmonary fibrosis.

ALLERGIC BRONCHOPULMONARY ASPERGILLOSIS (ABPA):

- Symptoms occur most commonly in atopic individuals during the third and fourth decades of life.
- Hypersensitivity reaction to *Aspergillus* fungal antigens present in the bronchial tree.
- Results from an initial type I (immediate hypersensitivity) and type III reactions (immune complexes).
- Underdiagnosed pulmonary disorder in patients with asthma and cystic fibrosis (reported prevalence in asthmatic patients varies from 6% to 28% and in cystic fibrosis 6% to 25%).

ASPERGILLOMAS ("FUNGUS BALLS"):

- In the absence of invasion or significant immune response, *Aspergillus* can colonize a preexisting cavity, causing pulmonary aspergilloma.
- Forms masses of tangled hyphal elements, fibrin, and mucus.
- Patients typically have a history of chronic lung disease, tuberculosis, sarcoidosis, or emphysema.
- Manifests commonly as hemoptysis.
- Many are asymptomatic.

INVASIVE ASPERGILLOSIS:

- Patients with prolonged and profound granulocytopenia or impaired phagocytic function are predisposed to rapidly progressive *Aspergillus* pneumonia.
- Typically a necrotizing bronchopneumonia, ranging from small areas of infiltrate to intensive bilateral hemorrhagic infarction.
- Most common presentation: Unremitting fever and a new pulmonary infiltrate despite broad-spectrum antibiotic therapy in an immunosuppressed patient.
- Dyspnea and nonproductive cough are common; sudden pleuritic pain and tachycardia, sometimes with a pleural rub, may mimic pulmonary embolism; hemoptysis is uncommon.
- Chest radiograph (CXR) may reveal patchy bronchopneumonic, nodular densities, consolidation, or cavitation. High-resolution CT scan is more sensitive and specific than CXR in neutropenic patients.
- Immunocompromised patients: Invasive pulmonary *Aspergillus* (IPA) generally is acute and evolves over days to weeks; less commonly, patients with normal or only mild abnormalities of the immune system may develop a more chronic, slowly progressive form of IPA.

EXTRAPULMONARY DISSEMINATION:

- Cerebral infarction from hematogenous dissemination may occur in immunosuppressed individuals.
- Abscess formation from direct extension or invasive disease in the sinuses.
- Esophageal or gastrointestinal ulcerations may occur in the immunosuppressed host.
- Fatal perforation of the viscus or bowel infarction may occur.
- Necrotizing skin ulcers (Fig. E2).
- Osteomyelitis.
- Endocarditis in patients who have recently undergone open heart surgery.
- Infection of an implantable cardioverter-defibrillator has been reported.

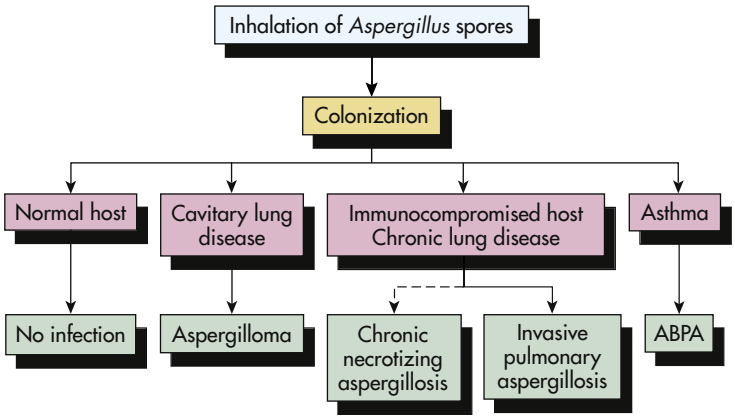

FIG. 1 The spectrum of *Aspergillus* infection. *ABPA,* Allergic bronchopulmonary aspergillosis. (From Sellke FW, del Nido PJ, Swanson SJ: *Sabiston & Spencer surgery of the chest,* ed 9, Philadelphia, 2016, Elsevier.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Tuberculosis
- Cystic fibrosis
- Carcinoma of the lung
- Eosinophilic pneumonia
- Bronchiectasis
- Sarcoidosis
- Lung abscess

WORKUP

Physical examination and laboratory data

LABORATORY TESTS

ABPA:

- Peripheral blood eosinophilia and an elevated total serum immunoglobulin E (IgE) level.
- Skin test with *Aspergillus* antigenic extract is usually positive but nonspecific.
- *Aspergillus* serum precipitating antibody is present in 70% to 100% of cases.
- Sputum cultures may be positive for *Aspergillus* spp. but are nonspecific.

ASPERGILLOMAS:

- Sputum culture
- Serum precipitating antibody

INVASIVE ASPERGILLOSIS:

- Definitive diagnosis requires the demonstration of tissue invasion (i.e., septate, acute angle branching hyphae) or a positive culture from the tissue obtained by an invasive procedure such as transbronchial biopsy.
- Sputum and nasal cultures: In high-risk patients a positive culture is strongly suggestive of invasive aspergillosis.
- Serology: The *Platelia Aspergillus* ELISA assay detects a circulating fungal antigen, galactomannan. The **Galactomannan antigen immunoassay** is often used for diagnosis. Galactomannan is a polysaccharide contained in the cell wall of *Aspergillus.* Its presence in serum or other body fluids is indicative of invasive infection, and it is recommended as an accurate marker for diagnosis in certain patient subpopulations (hematologic malignancy and hematopoietic stem cell transplantation). The sensitivity of the Galactomannan antigen immunoassay can be impaired by antifungal therapy. The β-D glucan assay can also be used to detect early infection, but is not specific for *Aspergillus* species.[1]
- Blood cultures: Usually negative.
- Lung biopsy is necessary for definitive diagnosis.
- Biopsy and culture of extrapulmonary lesions.
- Polymerase chain reaction assays may be employed, but their results should be interpreted in conjunction with other diagnostic tests and the clinical context.

IMAGING STUDIES

ABPA:

- CXRs show a variety of abnormalities, from small, patchy, fleeting infiltrates (commonly in the upper lobes) to lobar consolidation or cavitation.
- A majority of patients eventually develop central bronchiectasis.

ASPERGILLOMAS: CXR or CT scans usually show the characteristic intracavity mass (Figs. E3 and E4) partially surrounded by a crescent of air ("halo sign").

INVASIVE ASPERGILLOSIS: CXR and CT scanning may also reveal cavity formation and the halo sign. Air bronchograms typically disappear as they are filled with hemorrhagic fluid.

Rx TREATMENT

ACUTE GENERAL Rx

ABPA:

- Prednisone (0.5 to 1 mg/kg PO) until the CXR has cleared, followed by alternate-day therapy at 0.5 mg/kg PO (3 to 6 mo) plus itraconazole oral solution 2.5 mg/kg PO bid or 200 mg capsules bid for 16 weeks.
- If a patient is corticosteroid dependent, prophylaxis for the prevention of *Pneumocystis jiroveci* infection and maintenance of bone mineralization should be considered.
- Bronchodilators and physiotherapy.
- Serial CXR and serum IgE is useful in guiding treatment.

ASPERGILLOMAS:

- Controversial and problematic; the optimal treatment strategy is unknown.
- Up to 10% of aspergillomas may resolve clinically without overt pharmacologic or surgical intervention.
- Observation for asymptomatic patients.
- Surgical resection/arterial embolization for those patients with severe hemoptysis or life-threatening hemorrhage.
- For those patients at risk for marked hemoptysis with inadequate pulmonary reserve, consider itraconazole 200 to 400 mg/day PO. Voriconazole and posaconazole are also effective.

INVASIVE ASPERGILLOSIS:

- Voriconazole 6 mg/kg IV/PO bid on day 1 followed by 4 mg/kg IV/PO bid. Voriconazole serum concentrations need to be monitored to achieve a target range of 1.0 to 5.5 mg/L (trough on day 4).
- Isavuconazonium sulfate (prodrug of Isavuconazole) 372 mg IV/PO tid for six doses and then 372 mg IV/PO daily.

Alternative treatment:

- Amphotericin B lipid complex (ABLC) 5 mg/kg IV daily.
- Liposomal amphotericin B (L-AMB) 3 to 5 mg/kg IV daily.
- Posaconazole delayed-release tabs 300 mg PO for two doses, then 300 mg PO daily or posaconazole suspension 200 mgs qid, then 400 mg po bid after stabilization of disease or posaconazole 300 mg IV over 90 minutes bid for one day, then 300 mg IV daily.
- Because azoles and echinocandins target different cellular sites, combination therapy may have additive activity against *Aspergillus* species.

REFERRAL

To an infectious diseases specialist

PEARLS & CONSIDERATIONS

- Unlike fluconazole, the potential for drug-drug interactions with voriconazole is high. Azoles may interact with drugs used for chemotherapy by increasing toxicity and/or by reducing efficacy.
- Azole resistance has appeared in *Aspergillus fumigatus*; the main resistance mechanism is a point mutation of CYP51A, the gene coding for 14 alpha-sterol demethylase, the target enzyme of antifungal drugs. Global prevalence of azole resistance in *Aspergillus* is estimated to be approximately 3% to 6%.
- Agitation of hospital buildings by renovations or repairs may increase the incidence of *Aspergillus* infections in immunosuppressed individuals.
- Echinocandins should never be used as primary treatment of aspergillosis.
- *Aspergillus and Nocardia* species may co-infect.
- Use of antifungal agents in combination is discussed in Box 1.

Aspergillosis (Patient Information)

AUTHOR: **Sajeev Handa, MD, SFHM**

[1] False-negative results occur in patients who are receiving antifungal agents other than fluconazole. The sensitivity of the galactomannan assay for invasive pulmonary aspergillosis is higher in brochoalveolar lavage fluid than in serum. In patients with risk factors and radiologic findings suggestive of invasive aspergillosis, a positive galactomannan confirms the diagnosis of probable invasive pulmonary aspergillosis.

BOX 1 Use of Antifungal Agents in Combination

The development of new antifungal drugs gives the clinician more options for prophylaxis and therapy than in previous years. There is an overall level of simplicity to the drug choices once their mechanisms of action are understood. The polyenes, including amphotericin products and the topical agent nystatin, attach onto ergosterol in the fungal cell membrane and are considered fungicidal, because cytoplasm leaks out, and individual cells die. The azoles, including fluconazole, itraconazole, voriconazole, and posaconazole, prevent the formation of new ergosterol. Azoles are considered fungistatic, because removal of the drug permits cell regrowth. Theoretically, use of an azole together with a polyene may have an overall static effect for an established infection as the ergosterol target for the fungicidal polyene is depleted. However, this combination may have advantages in terms of enhanced spectrum of activity. The echinocandins, including caspofungin, micafungin, and anidulafungin, prevent interaction of the catalytic and regulatory subunits of the β-glucan synthesis enzyme, so less β-glucan is formed for the cell wall. The scaffolding for the fungal cell wall is not maintained, and a dividing cell may burst open when trying to extend the new cell wall over daughter cells. The echinocandins are considered fungicidal for yeasts but fungistatic for molds, because drug activity is concentrated at only the tips of the extending hyphae with little effect on less metabolically active subapical compartments of the fungus. Combination therapy may have the most effect when a cell wall agent (an echinocandin) is used together with a cell membrane agent (a polyene or an azole). There is no role for three-drug therapy (an echinocandin, a polyene, and an azole). Aside from cases of cryptococcal meningitis, in which the importance of combination therapy is well established, the benefits of frontline use of combination antifungal for molds remain controversial, although active investigation continues in clinical trials. The value of combination regimens as salvage therapy for refractory mold infections remains uncertain.

BASIC INFORMATION

DEFINITION

Aspiration pneumonia is a vague term that refers to pulmonary abnormalities following abnormal entry of endogenous or exogenous substances in the lower airways. It can be considered part of the continuum that also includes community- and hospital-acquired pneumonias. It is generally classified as:

- Aspiration (chemical pneumonitis)
- Primary bacterial aspiration pneumonia
- Secondary bacterial infection of chemical pneumonitis

SYNONYM

Pneumonia, aspiration

ICD-10CM CODE

J69.0 Pneumonitis due to inhalation of food and vomit

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- 20% to 35% of all pneumonias
- 5% to 15% of all community-acquired pneumonias

PEAK INCIDENCE: Elderly patients in hospitals or nursing homes

PREVALENCE (IN U.S.): Unknown (unreliable data)

PREDOMINANT SEX: Males and females affected equally

PREDOMINANT AGE: Elderly

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Shortness of breath, tachypnea, cough, sputum, fever after vomiting, or difficulty swallowing
- Rales, rhonchi, often diffusely throughout lung

ETIOLOGY

Complex interaction of etiologies, ranging from chemical (often acid) pneumonitis after aspiration of sterile gastric contents (generally not requiring antibiotic treatment) to bacterial aspiration. Risk factors for aspiration pneumonia include vomiting, decreased consciousness, poor dentition, ineffective cough reflex, and gastroesophageal reflux disease. Table 1 summarizes risk factors for aspiration pneumonia.

COMMUNITY-ACQUIRED ASPIRATION PNEUMONIA:

- Generally results from predominantly anaerobic mouth bacteria (anaerobic and microaerophilic streptococci, fusobacteria, gram-positive anaerobic non–spore-forming rods), *Bacteroides* species (*melaninogenicus*, *intermedius*, *oralis*, *ureolyticus*), *Haemophilus influenzae,* and *Streptococcus pneumoniae*
- Rarely caused by *Bacteroides fragilis* (of uncertain validity in published studies) or *Eikenella corrodens*
- High-risk groups: The elderly; alcoholics; IV drug users; patients who are obtunded; stroke victims; and those with esophageal disorders, seizures, poor dentition, or recent dental manipulations

HOSPITAL-ACQUIRED ASPIRATION PNEUMONIA:

- Often occurs among elderly patients and others with diminished gag reflex; those with nasogastric tubes, intestinal obstruction, or ventilator support; and especially those exposed to contaminated nebulizers or unsterile suctioning.
- High-risk groups: Seriously ill hospitalized patients (especially patients with coma, acidosis, alcoholism, uremia, diabetes mellitus, nasogastric intubation, or recent antimicrobial therapy, who are frequently colonized with aerobic gram-negative rods); patients undergoing anesthesia; those with strokes, dementia, or swallowing disorders; the elderly; and those receiving antacids or H_2 blockers, or proton pump inhibitors (but not sucralfate).
- Hypoxic patients receiving concentrated O_2 have diminished ciliary activity, encouraging aspiration.
- Causative organisms:
  1. Anaerobes listed above, although in many studies gram-negative aerobes (60%) and gram-positive aerobes (20%) predominate.
  2. *E. coli, P. aeruginosa, S. aureus* including MRSA, *Klebsiella, Enterobacter, Serratia, Proteus* spp., *H. influenzae, S. pneumoniae, Legionella,* and *Acinetobacter* spp. (sporadic pneumonias) in two thirds of cases.
  3. Fungi, including *Candida albicans,* in <1%.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other necrotizing or cavitary pneumonias (especially tuberculosis, gram-negative pneumonias)
- See "Tuberculosis, Pulmonary"

WORKUP

- Chest x-ray
- Complete blood count (CBC), blood cultures
- Sputum gram stain and culture
- Consideration of tracheal aspirate

LABORATORY TESTS

- CBC: Leukocytosis often present.
- Sputum gram stain:
  1. Often useful when carefully prepared immediately after obtaining suctioned or expectorated specimen, examined by experienced observer.
  2. Only specimens with multiple white blood cells and rare or absent epithelial cells should be examined.
  3. Unlike nonaspiration pneumonias (e.g., pneumococcal), multiple organisms may be present.
  4. Long, slender rods suggest anaerobes.
  5. Sputum from pneumonia caused by acid aspiration may be devoid of organisms.
  6. Cultures should be interpreted in light of morphology of visualized organisms.

IMAGING STUDIES

- Chest x-ray often reveals bilateral, diffuse, patchy infiltrates and posterior segment upper lobes (Fig. 1). Chemical pneumonitis typically affects the most dependent regions of the lungs. The chest x-ray may be negative early in the course of aspiration pneumonia.
- Aspiration pneumonia of several days' or longer duration may reveal necrosis (especially community-acquired anaerobic pneumonias) and even cavitation with air-fluid levels, indicating lung abscess.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Airway management to prevent repeated aspiration
- Ventilatory support if necessary
- Rehabilitative management: Physical, pulmonary, and dysphagia therapy combined with appropriate nutrition can reduce length of stay and mortality

ACUTE GENERAL Rx

- **Chemical pneumonitis:** Acute aspiration of acidic gastric contents without bacteria may not require antibiotic therapy; initial treatment involves airway maintenance and management of bronchospasm and airway edema. Routine adjunctive treatment with glucocorticoids is not recommended. Consultation with an infectious disease or pulmonary expert is recommended.
- **Aspiration pneumonia:** Antibiotic selection depends on the site of acquisition (long-term care facility, hospital, community), which modifies risk factors for infection with multidrug-resistant pathogens.

TABLE 1 Risk Factors for Dysphagia and Aspiration Pneumonia

Cerebrovascular disease
Ischemic stroke
Hemorrhagic stroke
Subarachnoid hemorrhage
Degenerative neurologic disease
Alzheimer disease
Multi-infarct dementia
Parkinson disease
Amyotrophic lateral sclerosis (motor neuron disease)
Multiple sclerosis
Head and neck cancer
Oropharyngeal malignancy
Oral cavity malignancy
Esophageal malignancy
Other
Scleroderma
Diabetic gastroparesis
Reflux esophagitis
Presbyesophagus
Achalasia

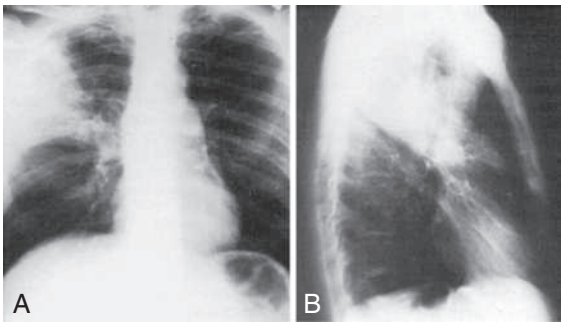

FIG. 1 Anaerobic necrotizing pneumonia following aspiration of oropharyngeal secretions. Multiple, small (<2 cm) radiolucencies are seen throughout the posterior segment of the right upper lobe on the postero-anterior **(A)** and lateral **(B)** projections. (Courtesy Michael Gotway, MD. From Mason RJ et al: *Murray & Nadel's textbook of respiratory medicine*, ed 5, Philadelphia, 2010, Saunders.)

- Community-acquired aspiration pneumonia or hospital-acquired cases with low risk of multidrug-resistant pathogens: Ampicillin-sulbactam 1.5 to 3 g every 6 hours IV, or amoxicillin-clavulanate PO 875 mg twice daily, or a fluoroquinolone (levofloxacin 750 mg IV or PO) is effective. Clindamycin (450 mg oral qid or 600 mg IV every 8 hours) can be added to the other agent when the risk of predominantly anaerobic infection is high.
- Nursing home aspirations or hospital-acquired aspiration pneumonias with concerns for resistance: Broad-spectrum treatment with piperacillin-tazobactam 3.375 g q6h or cefepime 2 g q8h ± vancomycin (15 mg/kg q12h IV) or linezolid (600 mg q12h PO or IV) if MRSA is suspected or known (e.g., documented nasal or respiratory colonization with MRSA).
  1. Knowledge of resident flora in the micro-environment of the aspiration within the hospital is crucial to intelligent antibiotic selection; consult infection control nurses or hospital epidemiologist.
  2. Confirmed *Pseudomonas* pneumonia should be treated with antipseudomonal beta-lactam agent (piperacillin/tazobactam, cefepime, meropenem) plus an aminoglycoside until antimicrobial sensitivities confirm that less toxic agents may replace the aminoglycoside.

DISPOSITION

Repeat chest x-ray in 6 to 8 wk in most patients.

REFERRAL

For consultation with infectious disease and/or pulmonary experts for patients with respiratory distress, hypoxia, ventilatory support, pneumonia in more than one lobe, or necrosis or cavitation on x-ray examination or for those not responding to antibiotic therapy within 2 to 3 days.

BASIC INFORMATION

DEFINITION

The National Asthma Education and Prevention Program (NAEPP) guidelines define asthma as "a chronic inflammatory disease of the airways in which many cells and cellular elements play a role: in particular mast cells, neutrophils, eosinophils, T lymphocytes, macrophages, and epithelial cells. In susceptible individuals, this inflammation causes recurrent episodes of coughing (particularly at night or early in the morning), wheezing, breathlessness, and chest tightness. The episodes are usually associated with widespread but variable airflow obstruction that is reversible either spontaneously or as a result of treatment." **Status asthmaticus,** or acute severe asthma, is a refractory state that does not respond to standard therapy such as inhaled beta-agonists or subcutaneous epinephrine. It may persist for several hours.

SYNONYMS

Bronchospasm
Reactive airway disease
Asthmatic bronchitis

ICD-10CM CODES

J45.20	Mild intermittent asthma, uncomplicated
J45.21	Mild intermittent asthma with (acute) exacerbation
J45.22	Mild intermittent asthma with status asthmaticus
J45.30	Mild persistent asthma, uncomplicated
J45.31	Mild persistent asthma with (acute) exacerbation
J45.32	Mild persistent asthma with status asthmaticus
J45.40	Moderate persistent asthma, uncomplicated

J45.51	Severe persistent asthma with (acute) exacerbation
J45.52	Severe persistent asthma with status asthmaticus
J45.901	Unspecified asthma with (acute) exacerbation
J45.902	Unspecified asthma with status asthmaticus
J45.909	Unspecified asthma, uncomplicated
J45.991	Cough variant asthma
J45.998	Other asthma

EPIDEMIOLOGY & DEMOGRAPHICS

- Asthma has been diagnosed in 7.5% of the population in the U.S., and its prevalence is steadily rising among patients older than 65 yr, African Americans, women, and persons below the poverty level.
- It accounts for around 440,000 hospitalizations and 1.8 million emergency department visits yearly in the U.S.
- It is more common in children, but the gap is closing because of a rapid increase in adult-onset asthma (9.5% of children vs. 8.2% of adults).
- 50% to 80% of children with asthma develop symptoms before 5 yr of age. Early childhood risk factors for asthma are described in Table 1.
- The overall asthma mortality rate in the U.S. has slightly improved to 11 per 1 million persons.
- It is estimated that 300 million people have asthma. An increase in prevalence to 400 million is anticipated by 2025.
- Box 1 summarizes risk factors for severe and fatal asthma in adults.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Physical examination varies with the stage and severity of asthma and may reveal normal lung examination results in many patients. However, some degree of wheezing and prolonged expiratory phases of respiration are seen with persistent or acute disease. Box 2 summarizes signs and symptoms of severe asthma. Physical examination during status asthmaticus may reveal:

- Tachycardia and tachypnea
- Use of accessory respiratory muscles
- Pulsus paradoxus (inspiratory decline in systolic blood pressure >10 mm Hg)
- Absence of wheezing (silent chest) or decreased wheezing can indicate worsening obstruction
- Mental status changes: Generally secondary to hypoxia and hypercapnia and constitute an indication for urgent intubation
- Paradoxic abdominal and diaphragmatic movement on inspiration (detected by palpation over the upper part of the abdomen in a semirecumbent position) indicates diaphragmatic fatigue, another sign of impending respiratory crisis

TABLE 1 Early Childhood Risk Factors for Persistent Asthma

Parental asthma
Allergy:
Atopic dermatitis (eczema)
Allergic rhinitis
Food allergy
Inhalant allergen sensitization
Food allergen sensitization
Severe lower respiratory tract infection:
Pneumonia
Bronchiolitis requiring hospitalization
Wheezing apart from colds
Male gender
Low birthweight
Environmental tobacco smoke exposure
Possible use of acetaminophen (paracetamol)
Exposure to chlorinated swimming pools
Reduced lung function at birth

From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, WB Saunders.

BOX 1 Risk Factors for Severe and Fatal Asthma in Adults

- History of prior nonfatal asthma attack
- Prior intubation
- Female gender
- Age >65 yr
- African American ethnicity
- Obesity
- Tobacco use
- Inhalational drug abuse
- Poorly controlled disease
- Poor recognition of dyspnea and other symptoms
- Steroid dependence
- H1N1 viral infection
- Misuse or lack of proper use of maintenance medications
- Psychiatric illness
- Lack of access to medical care
- Lack of ability to limit triggers (i.e., persistent exposure to pollutants, dust)
- Comorbid heart disease, obesity, and/or diabetes
- Bronchoalveolar lavage predominance of neutrophils, interleukin 8, and matrix metalloproteinase

From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

BOX 2 Signs and Symptoms of Severe Asthma

- "Tripoding"—sitting upright and leaning forward
- Diaphoresis
- Use of accessory muscles
- Asynchronous accessory muscle use
- Air trapping and hyperinflation manifesting as decreased inspiratory stroke volume and pulsus paradoxus
- Peak flow <200 L/min and/or <30% predicted*
- FEV_1 <1 L/min and/or <20% predicted*
- Evidence of barotrauma:
  - Unilateral diminution in breath sounds
  - Tracheal deviation
  - Thoracic crepitus
- Signs of impending respiratory arrest:
  - Altered mentation
  - Cyanosis
  - Hypoxia
  - Hypercarbia
  - Hemodynamic instability
  - Silent chest

*These values are estimations because both peak expiratory flow rate and forced expiratory volume in 1 second (FEV_1) vary with age, gender, and height.
From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

- The following abnormalities in vital signs are indicative of severe asthma:
  1. Pulsus paradoxus >18 mm Hg
  2. Respiratory rate >30 breaths/min
  3. Tachycardia with heart rate >120 beats/min

ETIOLOGY

- The pathophysiology of asthma involves a complex interaction among various environmental and genetic factors. Genetic and phenotypic associations in asthma are described in Box 3.
- Allergic (extrinsic) asthma is triggered by various aeroallergens or nonspecific (e.g., dust, cigarette smoke, fumes, cold air, exercise) exposures in patients who are prone to develop IgE antibodies in response to various exposures. The pathogenesis of antigen-induced asthma is illustrated in Fig. 1.
- A recent study of a prebirth cohort observed that maternal intake of foods commonly considered allergenic (peanut and milk) was associated with a decrease in allergy and asthma in the offspring. No dietary changes during pregnancy are therefore recommended for prevention of allergies or asthma.
- A recent trial revealed that supplementation with n-3 long-chain polyunsaturated fatty acids (LCPUFAs, fish oil-derived fatty acids) in the third trimester of pregnancy reduced the absolute risk of persistent wheeze or asthma and infections of the lower respiratory tract in offspring by approximately 7 percentage points, or one third.[1]
- Nonallergic (intrinsic) asthma commonly manifests as adult-onset asthma in response to respiratory tract infection or psychological stress.
- Occupation exposure to certain organic or nonorganic agents can trigger asthma.
- Evidence suggests that dampness and mold contribute to the risk of developing asthma and that remediation of these in homes reduces asthma symptoms and medication use in adults.
- Exercise-induced asthma is seen most frequently in adolescents and manifests with bronchospasm after beginning of exercise and improves with discontinuation of exercise.
- Drug-induced asthma is associated with use of NSAIDs, β-blockers, sulfites, and certain foods and beverages.
- There is a strong association of the *ADAM 33* gene with asthma and bronchial hyperresponsiveness. Experimental, genetic, and clinical studies support an important role for Th2 immune pathways in the pathogenesis of severe asthma. Th2 cells are stimulated by dendritic cells to produce IL-5, IL-13, and IL-4, the latter driving IgE synthesis. This group is characterized by eosinophilia, and IL-5 is felt to be the most specific cytokine in eosinophil regulatory pathways.

BOX 3 Genetic and Phenotypic Associations in Asthma

- ***ADAM33:*** gene bronchoconstriction
- ***ORMDL3/GSDMB*** locus, chromosome 17q21: childhood onset
- CpG portion of ***ACSL3:*** associated with maternal exposure to automobile pollution
- ***IL33*** on chromosome 9
- ***IL2RB*** on chromosome 22

[1]Bisgaard H et al: Fish oil-derived fatty acids in pregnancy and wheeze and asthma in offspring, *N Engl J Med* 375:2530-2539, 2016.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Postinfectious bronchitis
- Rhinitis with postnasal drip
- COPD
- GERD
- Pneumonia and other upper respiratory infections
- Foreign body aspiration (most frequent in younger patients)
- Anxiety disorder
- Diffuse interstitial lung disease
- Hypersensitivity pneumonitis
- CHF
- Pulmonary embolism (in adult and elderly patients)

WORKUP

- Diagnosis of asthma requires documentation of airway obstruction and some degree of reversibility of the obstruction, if and when patient can participate.
- For symptomatic adults and children age >5 yr who can perform spirometry, pre- and postbronchodilator spirometry is the recommended test of choice.
- Airflow reversibility is defined as increase in forced expiratory volume in 1 sec (FEV_1 by at least 12% increase and 200 ml) after inhaling a short bronchodilator.
- The degree of reversibility measured by spirometry correlates with airway inflammation, and patients with a high degree of reversibility have a greater risk of irreversible airflow obstruction in subsequent years.

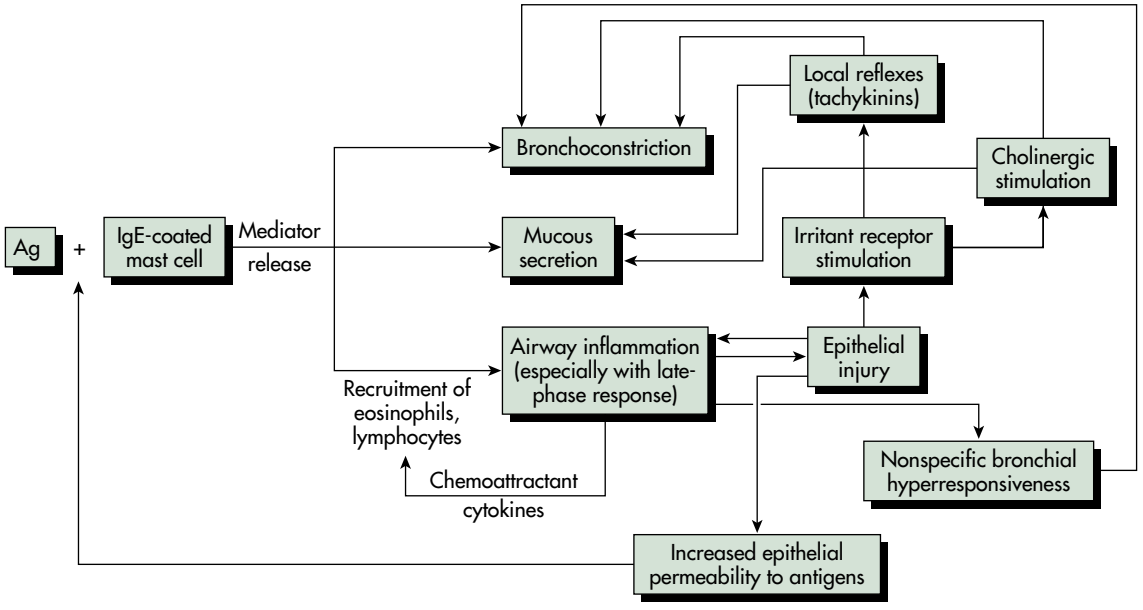

FIG. 1 Schematic diagram of events in pathogenesis of antigen-induced asthma. A hypothetical series of complex interactions is shown, focusing on bronchoconstriction, mucus secretion, and airway inflammation. *Ag,* Antigen; *IgE,* immunoglobulin E. (From Weinberger SE: *Principles of pulmonary medicine,* ed 7, Philadelphia, 2019, Elsevier.)

- For children age <5 yr, spirometry is generally not feasible. Young children with asthma symptoms should be treated as having suspected asthma after alternative diagnoses are ruled out.
- Negative spirometry results do not rule out asthma. Patients with high clinical suspicion should undergo bronchial challenge test using methacholine or other specific agents.
- The clinician should evaluate for environmental causes (e.g., house dust mites, indoor pets) and exposure to other allergens such as tobacco smoke. The degree of reversibility measured by spirometry correlates with airway inflammation, and patients with a high degree of reversibility have a greater risk of irreversible airflow obstruction in subsequent years.
- In the absence of spirometry testing, variability of peak flow measurements by a handheld device can be used to diagnose asthma.
- Fig. E2 describes an algorithm for diagnosing asthma.

After diagnosis, the severity of asthma should be classified during the initial assessment before initiating therapy. Patients are divided into four groups based on the severity of their asthma symptoms and number of exacerbations (see Table 2).

- Once therapy is initiated, the emphasis for clinical management should gear toward achievement of asthma control. The level of asthma control should be used to guide decisions either to maintain or adjust therapy.
- Schedule visits at 2- to 6-wk intervals for patients who are just starting therapy or who require a step up in therapy to achieve or regain asthma control. Schedule visits at 6- to 12-mo intervals, after asthma control is achieved, to monitor whether asthma control is maintained. The interval will depend on factors such as the duration of asthma control or the level of treatment required. Consider scheduling visits at 3-mo intervals if step-down therapy is anticipated.

LABORATORY TESTS

Laboratory tests are usually not necessary and the results can be normal if obtained during a stable period.

- Arterial blood gases (ABGs) can be used during acute bronchospasm in staging the severity of an asthmatic attack:
  1. Mild: Decreased Pa_{O_2} and Pa_{CO_2}, increased pH
  2. Moderate: Decreased Pa_{O_2}, normal Pa_{CO_2}, normal pH
  3. Severe: Marked decreased Pa_{O_2}, increased Pa_{CO_2}, and decreased pH
- Complete blood count: Leukocytosis with left shift may indicate the existence of bacterial infection. Elevated eosinophils point toward allergic component of asthma.
- Spirometry is recommended at the initial assessment and at least every 1 to 2 yr after treatment is initiated and when the symptoms and peak expiratory flow have stabilized. Spirometry as a monitoring measure may be performed more frequently, if indicated, based on severity of symptoms and the disease's lack of response to treatment.
- Peak expiratory flow rate (PEFR) can be used to assess severity of an acute exacerbation episode. Value should be compared with individual's personal best number (see asthma action plan).
- Serum IgE levels help guide treatment for patients with severe persistent asthma, and they also help monitor response to treatment in the same group.
- Specific allergy testing may be helpful in a subgroup of patients.

IMAGING STUDIES

- Chest x-ray: Usually normal, may show evidence of thoracic hyperinflation (e.g., flattening of the diaphragm, increased volume over the retrosternal air space).

TABLE 2 Classifying Asthma Severity and Initiating Treatment in Youths ≥12 Yr and Adults (Assessing severity and initiating treatment for patients who are not currently taking long-term control medications)

Components of Severity		CLASSIFICATION OF ASTHMA SEVERITY (≥12 YR)			
			PERSISTENT		
		Intermittent	Mild	Moderate	Severe
Impairment	Symptoms	≤2 days/wk	>2 days/wk but not daily	Daily	Throughout the day
Normal FEV_1/FVC: yr85% yr80% yr75% yr70%	Nighttime awakenings	≤2x/mo	3-4x/mo	>1x/wk but not nightly	Often 7x/wk
	Short-acting $beta_2$-agonist use for symptom control (not prevention of EIB)	≤2 days/wk	>2 days/wk but not daily, and not more than 1x on any day	Daily	Several times per day
	Interference with normal activity	None	Minor limitation	Some limitation	Extremely limited
	Lung function	Normal FEV_1 between exacerbations			
		FEV_1 >80% predicted	FEV_1 >80% predicted	FEV_1 >60% but <80% predicted	FEV_1 <60% predicted
		FEV_1/FVC normal	FEV_1/FVC normal	FEV_1/FVC reduced 5%	FEV_1/FVC reduced >5%
Risk	Exacerbations requiring oral systemic corticosteroids	0-1 per yr	≥2 per yr		
		Consider severity and interval since last exacerbation. Frequency and severity may fluctuate over time for patients in any severity category.			
		Relative annual risk of exacerbations may be related to FEV_1.			
Recommended Step for Initiating Therapy		Step 1	Step 2	Step 3	Step 4 or 5
				and consider short course of oral systemic corticosteroids	
		In 2-6 wk, evaluate level of asthma control that is achieved and adjust therapy accordingly.			

The stepwise approach is meant to assist, not replace, the clinical decision-making required to meet individual patient needs.

Level of severity is determined by assessment of both impairment and risk. Assess impairment domain by patient's/caregiver's recall of previous 2 to 4 wk and spirometry. Assign severity to the most severe category in which any feature occurs.

At present, there are inadequate data to correspond frequencies of exacerbations with different levels of asthma severity. In general, more frequent and intense exacerbations (e.g., requiring urgent, unscheduled care, hospitalization, or ICU admission) indicate greater underlying disease severity. For treatment purposes, patients who had ≥2 exacerbations requiring oral systemic corticosteroids in the past year may be considered the same as patients who have persistent asthma, even in the absence of impairment levels consistent with persistent asthma.

EIB, Exercise-induced bronchospasm; *FEV_1,* forced expiratory volume in 1 second; *FVC,* forced vital capacity; *ICU,* intensive care unit.

From National Asthma Education and Prevention Program: *Expert panel report 3: guidelines for diagnosis and management of asthma,* National Institutes of Health, National Heart, Lung, and Blood Institute, August 2007, NIH publication 08-4051.

- ECG: Tachycardia, nonspecific ST-T wave changes are common during an asthma attack; may also show cor pulmonale, right bundle branch block, right axial deviation, counterclockwise rotation.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of triggering factors (e.g., salicylates, sulfites), environmental or occupational triggers
- Encouragement of regular exercise (e.g., swimming)
- Patient education regarding warning signs of an attack and proper use of medications (e.g., correct use of inhalers)
- Assess asthma control with use of validated questionnaires

GENERAL Rx

The 2007 NAEPP guidelines (see Tables 2 to 10) provide treatment options by age groups: 0 to 4 yr, 5 to 11 yr, and >12 yr. A step-up approach is described based on the severity of symptoms.

An approach to home management of acute asthma is described in Fig. E3. Short-acting beta-selective adrenergic agonists (SABAs) administered by inhalation is the most effective therapy for quick relief of asthmatic symptoms. They are recommended for use only as needed for relief of symptoms or before anticipated exposure to known triggers such as exercise. They should not be use as a single agent except for intermittent asthma symptoms. When symptoms become more frequent or more severe, step-up treatment with maintenance inhalers is recommended (see Table 4). Inhaled steroid is the mainstay of treatment for maintenance therapy. Other treatment options include long-acting beta-agonist (LABA), combination of inhaled steroids and LABA, leukotriene receptor antagonist (LTRA), cromolyn, zileuton, and theophylline. Oral corticosteroids are reserved as a last resort for maintenance therapy for recalcitrant cases. Various studies have showed some degree of benefit when adding LAMA to ICS + LABA in moderate to severe asthma. There are several corticosteroid/LABA combination inhalers available (fluticasone/salmeterol [Advair], budesonide/formoterol [Symbicort], mometasone/formoterol [Dulera], and ICS/LABA fluticasone furoate 200 mcg and vilanterol 25 mcg inhalation powder [Breo Ellipta]) on the market. None of these combinations is indicated for the initial treatment of asthma or for acute therapy of asthma symptoms. There is no evidence that one product is more effective than the others. A large study investigating the safety of LABA and ICS combination inhalers confirmed their

TABLE 3 Assessing Asthma Control and Adjusting Therapy in Youths ≥12 Yr and Adults

Components of Control		CLASSIFICATION OF ASTHMA CONTROL (≥12 YR)		
		Well Controlled	**Not Well Controlled**	**Very Poorly Controlled**
Impairment	Symptoms	≤2 days/wk	>2 days/wk	Throughout the day
	Nighttime awakenings	≤2×/mo	1-3x/wk	≥4/wk
	Interference with normal activity	None	Some limitation	Extremely limited
	Short-acting beta$_2$-agonist use for symptom control (not prevention of EIB)	≤2 days/wk	>2 days/wk	Several times per day
	FEV_1 or peak flow	>80% predicted/personal best	60%-80% predicted/personal best	<60% predicted/personal best
	Validated questionnaires			
	ATAQ	0	1-2	3-4
	ACQ	≤0.75*	≥1.5	N/A
	ACT™	≥20	16-19	≤15
Risk	Exacerbations requiring oral systemic corticosteroids	0-1 per yr	≥2 per yr	
		Consider severity and interval since last exacerbation		
	Progressive loss of lung function	Evaluation requires long-term follow-up care		
	Treatment-related adverse effects	Medication side effects can vary in intensity from none to very troublesome and worrisome. The level of intensity does not correlate to specific levels of control but should be considered in the overall assessment of risk.		
Recommended Action for Treatment		Maintain current step. Regular follow-up every 1-6 mo to maintain control. Consider step down if well controlled for at least 3 mo.	Step up 1 step and reevaluate in 2-6 wk. For side effects, consider alternative treatment options.	Consider short course of oral systemic corticosteroids. Step up 1-2 steps. Reevaluate in 2 wk. For side effects, consider alternative treatment options.

The stepwise approach is meant to assist, not replace, the clinical decision-making required to meet individual patient needs.
The level of control is based on the most severe impairment or risk category. Assess impairment domain by patient's recall of previous 2 to 4 wk and by spirometry or peak flow measures.
Symptom assessment for longer periods should reflect a global assessment, such as inquiring whether the patient's asthma is better or worse since the last visit.
At present, there are inadequate data to correspond frequencies of exacerbations with different levels of asthma control. In general, more frequent and intense exacerbations (e.g., requiring urgent, unscheduled care, hospitalization, or ICU admission) indicate poorer disease control. For treatment purposes, patients who had ≥2 exacerbations requiring oral systemic corticosteroids in the past year may be considered the same as patients who have not-well-controlled asthma, even in the absence of impairment levels consistent with not-well-controlled asthma.
Validated questionnaires for the impairment domain (the questionnaires do not assess lung function or the risk domain):

- ATAQ = Asthma Therapy Assessment Questionnaire
- ACQ = Asthma Control Questionnaire (user package may be obtained at www.qoltech.co.uk or juniper@qoltech.co.uk)
- ACT = Asthma Control Test™
- Minimal Important Difference: 1.0 for the ATAQ; 0.5 for the ACQ; not determined for the ACT

Before step up in therapy:

- Review adherence to medication, inhaler technique, environmental control, and comorbid conditions
- If an alternative treatment option was used in a step, discontinue and use the preferred treatment for that step

EIB, Exercise-induced bronchospasm; *FEV_1,* forced expiratory volume in 1 second; *ICU,* intensive care unit.
The Asthma Control Test is a trademark of QualityMetric Incorporated.
*ACQ values of 0.76-1.4 are indeterminate regarding well-controlled asthma.
From National Asthma Education and Prevention Program: *Expert panel report 3: guidelines for diagnosis and management of asthma,* National Institutes of Health, National Heart, Lung, and Blood Institute, August 2007, NIH publication 08-4051.

long-term safety and demonstrated a reduced risk of exacerbations and improved lung function, when compared with an equivalent dose of ICS alone.

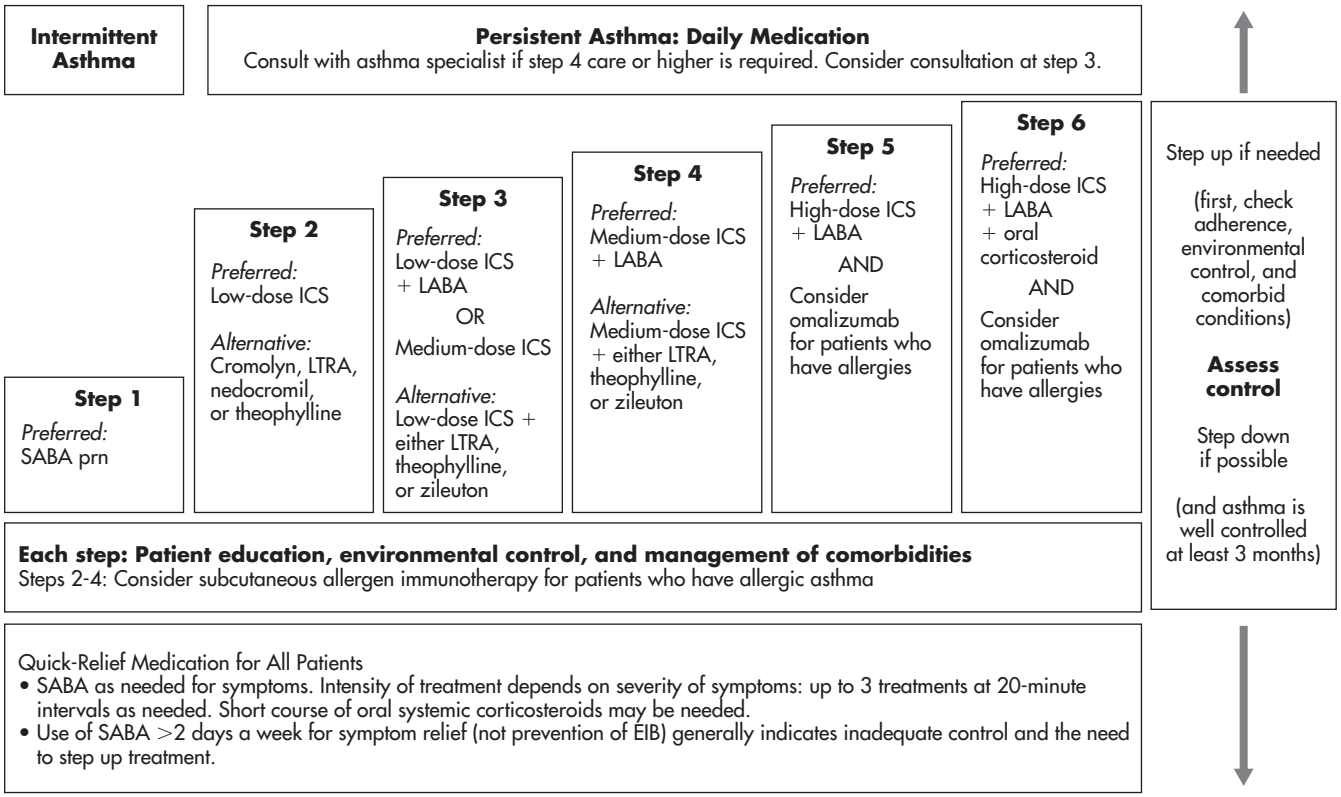
IMMUNOLOGIC TARGETS

- Dupilumab is a human monoclonal antibody to IL-4 and IL-13 FDA approved in patients 12 yr or older with moderate to severe asthma with an eosinophilic phenotype or with oral corticosteroid–dependent asthma.
- Mepolizumab (Nucala), an anti-interleukin-5 treatment, is approved by the FDA as an add-on for patients aged ≥12 yr with severe eosinophilic asthma that is uncontrolled on Step 4 treatment. Mepolizumab is a monoclonal antibody to IL-5 that has been shown to reduce exacerbations in patients with severe asthma who have blood eosinophil counts of 150/μL or greater. Mepolizumab is administered subcutaneously into the upper arm, thigh, or abdomen, 100 mg every 4 weeks. Hypersensitivity reactions have been reported with mepolizumab. In addition, herpes zoster infections have led to the recommendation of the administration of the varicella zoster vaccine to adults ages 50 or older 4 weeks prior to initiation of mepolizumab (unless they are at risk for disseminated zoster).
- Reslizumab, another anti-IL-5 monoclonal antibody, has a similar indication for eosinophilic asthma and uses a higher eosinophil cutoff (400) based on a greater predictive value for sputum eosinophilia. Benralizumab, a monoclonal anti-IL5 receptor alpha antibody, is an additional FDA-approved add-on treatment to consider for patients 12 yr or older with persistent severe eosinophilic asthma. It is administered as a subcutaneous injection every 4 wk for the first 3 doses then every 8 wk after that. Hypersensitivity reactions are more common than other anti-IL-5 antibodies and occur in about 3% of patients. Other adverse events include headache and pharyngitis.
- Omalizumab, an anti-IgE monoclonal antibody, is indicated for the treatment of moderate and severe persistent asthma with elevated IgE level, which is refractory to other treatment noted earlier. It is administered subcutaneously every 2 or 4 wk.

BRONCHIAL THERMOPLASTY

Selected patients with severe persistent asthma who have failed medical treatment may benefit from bronchial thermoplasty. This requires the insertion of a catheter via bronchoscopy and use of radiofrequency heat to reduce bronchial smooth muscle. Long-term follow-up data showed persistent reduction in asthma exacerbation and fewer ED visits over a period of 5 yr. FDA labeling is for "severe persistent asthma inadequately controlled on ICS + LABA."

TABLE 4 Stepwise Approach for Managing Asthma in Youths ≥12 Yr and Adults



The stepwise approach is meant to assist, not replace, the clinical decision-making required to meet individual patient needs.

If alternative treatment is used and response is inadequate, discontinue it and use the preferred treatment before stepping up.

Zileuton is a less desirable alternative due to limited studies as adjunctive therapy and the need to monitor liver function. Theophylline requires monitoring of serum concentration levels. In step 6, before oral systemic corticosteroids are introduced, a trial of high-dose ICS + LABA + either LTRA, theophylline, or zileuton may be considered, although this approach has not been studied in clinical trials.

Steps 1, 2, and 3 preferred therapies are based on Evidence A; step 3 alternative therapy is based on Evidence A for LTRA, Evidence B for theophylline, and Evidence D for zileuton. Step 5 preferred therapy is based on Evidence B. Step 6 preferred therapy is based on (EPR-2 1997) and Evidence B for omalizumab.

Immunotherapy for steps 2 to 4 is based on Evidence B for house-dust mites, animal danders, and pollens; evidence is weak or lacking for molds and cockroaches. Evidence is strongest for immunotherapy with single allergens. The role of allergy in asthma is greater in children than in adults.

Clinicians who administer immunotherapy or omalizumab should be prepared and equipped to identify and treat anaphylaxis that may occur.

TABLE 5 Classifying Asthma Severity and Initiating Treatment in Children 5-11 Yr (Assessing severity and initiating treatment in children who are not currently taking long-term control medications)

Components of Severity		CLASSIFICATION OF ASTHMA SEVERITY (5-11 YR OF AGE)			
			PERSISTENT		
		Intermittent	Mild	Moderate	Severe
Impairment	Symptoms	≤2 days/wk	>2 days/wk but not daily	Daily	Throughout the day
	Nighttime awakenings	≤23/mo	3-4×/mo	>1×/wk but not nightly	Often 7×/wk
	Short-acting beta$_2$-agonist use for symptom control (not prevention of EIB)	≤2 days/wk	>2 days/wk but not daily	Daily	Several times per day
	Interference with normal activity	None	Minor limitation	Some limitation	Extremely limited
	Lung function	Normal FEV_1 between exacerbations			
		FEV_1 >80% predicted	FEV_1 = >80% predicted	FEV_1 60%-80% predicted	FEV_1 <60% predicted
		FEV_1/FVC >85%	FEV_1/FVC >80%	FEV_1/FVC 75%-80%	FEV_1/FVC <75%
Risk	Exacerbations requiring oral systemic corticosteroids	0-1 per yr	≥2 per yr		
		Consider severity and interval since last exacerbation. Frequency and severity may fluctuate over time for patients in any severity category.			
		Relative annual risk of exacerbations may be related to FEV_1.			
Recommended Step for Initiating Therapy		Step 1	Step 2	Step 3, medium-dose ICS option	Step 3, medium-dose ICS option, or Step 4
				and consider short course of oral systemic corticosteroids	
		In 2-6 wk, evaluate level of asthma control that is achieved and adjust therapy accordingly.			

The stepwise approach is meant to assist, not replace, the clinical decision-making required to meet individual patient needs.

Level of severity is determined by both impairment and risk. Assess impairment domain by patient's/caregiver's recall of previous 2 to 4 wk and spirometry. Assign severity to the most severe category in which any feature occurs.

At present, there are inadequate data to correspond frequencies of exacerbations with different levels of asthma severity. In general, more frequent and intense exacerbations (e.g., requiring urgent, unscheduled care, hospitalization, or ICU admission) indicate greater underlying disease severity. For treatment purposes, patients who had ≥2 exacerbations requiring oral systemic corticosteroids in the past year may be considered the same as patients who have persistent asthma, even in the absence of impairment levels consistent with persistent asthma.

EIB, Exercise-induced bronchospasm; *FEV_1,* forced expiratory volume in 1 second; *FVC,* forced vital capacity; *ICS,* inhaled corticosteroid; *ICU,* intensive care unit.

From National Asthma Education and Prevention Program: *Expert panel report 3: guidelines for diagnosis and management of asthma,* National Institutes of Health, National Heart, Lung, and Blood Institute, August 2007, NIH publication 08-4051.

TABLE 6 Assessing Asthma Control and Adjusting Therapy in Children 5-11 Yr

Components of Control		CLASSIFICATION OF ASTHMA CONTROL (5-11 YR OF AGE)		
		Well Controlled	Not Well Controlled	Very Poorly Controlled
Impairment	Symptoms	≤2 days/wk but not more than once on each day	>2 days/wk or multiple times on ≤2 days/wk	Throughout the day
	Nighttime awakenings	≤1×/mo	≥2×/mo	≥2×/wk
	Interference with normal activity	None	Some limitation	Extremely limited
	Short-acting beta$_2$-agonist use for symptom control (not prevention of EIB)	≤2 days/wk	>2 days/wk	Several times per day
	Lung function			
	FEV_1 or peak flow	>80% predicted/personal best	60%-80% predicted/personal best	<60% predicted/personal best
	FEV_1/FVC	>80% predicted	75%-80%	<75% predicted
Risk	Exacerbations requiring oral systemic corticosteroids	0-1 per yr	≥2 per yr	
		Consider severity and interval since last exacerbation		
	Reduction in lung growth	Evaluation requires long-term follow-up care		
	Treatment-related adverse effects	Medication side effects can vary in intensity from none to very troublesome and worrisome. The level of intensity does not correlate to specific levels of control but should be considered in the overall assessment of risk.		
Recommended Action for Treatment		Maintain current step. Regular follow-up every 1-6 mo. Consider step down if well controlled for at least 3 mo.	Step up 1 step and reevaluate in 2-6 wk. For side effects, consider alternative treatment options.	Consider short course of oral systemic corticosteroids. Step up 1-2 steps. Reevaluate in 2 wk. For side effects, consider alternative treatment options.

The stepwise approach is meant to assist, not replace, the clinical decision-making required to meet individual patient needs.

The level of control is based on the most severe impairment or risk category. Assess impairment domain by patient's/caregiver's recall of previous 2 to 4 wk and by spirometry or peak flow measures. Symptom assessment for longer periods should reflect a global assessment such as inquiring whether the patient's asthma is better or worse since the last visit.

At present, there are inadequate data to correspond frequencies of exacerbations with different levels of asthma control. In general, more frequent and intense exacerbations (e.g., requiring urgent, unscheduled care, hospitalization, or ICU admission) indicate poorer disease control. For treatment purposes, patients who had ≥2 exacerbations requiring oral systemic corticosteroids in the past year may be considered the same as patients who have persistent asthma, even in the absence of impairment levels consistent with persistent asthma.

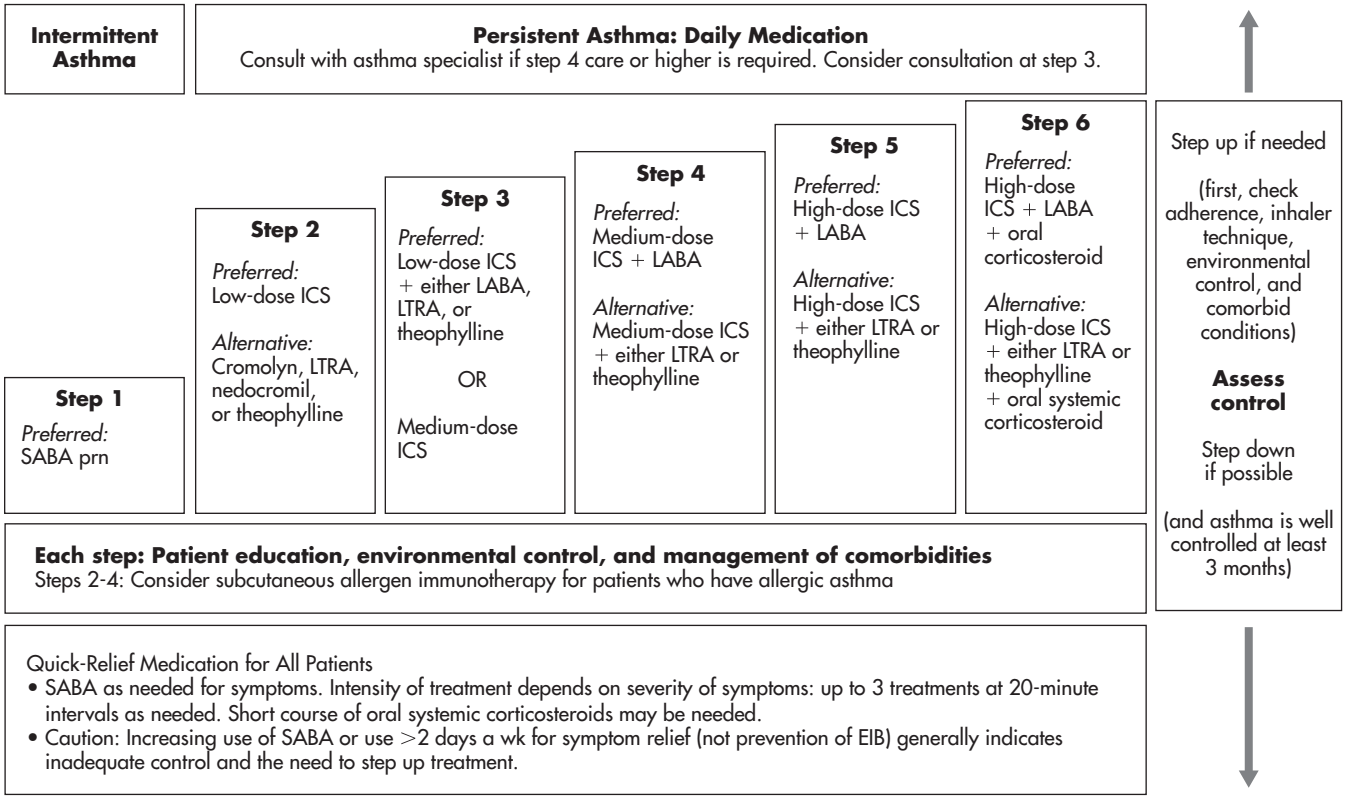
Before step up in therapy:

- Review adherence to medications, inhaler technique, environmental control, and comorbid conditions.
- If an alternative treatment option was used in a step, discontinue it and use preferred treatment for that step.

EIB, Exercise-induced bronchospasm; *FEV_1,* forced expiratory volume in 1 second; *FVC,* forced vital capacity; *ICU,* intensive care unit.

From National Asthma Education and Prevention Program: *Expert panel report 3: guidelines for diagnosis and management of asthma,* National Institutes of Health, National Heart, Lung, and Blood Institute, August 2007, NIH publication 08-4051.

TABLE 7 Stepwise Approach for Managing Asthma in Children 5-11 Yr



The stepwise approach is meant to assist, not replace, the clinical decision-making required to meet individual patient needs.
If alternative treatment is used and response is inadequate, discontinue it and use the preferred treatment before stepping up.
Theophylline is a less desirable alternative due to the need to monitor serum concentration levels.
Step 1 and step 2 medications are based on Evidence A. Step 3 ICS 1 adjunctive therapy and ICS are based on Evidence B for efficacy of each treatment and extrapolation from comparator trials in older children and adults—comparator trials are not available for this age group; steps 4-6 are based on expert opinion and extrapolation from studies in older children and adults. Immunotherapy for steps 2 to 4 is based on Evidence B for house-dust mites, animal danders, and pollens; evidence is weak or lacking for molds and cockroaches. Evidence is strongest for immunotherapy with single allergens. The role of allergy in asthma is greater in children than in adults. Clinicians who administer immunotherapy should be prepared and equipped to identify and treat anaphylaxis that may occur.

EIB, Exercise-induced bronchoconstriction; *ICS,* inhaled corticosteroid; *LABA,* inhaled long-acting beta$_2$-agonist; *LTRA,* leukotriene receptor antagonist; *prn,* as necessary; *SABA,* inhaled short-acting beta$_2$-agonist.
From National Asthma Education and Prevention Program: *Expert panel report 3: guidelines for diagnosis and management of asthma,* National Institutes of Health, National Heart, Lung, and Blood Institute, August 2007, NIH publication 08-4051.

OTHER MEDICATIONS

Tiotropium (Spiriva) has been used for decades as first-line treatment for COPD. This LAMA is now approved for a second indication for the treatment of asthma and is included in the most recent (2018) Global Initiative for Asthma (GINA) guidelines as a possible add-on at step 4. A systematic review including over 7000 patients demonstrated the use of LAMA compared with placebo as an add-on to inhaled corticosteroids was associated with lower risk of exacerbation. Adding LAMA to a dual LABA-ICS regimen was not shown to reduce exacerbation rates but can improve lung function.

Azithromycin: The AZISAST Trial randomized 109 patients on high-dose ICS/LABA (step 4 or 5 per GINA guidelines) to maintenance therapy with azithromycin or placebo. Overall, there was no benefit seen with azithromycin therapy with regard to any of the outcomes tested. However, subgroup analysis showed that patients with noneosinophilic asthma had fewer exacerbations. More data are needed, but this result suggests azithromycin may be an effective option for the neutrophilic/Th-1 phenotype (COPD is also neutrophilic).

Immunosuppressants such as methotrexate can decrease long-term steroid requirements; however, they have significant side effects, and there is no evidence of persistent therapeutic effect after discontinuing them.

TREATMENT OF SEVERE ASTHMA (ETS/ETA GUIDELINES)

- The American Thoracic Society (ATS) classification of "severe asthma" refers to patients who require high-dose inhaled or near-continuous oral glucocorticoid treatment to maintain asthma control.
- In patients who do not achieve adequate control with the combination of a high-dose inhaled glucocorticoid and LABA, an additional controller medication such as an antileukotriene agent is recommended (tiotropium or theophylline).
- For patients with atopic severe asthma who have a serum IgE level of 30 to 700 IU/ml and documented sensitivity to a perennial allergen, recommend adding omalizumab.
- For patients with severe asthma, frequent exacerbations, and an eosinophilic phenotype despite guideline-based therapy, consider add-on therapy with one of the anti-interleukin (IL)-5 antibodies, mepolizumab, reslizumab, or benralizumab.
- Bronchial thermoplasty is approved for use in selected adults with severe asthma that is not well controlled with inhaled glucocorticoids and LABAs.
- Potential alternative and experimental therapies include immunomodulatory therapy and macrolide antibiotics.[a]

[a]Recent trials (AMAZES) in patients who have symptomatic asthma despite inhaled maintenance therapy have shown that azithromycin 500 mg 3 times/week reduced exacerbations and improved quality of life.

TABLE 8 Classifying Asthma Severity and Initiating Treatment in Children 0-4 Yr (Assessing severity and initiating treatment in children who are not currently taking long-term control medications)

Components of Severity		CLASSIFICATION OF ASTHMA SEVERITY (0-4 YR OF AGE)			
			PERSISTENT		
		Intermittent	Mild	Moderate	Severe
Impairment	Symptoms	≤2 days/wk	>2 days/wk but not daily	Daily	Throughout the day
	Nighttime awakenings	0	1-2×/mo	3-4×/mo	>1×/wk
	Short-acting $beta_2$-agonist use for symptom control (not prevention of EIB)	≤2 days/wk	>2 days/wk but not daily	Daily	Several times per day
	Interference with normal activity	None	Minor limitation	Some limitation	Extremely limited
Risk	Exacerbations requiring oral systemic corticosteroids	0-1 per yr	≥2 exacerbations in 6 mo requiring oral systemic corticosteroids, or ≥4 wheezing episodes/1 yr lasting >1 day AND risk factors for persistent asthma.		
		Consider severity and interval since last exacerbation. Frequency and severity may fluctuate over time.			
		Exacerbations of any severity may occur in patients in any severity category.			
Recommended Step for Initiating Therapy		Step 1	Step 2	Step 3 and consider short course of oral systemic corticosteroids	
		In 2-6 wk, depending on severity, evaluate level of asthma control that is achieved. If no clear benefit is observed in 4-6 wk, consider adjusting therapy or alternative diagnoses.			

The stepwise approach is meant to assist, not replace, the clinical decision-making required to meet individual patient needs.

Level of severity is determined by assessment of both impairment and risk. Assess impairment domain by patient's/caregiver's recall of previous 2-4 wk. Symptom assessment for longer periods should reflect a global assessment such as inquiring whether the patient's asthma is better or worse since the last visit. Assign severity to the most severe category in which any feature occurs.

At present, there are inadequate data to correspond frequencies of exacerbations with different levels of asthma severity. For treatment purposes, patients who had ≥2 exacerbations requiring oral systemic corticosteroids in the past six months, or ≥4 wheezing episodes in the past year, and who have risk factors for persistent asthma may be considered the same as patients who have persistent asthma, even in the absence of impairment levels consistent with persistent asthma.

TABLE 9 Assessing Asthma Control and Adjusting Therapy in Children 0-4 Yr of Age

Components of Control		CLASSIFICATION OF ASTHMA CONTROL (0-4 YR OF AGE)		
		Well Controlled	Not Well Controlled	Very Poorly Controlled
Impairment	Symptoms	≤2 days/wk	>2 days/wk	Throughout the day
	Nighttime awakenings	≤13/mo	>1×/mo	>1×/wk
	Interference with normal activity	None	Some limitation	Extremely limited
	Short-acting $beta_2$-agonist use for symptom control (not prevention of EIB)	≤2 days/wk	>2 days/wk	Several times per day
Risk	Exacerbations requiring oral systemic corticosteroids	0-1 per yr	2-3 per yr	>3 per yr
	Treatment-related adverse effects	Medication side effects can vary in intensity from none to very troublesome and worrisome. The level of intensity does not correlate to specific levels of control but should be considered in the overall assessment of risk.		
Recommended Action for Treatment		Maintain current step. Regular follow-up every 1-6 mo. Consider step down if well controlled for at least 3 mo.	Step up 1 step. Reevaluate in 2-6 wk. If no clear benefit in 4-6 wk, consider alternative diagnoses or adjusting therapy. For side effects, consider alternative treatment options.	Consider short course of oral systemic corticosteroids. Step up 1-2 steps. Reevaluate in 2 wk. If no clear benefit in 4-6 wk, consider alternative diagnoses or adjusting therapy. For side effects, consider alternative treatment options.

The stepwise approach is meant to assist, not replace, the clinical decision-making required to meet individual patient needs.

The level of control is based on the most severe impairment or risk category. Assess impairment domain by caregiver's recall of previous 2 to 4 wk. Symptom assessment for longer periods should reflect a global assessment such as inquiring whether the patient's asthma is better or worse since the last visit.

At present, there are inadequate data to correspond frequencies of exacerbations with different levels of asthma control. In general, more frequent and intense exacerbations (e.g., requiring urgent, unscheduled care, hospitalization, or ICU admission) indicate poorer disease control. For treatment purposes, patients who had ≥2 exacerbations requiring oral systemic corticosteroids in the past year may be considered the same as patients who have not-well-controlled asthma, even in the absence of impairment levels consistent with not-well-controlled asthma.

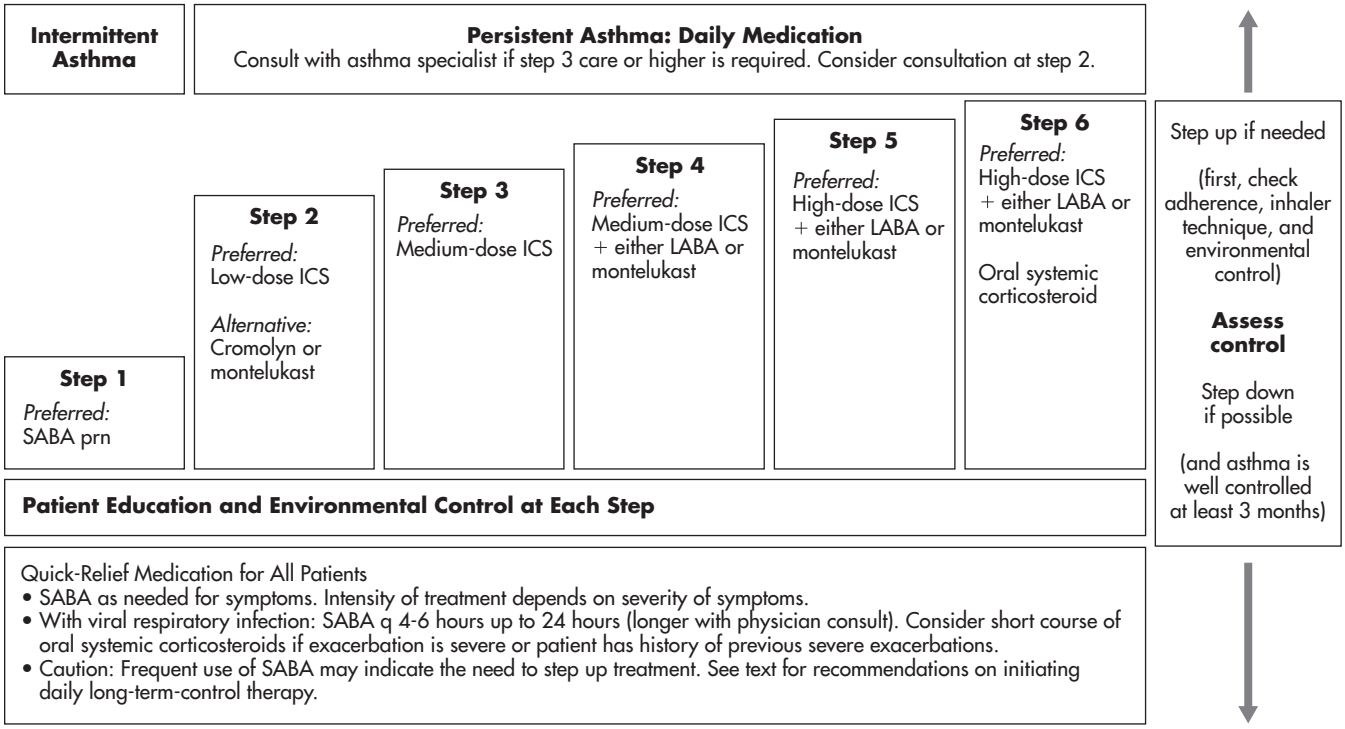
Before step up in therapy:

- Review adherence to medications, inhaler technique, and environmental control.
- If an alternative treatment option was used in a step, discontinue it and use preferred treatment for that step.

EIB, Exercise-induced bronchospasm; *ICU,* intensive care unit.

From National Asthma Education and Prevention Program: *Expert panel report 3: guidelines for diagnosis and management of asthma,* National Institutes of Health, National Heart, Lung, and Blood Institute, August 2007, NIH publication 08-4051.

TABLE 10 Stepwise Approach for Managing Asthma in Children 0-4 Yr



The stepwise approach is meant to assist, not replace, the clinical decision-making required to meet individual patient needs. If alternative treatment is used and response is inadequate, discontinue it and use the preferred treatment before stepping up.
If clear benefit is not observed within 4 to 6 wk and patient/family medication technique and adherence are satisfactory, consider adjusting therapy or alternative diagnosis.
Studies on children 0 to 4 yr are limited. Step 2 preferred therapy is based on Evidence A. All other recommendations are based on expert opinion and extrapolation from studies in other children.
This information is directly abstracted from the 2007 NAEPP *Expert Panel Report 3: Guidelines for the Diagnosis and Management of Asthma* and is not intended to promote or endorse any of the listed products.
ICS, Inhaled corticosteroid; *LABA,* inhaled long-acting beta$_2$-agonist; *prn,* as necessary; *SABA,* inhaled short-acting beta$_2$-agonist.
From National Asthma Education and Prevention Program: *Expert panel report 3: guidelines for diagnosis and management of asthma,* National Institutes of Health, National Heart, Lung, and Blood Institute, August 2007, NIH publication 08-4051.

- In the future, treatments tailored to asthma phenotypes may improve asthma outcomes.

Treatment of status asthmaticus is as follows:

- Oxygen generally started at 2 to 4 L/min by nasal cannula or Venti-Mask at 40% Fio_2; further adjustments are made according to oxygen saturations.
- Bronchodilators: Initiate treatment with high-dose SABA plus ipratropium bromide administered by means of a nebulizer every 20 min. Use of a metered-dose inhaler with valved holding chamber may be acceptable for patients with mild-to-moderate exacerbations.
- Albuterol nebulizer solution (0.63 mg/3 ml, 1.25 mg/3 ml, 2.5 mg/3 ml, or 5.0 mg/ml): 2.5 to 5 mg every 20 min over the first hr, then 2.5 to 10 mg every 1 to 4 hr as needed or 10 to 15 mg/hr continuously. Other useful medications are levalbuterol nebulizer solution (0.31 mg/3 ml, 0.63 mg/3 ml, 1.25 mg/3 ml) and ipratropium nebulizer solution (0.25/ml [0.025%]).
- Corticosteroids:
  1. Early administration is advised, particularly in patients using steroids at home.
  2. Patients may be started on systemic corticosteroids; methylprednisolone, prednisone, or prednisolone may be used. Dose range is from 40-80 mg/day in one or two divided doses, generally given until peak expiratory flow reaches 70% of predicted value.
  3. Generally for corticosteroid courses <1 wk there is no need to taper the dose.
- IV hydration: Judicious use is necessary to avoid congestive heart failure in elderly patients. Aggressive IV hydration is not recommended.
- IV antibiotics are indicated when there is suspicion of bacterial infection (e.g., infiltrate on chest radiograph, fever, or leukocytosis).
- Intubation and mechanical ventilation are indicated when previous measures fail to produce significant improvement. Table 11 summarizes treatment of life-threatening asthma.
- Discharge home from the emergency department is appropriate if the FEV_1 or PEF after treatment is 70% or greater of the personal best or predicted value and if there is sustained improvement in lung function and symptoms for at least 1 hr.

REFERRAL

Box 4 describes indications for referral to an asthma specialist.

PEARLS & CONSIDERATIONS

COMMENTS

- The differentiation of asthma from COPD can be challenging. A history of atopy and intermittent, reactive symptoms points toward a diagnosis of asthma, whereas smoking and advanced age are more indicative of COPD. Spirometry is useful in distinguishing asthma from COPD.
- In all asthma patients it is important to treat or prevent comorbid conditions (e.g., rhinosinusitis, vocal cord dysfunction, gastroesophageal reflux disease). However, despite the presumed association between asthma and GERD, trials of PPIs in patients with poorly controlled asthma did not reveal any beneficial effects.
- Inhaled low-dose corticosteroids are the single most effective therapy for adult patients with asthma who require more than an occasional use of SABAs to control their asthma.
- Stepping down inhaled corticosteroids after asthma is well controlled now has level A evidence.
- Leukotriene modifiers/receptor agonists represent a reasonable alternative in adults

TABLE 11 Summary of Treatment for Life-Threatening Asthma

Treatment	Dose and Frequency	Comments
Oxygen	1-3 L/min by nasal cannula Goal is to maintain oxygen saturation (Spo_2) >92% Use heated cascade humidifier to avoid dry air–induced bronchoconstriction	Transient drop in O_2 tension with beta-adrenergic therapy Avoid hyperoxia (may be associated with hypercarbia)
Bronchodilators		
$Beta_2$-selective agonists: Albuterol or salbutamol, levalbuterol	*Albuterol*: 2.5-5 mg (0.5-1 ml of 0.5% solution in 5 ml of normal saline) by nebulizer every 20 min for 3 doses total (for optimal delivery, dilute aerosols to a minimum of 3 ml at gas flow of 6-8 L/min), followed by 2.5-10 mg q1-4h as needed, or 10-15 mg/h continuously; titration based on response and severity of symptoms *Albuterol MDI*, delivered with a spacer (each spacer dose takes 1-2 min; 90 μg/puff), 4-8 puffs every 20 min for 4 h, then q4h as needed *Albuterol*: 5-7.5 mg by jet nebulizer (each treatment takes 15-20 min) *Levalbuterol* (0.63 mg/3 ml and 1.25 mg/3 ml nebulizer): 1.25-2.5 mg every 20 min for 3 doses total, then 1.25-5 mg q1-4h as needed, or 5-7.5 mg/h continuous nebulization *Levalbuterol MDI* (45 μg/puff): 4-8 puffs every 20 min for 4 h, followed by q1-4h as needed	$Beta_2$-selective agonists are the cornerstone of therapy Continuous nebulization used for a majority of severely ill patients In study of continuous vs. intermittent therapy in severe exacerbations (excluding life-threatening asthma), no difference noted in pulmonary function improvement or need for hospitalization Lower frequency of side effects with continuous treatment Watch for hypokalemia, tremors, tachycardia, and lactic acidosis Oral or parenteral route: Loss of $beta_2$-selectivity MDI: 4 puffs of albuterol (0.36 mg) = 2.5 mg of albuterol nebulization Levalbuterol 0.63 mg = racemic albuterol 1.25 mg for efficacy and side effects *Intubated patients*: Nebulizers are less efficient in delivering doses to lower airways (6-10%) than MDIs (11%)
Epinephrine	*Subcutaneous epinephrine* dose for adults: 0.3-0.5 ml of a 1:1000 dilution (1 mg/ml), depending on age and weight; repeat every 20 min for 3 doses total	
Terbutaline	*Subcutaneous terbutaline*, 0.25 mg; repeat every 20 min for 3 doses total	Terbutaline is the parenteral agent of choice in pregnancy For refractory life-threatening asthma: Intravenous epinephrine (high risk for cardiac events, infarction, and arrhythmias) or racemic epinephrine may be considered
Anticholinergics		
Ipratropium (for acute severe asthma warranting visit to emergency department)	*Ipratropium bromide*: 0.5 mg by nebulizer (0.25 mg/ml) every 20 min for 3 doses, then q2-4h as needed *Ipratropium MDI* (0.018 mg/puff): 4-8 puffs per treatment every 20 min for up to 3 h *Combinations*: Albuterol (2.5 mg/3 ml) + ipratropium (0.5 mg/3 ml): 3 ml every 20 min for 3 doses total, then as needed MDI delivering albuterol 90 μg + ipratropium 18 μg: 8 puffs every 20 min for up to 3 h	Ipratropium: Onset of action is slow (20 min), peak effectiveness at 60-90 min, no systemic side effects, improved lung function and reduced recovery time Use a handheld mouthpiece nebulizer (contamination of the ocular area with precipitation of narrow-angle glaucoma may occur if facemask is used for delivery of anticholinergic agent) Ipratropium may be combined with nebulized albuterol dose in the emergency room; no proven benefit shown in hospitalized patients
Corticosteroids: Prednisone, prednisolone, methylprednisolone	40-80 mg/day in 1 or 2 divided doses until peak expiratory flow reaches 70% of predicted or personal best FEV_1 or PEFR <50% Methylprednisolone 40 mg IV q6h OR Hydrocortisone 200 mg IV	No advantage of higher doses No advantage of IV therapy over oral if absorption and gut transit are not impaired Total steroid course: 3-10 days, <1 wk; no need to taper steroids Inhaled steroids can be started at any time
Heliox	Helium-oxygen mixture (80-20 or 70-30) Routine use cannot be recommended at this time	Improves O_2 and aerosolized medication delivery to distal lung Decreases flow turbulence and resistance Lower gas density facilitates exhalation, reduces air trapping and intrinsic PEEP Improves pulmonary function in subgroup of patients with most severe airflow obstruction
Magnesium sulfate	2 g IV given over 20 min; may repeat Monitor magnesium levels Avoid in renal insufficiency	Bronchodilatation from inhibition of the calcium channel and decreased acetylcholine release IV and inhaled or nebulized magnesium sulfate improves pulmonary function in acute severe asthma IV magnesium widely used as adjunct therapy

FEV_1, Forced expiratory flow in 1 second; *IV*, intravenous; *MDI*, metered-dose inhaler; *PEEP*, positive end-expiratory pressure; *PEFR*, peak expiratory flow rate.
From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 4, Philadelphia, 2014, Elsevier.

unable or unwilling to use corticosteroids; however, these agents are less effective than monotherapy with inhaled corticosteroids.
- Use of LABAs alone without use of a long-term asthma medication, such as an inhaled corticosteroid, is contraindicated. LABAs should also not be used in patients whose asthma is adequately controlled on low- or medium-dose inhaled corticosteroids. Continued use of LABAs may cause down-regulation of the beta-2 receptor with loss of the bronchoprotective effect from rescue therapy with a SABA.
- Patients who remain symptomatic despite inhaled corticosteroids benefit from the addition of LABAs. Trials in patients with poorly controlled asthma despite the use of inhaled glucocorticoids and LABAs have shown that the addition of tiotropium, a long-acting anticholinergic bronchodilator approved for treatment of COPD, increased the time to the first severe exacerbation and provided modest sustained bronchodilation.
- Therapy with systemic corticosteroids accelerates the resolution of acute asthma and reduces the risk of relapse. There is no evidence that doses >50-100 mg prednisone equivalent are beneficial.
- In patients with allergies and elevated serum immunoglobulin (Ig) E levels, use of anti-IgE therapy is beneficial.
- Bronchial thermoplasty should be considered in selective patients with severe persistent asthma with recurrent exacerbations or ED visits. Biologic modifiers of the Th2 immune pathways (neutralizing monoclonal antibodies, receptor antagonists, soluble receptors) are potential options for the development of new treatments of severe asthma. Adjunct therapies for bronchospasm are summarized in Table 12.
- The response to treatment for asthma is characterized by wide individual variability. A functional glucocorticoid-induced transcript 1 gene *(GLCCI1)* variant is associated with substantial decrements in the response to inhaled glucocorticoids in patients with asthma. Another potential cause of the variability in response to treatment is heterogeneity in the role of interleukin-13 expression in the clinical asthma phenotype. Patients with asthma who have a certain biochemical signature are more likely to respond to an anti–interleukin-13 monoclonal antibody than those without such a signature. Identification of genetic variants can eventually lead to personalized asthma treatment. Failure of pharmacologic treatment is often due to uncontrolled comorbid conditions (tobacco, allergic rhinitis, pollutants), poor inhaler technique, or lack of adherence to prescribed medication.

BOX 4 Possible Indications for Referral to an Asthma Specialist

- Severe, acute asthma that has caused loss of consciousness, hypoxia, respiratory failure, convulsions, or near death
- Poorly controlled asthma as indicated by admission to a hospital, frequent need for emergency care, need for oral corticosteroids, absence from school or work, disruption of sleep, interference with quality of life
- Severe, persistent asthma requiring step 4 care (consider for patients who require step 3 care)
- Patient <3 yr who requires step 3 or 4 care (consider for patient <3 yr who requires step 2 care)
- Requirement for continuous oral corticosteroids or high-dose inhaled corticosteroids or more than two short courses of oral corticosteroids within 1 yr
- Need for additional diagnostic testing such as allergy skin testing, rhinoscopy, provocative challenge, complete pulmonary function testing, bronchoscopy
- Consideration for immunotherapy
- Need for additional education regarding asthma, complications of asthma and treatment of asthma, problems with adherence to management recommendations, or allergen avoidance
- Uncertainty of diagnosis
- Complications of asthma, including sinusitis, nasal polyposis, aspergillosis, severe rhinitis, vocal cord dysfunction, gastroesophageal reflux

TABLE 12 Adjunct Therapies for Bronchospasm

Nontraditional Therapy for Severe Bronchospasm	Comments
Intravenous beta$_2$-agonists	No data show any benefit in adding IV agent to nebulization Avoid IV isoproterenol owing to danger of myocardial toxicity
Oral or IV leukotriene receptor antagonists (LTRAs): Montelukast 10 mg oral daily, zafirlukast	Rapid bronchodilation in impending respiratory failure Improves pulmonary function within 10 min Oral LTRAs can be added as an adjunct in severe asthma
Noninvasive positive-pressure ventilation (NPPV)	NPPV reduces the need for endotracheal intubation in severe asthma exacerbation
Inhaled nitric oxide (NO) (adding 15 ppm to the inspiratory circuit)	Rapid improvement in ventilated patients with asthma refractory to medical treatment
Omalizumab (anti-IgE antibody)	Role in acute asthma is unstudied Improves asthma control in allergic asthmatics
General anesthetic agents: Isoflurane or halothane anesthesia IV thiopental, IV propofol, IV ketamine	Propofol relaxes the smooth muscles in arteries and veins and has bronchodilator effect
Plasma exchange (during pregnancy) Pumpless extracorporeal carbon dioxide removal Extracorporeal life support (ECLS)	Case reports of adjunct therapies; used as salvage therapy for life-threatening asthma
Glucagon	Rapid smooth muscle relaxant, short half-life; small study report
Nebulized DNase (dornase 2.5 mg via tracheal tube)	Case report of use in pregnant patient with rapid improvement
Bronchial lavage	Anecdotal reports: Exacerbates auto-PEEP, decreases oxygenation

IgE, Immunoglobulin E; *IV,* intravenous; *PEEP,* positive end-expiratory pressure.

Asthma-COPD Overlap Syndrome

BASIC INFORMATION

DEFINITION

The asthma and chronic obstructive pulmonary disease (COPD) overlap syndrome (ACOS) is a recently recognized clinical entity of important significance. It identifies a subgroup of smokers with COPD that shares some pathogenic and inflammatory characteristics with asthma and that tends to have a more severe disease phenotype than just COPD alone. It has been defined as either:

- Asthma with partially reversible airflow obstruction with or without emphysema or reduced carbon monoxide diffusing capacity (DLco) to <80% predicted
- Chronic obstructive pulmonary disease (COPD) with emphysema accompanied by reversible or partially reversible airflow obstruction, with or without environmental allergies or reduced DLco

SYNONYMS

Bronchospasm
Reactive airway disease
Asthmatic bronchitis
Hyperreactive airways
Chronic obstructive pulmonary disease

ICD10-CM CODES

J45	Asthma
J42	Unspecified chronic bronchitis
J43	Emphysema
J44	COPD
J44.9	COPD, unspecified
M35.1	Other overlap syndromes

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- COPD afflicts 14.2 million adults (a prevalence of 1 in 5) in the U.S.
- Twenty-five million Americans (18 million adults and 7 million children) have asthma (prevalence of 1 in 12 adults).
- The prevalence of bronchial hyperresponsiveness among patients with COPD has been reported to be 60%.
- Reversibility of airway obstruction is frequently present in COPD as well; in two studies, reversibility was observed in up to 44% and 50% of patients with COPD.
- Among published studies, persons with ACOS have worse lung function, more respiratory symptoms, and a lower health-related quality of life than those with either disease alone. Those with ACOS are reported to experience more frequent health care utilization and more severe impairment than persons with COPD or asthma alone.
- In a recent study, 15-yr mortality for ACOS was similar to that for COPD and worse than that for asthma and healthy controls. ACOS had a significant impact on physical performance, functional ability, and health-related quality of life.
- The prevalence of ACOS is between 15% and 25% in an adult population of obstructive airway diseases. ACOS is also more prevalent in the elderly, African Americans, and among individuals with greater disease severity.
- Epidemiologic studies report an estimated prevalence of 20%.

PREDOMINANT SEX AND AGE:

- Sex: In a large, population-based sample, women were more likely than men to report ACOS.
- Age: The prevalence of overlap syndrome has been shown to increase with age (>60-70), which may reflect that with time asthmatics may develop fixed airway obstruction.
- Race: No published predilection for race/ethnicity noted.

GENETICS:

- No known genetic basis described. Genetic linkage studies and genome-wide association (GWA) studies have been of limited value in characterizing a link between asthma and COPD.
- Postma, et al. (2015) evaluated the paucity of GWA studies, assessing overlap syndrome and the focus on clearly defined outcomes that do not include overlap and that hamper the current insight that genetic studies provide. However, Hardin et al (2014) showed that the two most significant associations among non-Hispanic white overlap subjects include variants from the *CSMD1* gene, which has been associated with emphysema, and within the *SOX5* gene, which has previously been associated with COPD and may play a role in lung development.
- In a meta-analysis across the non-Hispanic white and African American groups, several variants in the *GPR65* gene were identified that were associated with the overlap syndrome.

RISK FACTORS:

- Smoking
- Atopy
- Genetics
- Childhood asthma
- Older age
- Allergies
- Infections (rhinovirus, influenza, mycoplasma)
- Higher body mass index (BMI)
- Patients with ACOS have the combined risk factors of smoking and atopy and are generally younger than patients with COPD

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Physical examination:

- May be normal
- Wheezing, rhonchi
- Hoover sign
- In severe cases, decreased airway entry, abdominal retractions, accessory muscle use, abdominal muscle use

Clinical presentation:

- Wheezing
- Shortness of breath
- Chest tightness
- History of repeated respiratory infections
- Chronic cough (typically productive)
- Episodic symptoms instigated by certain triggers (odors, temperatures, allergens)
- Decreased exercise tolerance

ETIOLOGY

- The pathophysiology of asthma involves a complex interaction among various environmental and genetic factors.
- Cigarette smoking interacts with the inflammation and remodeling that occur in asthma and COPD.
- No genetic basis identified thus far.

DIAGNOSIS

ACOS should be considered when "a similar number of features listed for asthma and COPD are present." This definition for ACOS is not yet very specific because it is recognized that a more detailed classification of patients with overlapping features of asthma and COPD is needed. Studies performed so far have generally based the diagnosis of ACOS on the pattern of symptoms, the presence of incompletely reversible airflow obstruction in ex- or current smokers or patients with asthma, the degree of bronchodilator reversibility, and bronchial hyperresponsiveness.

DIFFERENTIAL DIAGNOSIS

- COPD
- Asthma
- Central airway obstruction
- Bronchiectasis
- Heart failure
- Obliterative bronchiolitis

WORKUP

- Patients must have demonstrated either one of these to be diagnosed with "overlap syndrome":
  1. Reversible airflow: Increase in FEV1 or forced vital capacity (FVC) by ≥200 ml and 12% postbronchodilator challenge
  2. Airway hyperresponsiveness (AHR): A positive methacholine challenge test
- Asthma defined by the Global Initiative for Asthma (GINA) executive summary criteria, as a clinical syndrome with "variable airflow obstruction within the lung that is often reversible either spontaneously or with treatment"
- COPD according to the American Thoracic Society/European Respiratory Society (ATS/ERS) joint task force: "a preventable and treatable disease state characterized by airflow limitation that is not fully reversible"

LABORATORY TESTS

- Arterial blood gas (ABG)
- Complete blood count (CBC)
- Spirometry
- Methacholine challenge
- Peak expiratory flow rate (PEFR)
- Serum immunoglobulin E
- Sputum
- Allergy testing

IMAGING STUDIES

- Chest x-ray
- Chest CT scan
- ECG

Rx TREATMENT

There is little information about the response of ACOS patients to most of the current pharmacologic therapies because they have been systematically excluded from both COPD and asthma pharmacologic trials. The main interest in differentiating ACOS from COPD lies in the different response to inhaled corticosteroids (ICS). Some studies demonstrate that patients with COPD and eosinophilic inflammation treated with ICS present a significant improvement clinically and objectively by spirometry.

NONPHARMACOLOGIC THERAPY

- Avoidance of environmental or occupational trigger factors
- Patient education regarding warning signs of an attack and proper use of medications (e.g., correct use of inhalers)
- Pulmonary rehabilitation

ACUTE GENERAL Rx

- At present, there are no randomized clinical trial data to help guide therapeutic interventions in overlap syndrome.
- Treatment typically is directed toward management of symptoms.
- For dynamic obstruction and/or hyperinflation, bronchodilators may provide the greatest benefit.
- Whether long-acting muscarinic antagonists (LAMAs) alone or in combination with long-acting beta-agonists (LABAs) are appropriate in overlap syndrome remains to be elucidated.
- For patients in whom bronchospasm is demonstrated, bronchodilators and ICSs are reasonable options.
- Clinical trials have shown efficacy for fluticasone furoate/vilanterol combination (the first once-daily ICS/LABA) versus twice-daily fluticasone propionate/salmeterol; it can provide substantial improvement in lung functions in a population of ACOS, indicating that this combination should be considered for the regular treatment of ACOS.
- The 2018 GINA guideline supports consideration of including an ICS in treatment regimens of patients with ACOS. A well-designed case-control trial demonstrated newly prescribed ICS+LABA combination therapy in patients with a history of COPD and asthma was associated with lower composite risk of hospitalization or death compared with LABA treatment alone.
- A more recent study showed some efficacy with the use of omalizumab as an effective and safe therapy for patients with ACOS. However, this study included only three patients; therefore, larger randomized trials are needed.

CHRONIC Rx

- Earlier screening of the overlap syndrome is important in current or former smokers in their fifth decade of life who have partially reversible airway obstruction and progressive exercise intolerance and who have variable or no response to guideline-recommended asthma treatments. Smoking cessation, oxygen supplementation, pulmonary rehabilitation, and vaccines are all reasonable interventions.
- As the prevalence of overlap syndrome increases with age, targeting nonrespiratory age-related changes that may influence respiratory disease is paramount. This includes targeting nasal obstruction symptoms (due to nonallergic or allergic rhinitis, mucosal dryness, or vasomotor symptoms) with nasal irrigation, nasal steroids, and/or nasal anticholinergics.
- Treating comorbidities such as chronic aspiration, gastroesophageal reflux disease (GERD), or vocal cord dysfunction (VCD) is important.
- Evaluation for cardiovascular disease is important given the higher risk of cardiovascular disease in patients with asthma-COPD overlap syndrome even without the presence of comorbidities.

COMPLEMENTARY & ALTERNATIVE MEDICINE

None

REFERRAL

Referral for expert advice and further diagnostic evaluation is necessary in the following contexts:

- Persistent symptoms and/or exacerbations
- Diagnostic uncertainty
- Patients with asthma/COPD with atypical/additional symptoms such as hemoptysis, weight loss, night sweats, fevers, signs of bronchiectasis
- Comorbidities that may interfere with assessment and management
- No response to treatment

PEARLS & CONSIDERATIONS

PREVENTION

- Smoking cessation
- Avoidance of triggers

BASIC INFORMATION

DEFINITION

Astrocytoma is a type of neuroepithelial tumor that arises from astrocytes, which are glial precursor cells. The distinction of different grades of astrocytoma provides important clinical prognostic information (Table 1). According to the World Health Organization (WHO) classification astrocytoma is classified as below based on the histopathology:

- Grade I: Pilocytic astrocytoma
- Grade II: Diffuse astrocytoma
- Grade III: Anaplastic astrocytoma
- Grade IV: Glioblastoma
- Grades III and IV are considered high-grade astrocytomas (HGAs) or malignant

SYNONYM

Astroglial neoplasms

ICD-10CM CODE

C71.9 Malignant neoplasm of brain, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

According to Surveillance, Epidemiology, and End Results (SEER) registry, the incidence of primary CNS tumor is 6.4 cases per 100,000 persons per yr with age-adjusted death rate of 4.4 per 100,000. According to the Central Brain Tumor Registry of the United States (CBTRUS), astrocytomas constitute about 10% of the central nervous system neoplasms.

ETIOLOGY

- No agent has been definitely implicated in the causation of CNS tumors, and risk factors can be identified only in minority of patients. Farmers and petrochemical workers have been shown to have a higher incidence of primary brain tumors. Exposure to ionizing radiation is a known risk factor for a small percentage of astrocytomas.
- Different hereditary syndromes are associated with increased risk and high frequency of astrocytoma.
  1. Neurofibromatosis type 1 is associated with increased frequency of astrocytoma.
  2. Li-Fraumeni syndrome (germ line mutation in one of p53 allele) is associated with increased frequency of malignant gliomas.

GENE AND CHROMOSOMAL ALTERATIONS IN ASTROCYTOMA:

- Alteration in p53, a tumor suppressor encoded by the *TP53* gene on chromosome 17p, plays a key role in the development of at least one third of all grades of astrocytoma. In addition, in high-grade astrocytomas, p53 function may be deregulated by alteration of other genes, including amplification of MDM2 or MDM4 and 9p deletions that result in loss of the p14 product of the *CDKN2A* gene.
- Mutations of isocitrate dehydrogenase 1 gene (*IDH1*) occur in a large fraction of grade II and grade III astrocytomas as well as in other gliomas. IDH-mutated tumors have a better prognosis compared with those with IDH-wild type status.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The presenting symptoms of astrocytoma depend, in part, on the location of the lesion and its rate of growth. Astrocytomas classically present with any one or more of the following features:

- Headache (less frequent)
- New-onset partial or generalized seizures (>50%)
- Nausea and vomiting
- Focal neurologic deficit (cranial nerve palsy, hemiplegia, ataxia)
- Change in mental status
- Papilledema (rare)

DIAGNOSIS

A provisional diagnosis of astrocytoma is made on clinical grounds and radiographic imaging studies. Tissue pathology is needed to establish the diagnosis and to grade the astrocytoma.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis is vast and includes any cause of headache, seizures, change in mental status, and focal neurologic deficits.

WORKUP

- The imaging modality of choice is contrast-enhanced MRI, which can demonstrate anatomy and pathological process in detail. CT scanning is reserved for patients who are unable or unwilling to get MRI. Biopsy with histological confirmation is required to establish a diagnosis of astrocytoma.
- Stereotactic biopsy under CT or MRI guidance has been reserved for tumors that are deeply seated, multicentric tumors or diffuse nonfocal tumors where surgical resection is not practical. Major objectives of surgical resection are to maximally remove the tumor bulk, reduce tumor-associated mass effect and elevated intracranial pressure and provide tissue for pathological analysis. The surgical resection is carried out in a manner that minimizes the risk to neurological functioning. Surgery can also rapidly reduce the tumor bulk with potential benefits in terms of mass effect, edema, and hydrocephalus.

LABORATORY TESTS

There are no diagnostic or supportive blood tests for astrocytoma.

IMAGING STUDIES

MRI (Fig. 1) is the diagnostic imaging study of choice. MRI with contrast and magnetic resonance angiography are used to locate the margins of the tumor, distinguish vascular masses from tumors, detect low-grade astrocytomas (LGAs) not seen by CT scan, and provide clear views of the posterior fossa.

TREATMENT

ACUTE GENERAL Rx

- Corticosteroids (usually dexamethasone) need to be started immediately preoperatively in all primary CNS tumors unless CNS lymphoma is being suspected. Corticosteroids reduce cerebral edema and thus minimize secondary brain injury from cerebral retraction. Corticosteroids needs to be continued in the immediate postoperative period and tapered as quickly as possible. If there is increased intracranial pressure and impending herniation, patient should be started

TABLE 1 Comparison of Astrocytoma Histopathology

	Pilocytic Astrocytoma	Diffuse Astrocytoma	Anaplastic Astrocytoma	Glioblastoma Multiforme
Malignant potential	Benign	Low grade	High grade	Very malignant
Age (approximate)	Children	Third or fourth decade	Fifth decade	Sixth decade
Location	Optic chiasm or hypothalamus > cerebellum > brainstem*	Hemispheres (cortex + white matter)	Hemispheres (cortex + white matter)	Hemispheres (cortex + white matter)
Enhancement	Mild	Mild	Moderate (ring)	Intense
Vasogenic edema	Minimal	Minimal	Moderate	Significant
Calcification	Common	Up to 20%	Occasional	Rare

*It is typically cystic with a mural nodule and located within the posterior fossa—it tends to be solid or lobulated when seen elsewhere.
From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.

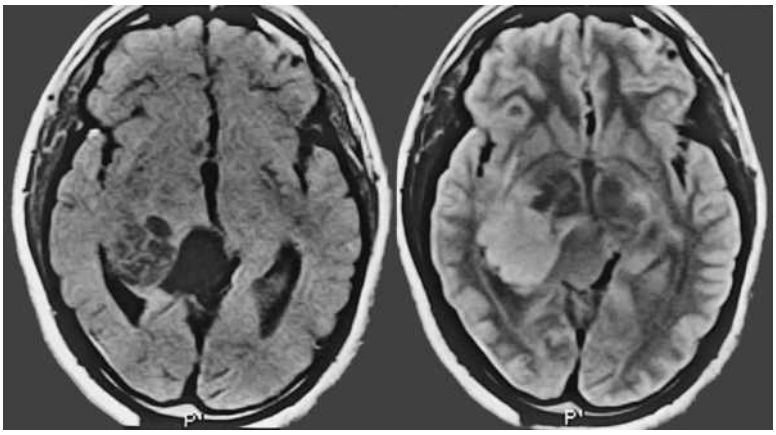

FIG. 1 Magnetic resonance image of a low-grade astrocytoma, demonstrating a hypointense right temporal lesion without contrast enhancement on T1 and hyperintense signal on T2. (From Goetz CG, Pappert EJ: *Textbook of clinical neurology,* Philadelphia, 1999, WB Saunders.)

on IV mannitol, and mechanical ventilation with hyperventilation should be considered if there is depressed consciousness.
- The use of preoperative prophylactic anticonvulsants is less commonly indicated. The practice pattern in the U.S. seems to indicate its widespread use.

STAGE-SPECIFIC Rx

- Grade I astrocytomas are usually indolent and circumscribed tumors. Complete surgical resection is the mainstay of therapy whenever feasible and is curative for these tumors. If complete surgical resection is not feasible due to location of tumor such as when the tumor is in optic pathway, hypothalamus, and in deep midline structures, asymptomatic patients can be observed in these cases until maximally safe resection is feasible upon progression. Unfortunately, despite aggressive near-total resection, delayed recurrence and eventual malignant transformation are common.
- In grade II astrocytoma, the extent of postoperative residual disease is an important variable for time to first relapse. Postoperative use of PCV chemotherapy (procarbazine, lomustine, and vincristine regimen) concurrent with radiotherapy improves progression-free survival and overall survival.
- In grade III anaplastic astrocytoma, surgical resection has shown to prolong survival and postoperative chemotherapy and radiotherapy is routinely used. Recent randomized clinical trials have established a survival benefit with the use of concurrent chemotherapy (temozolomide) for 6 to 12 mo.
- In grade IV glioblastoma, surgical resection improves median survival. Randomized trials have demonstrated survival benefit with use of concurrent chemotherapy with radiotherapy followed by further 6 mo of temozolomide chemotherapy alone. Unfortunately, even with chemotherapy and radiation therapy, the 2-yr survival in these patients is only 16%.

TREATMENT OF RECURRENT DISEASE

- For grade 1 astrocytoma, re-resection should be considered. For patients who have tumors that are not amenable to resection, chemotherapy or radiotherapy can improve recurrence-free survival, although role of chemotherapy in adults remain controversial.
- For grade 2 astrocytoma, radiation therapy can be considered in the relapsed setting if not given in the adjuvant setting. Data on use of chemotherapy in low-grade gliomas in adults is sparse. Although the results are encouraging, number of patients treated in these studies is small and there were a lot of methodological flaws in the studies. For recurrent grade III anaplastic astrocytoma treated with radiation therapy in the past, there is a role for chemotherapy. Nitrosoureas-based regimen and temozolomide (alkylating agent) have shown efficacy in this setting.
- Various targeted therapies are currently being studied in patients with recurrent glioblastoma. Irinotecan with bevacizumab or bevacizumab alone have been studied in a phase 2 trial, and a response rate of 38% and 28% respectively was reported in that study. Median survival was 8.7 mo and 9.2 mo, respectively. The PD-1 checkpoint inhibitors are currently being evaluated and have shown promising early results in relapsed patients.
- In the case of both recurrent and newly diagnosed glioblastoma, the use of tumor-treatment fields (TTF) devices in conjunction with the use of temozolomide chemotherapy has demonstrated a survival benefit and is approved by the FDA.

PROGNOSIS

- Grade 1 astrocytoma has a good prognosis and is usually cured with surgical resection.
- Grade 2 astrocytoma has a median survival of about 7.5 yr with treatment.
- Grade 3 anaplastic astrocytoma has a median survival of approximately 5 yr. The patients with 1p and 19q co-deletion have superior survival compared with patients without deletion.
- Median survival of glioblastoma is approximately 14 mo.

REFERRAL

A multidisciplinary consultation with a neurosurgeon, radiation oncologist, and neurooncologist is required to assist in the diagnostic workup and to provide immediate and follow-up treatment.

Ataxia

BASIC INFORMATION

DEFINITION

Although ataxia typically is used to describe an unbalanced, incoordinated gait, the term is commonly used more expansively to refer to a general incoordination of movement that can affect movements of the limbs, the trunk, the oropharyngeal apparatus used for swallowing and speaking, and eye movements. The most common presentation is a complaint of imbalance when walking, leading to falls or walking into walls. People with gait ataxia have a broad-based gait and have difficulty with tandem walking.

SYNONYMS

Gait instability
Loss of balance
Functional impairment

ICD-10CM CODES

R27.0	Ataxia, unspecified
G11.0	Congenital nonprogressive ataxia
G11.1	Early-onset cerebellar ataxia
G11.2	Late-onset cerebellar ataxia
G11.3	Cerebellar ataxia with defective DNA repair
G11.8	Other hereditary ataxias
G11.9	Hereditary ataxia, unspecified
G32.81	Cerebellar ataxia in diseases classified elsewhere
G60.2	Neuropathy in association with hereditary ataxia
I69.093	Ataxia following nontraumatic subarachnoid hemorrhage
I69.193	Ataxia following nontraumatic intracerebral hemorrhage
I69.293	Ataxia following other nontraumatic intracranial hemorrhage
I69.393	Ataxia following cerebral infarction
I69.893	Ataxia following other cerebrovascular disease
I69.993	Ataxia following unspecified cerebrovascular disease

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Hereditary ataxia can affect 1 in 50,000 people in the U.S.
PEAK INCIDENCE: Can affect all age groups. Hereditary ataxias peak in young adulthood. Ataxia after age 65 is commonly secondary to stroke.
PREVALENCE: 13.9 per 10,000
PREDOMINANT SEX AND AGE: Ataxia can affect both sexes in equal proportions.
GENETICS: The most common type of inherited ataxia in the U.S. is Friedreich ataxia (FA), which is autosomal recessive. The second most inherited ataxia is autosomal dominant spinocerebellar ataxia (SCA) type 3.
RISK FACTORS:

- A positive family history of ataxia
- Excessive alcohol use
- Hypothyroidism
- Chronic anticonvulsant use
- A history of celiac disease
- A history of cerebrovascular disease

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most individuals will complain of unsteadiness and eventually frequent falls. They may also experience double vision or a sense of the environment moving. Speech may become unintelligible, and they are frequently asked to repeat themselves. A history of difficulty cycling or performing physical activities may be present.
- Physical exam findings include slurred speech, nystagmus, square wave jerks, dysconjugate gaze, and ocular bobbing. Dysmetria and past pointing may be noted in the finger to nose and heel to shin testing. Dysdiadochokinesia may be noted on exam.
- Gait is notable for having a wide base and for difficulty turning with easy falling to one side. Frequent truncal swaying and veering is present. Tandem gait is abnormal.

ETIOLOGY

- Ataxia can be caused by a variety of diseases.
- Genetic causes of ataxia include Friedreich ataxia, the many spinocerebellar ataxias, ataxia telangiectasia, the episodic ataxias, ataxia with oculomotor apraxia, abetalipoproteinemia, and diseases such as MELAS (mitochondrial encephalopathy, lactic acidosis, stroke-like episodes) or MIRAS (mitochondrial recessive ataxic syndrome).
- Strokes of the cerebellum or of the cerebellar inflow or outflow tracks.
- Infections of the cerebellum such as cerebellar brain abscesses or meningitis involving the cerebellar meninges.
- Tumors of the cerebellum, as well as carcinomatosis and lymphomatosis.
- Arnold-Chiari malformation.
- Metabolic causes include hypothyroidism, chronic alcohol use, chronic phenytoin use, and deficiencies of vitamin E, B_1, and B_{12}.
- Immune causes include multiple sclerosis, postinfectious cerebellitis, gluten ataxia due to celiac disease, Hashimoto encephalopathy, Miller Fisher variant of Guillain-Barré syndrome, anti-GAD65 associated cerebellar ataxia, and paraneoplastic syndromes, most commonly subacute cerebellar degeneration associated with anti-Yo antibodies due to breast, ovarian, or uterine malignancies, but also including other paraneoplastic syndromes that can manifest with cerebellar ataxia, such as anti-Hu associated with small cell lung cancer.
- Genetic disorders such as Friedreich ataxia (autosomal recessive) or the many numbered spinocerebellar ataxias (autosomal dominant)
- Severe large-fiber neuropathy
- Ganglionopathy
- Epilepsy
- Celiac disease
- Wilson disease
- Cerebral anoxia
- Cerebellar tumors
- Stroke
- Postinfectious cerebellitis
- Miller-Fisher variant of Guillain-Barré syndrome
- Paraneoplastic subacute cerebellar degeneration
- Anti-GAD65-associated cerebellar ataxia
- Leptomeningeal diseases affecting the cerebellum
- Conversion disorder

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vitamin deficiency: B_1 (thiamine), B_6 (pyridoxine), B_{12} (cobalamin), copper
- Vitamin excess: B_6 (pyridoxine)
- Alcoholism
- Anticonvulsant use, such as phenytoin

WORKUP

- The workup for ataxia should be systematic and should always look for easily reversible disorders.
- Always start with a family history and investigate for any family members that were affected. This may guide genetic testing.
- Acute-onset ataxia warrants consideration of an acute stroke with appropriate brain imaging.
- Brain imaging, preferably magnetic resonance imaging (MRI), is highly recommended.
- A lumbar puncture may be necessary if infectious, immune-mediated, or neoplastic leptomeningeal disease is suspected.
- If a malignancy is present, then consider an appropriate paraneoplastic panel. However, the paraneoplastic syndrome may precede the appearance of a malignancy on imaging, and a paraneoplastic panel for cerebellar degeneration may be appropriate once other more common etiologies have been ruled out.

LABORATORY TESTS

- Complete metabolic panel, including liver function tests
- Complete blood count with differential and peripheral smear
- Thyroid function tests
- HIV and RPR
- Vitamin B_{12} and vitamin E
- Anti-tissue transglutaminase
- Serum copper and ceruloplasmin
- In selected cases: Genetic testing for spinocerebellar ataxias, paraneoplastic panel for cerebellar degeneration, anti-GAD65 antibodies, anti-TPO antibodies, and lumbar puncture for cytology if leptomeningeal carcinomatosis or lymphomatosis is suspected
- Notes about laboratory testing:
  1. Thiamine levels are not reliable for detecting thiamine deficiency. Thiamine pyrophosphate or erythrocyte transketolase activation may be better, but neither the sensitivity nor specificity of these tests has been established.

2. Total cholesterol must be measured concomitantly with vitamin E levels to interpret result of vitamin assay.
3. Low normal vitamin B_{12} levels of up to 400 pg/ml range can still result in neurological dysfunction. Measuring methylmalonic acid and homocysteine levels is more sensitive in patients with low normal vitamin B_{12} levels, with a high level suggesting vitamin B_{12} deficiency.
4. Electromyography and nerve conduction studies are warranted when the ataxia is thought to be due to peripheral nerve demyelination or part of a myeloneuropathy causing both peripheral neuropathy and dorsal column dysfunction, leading to proprioceptive loss from a sensory ataxia.

IMAGING STUDIES

- MRI of the brain with and without contrast is preferable.
- Computed tomography (CT) scan of the head if MRI is not feasible.
- Cardiac echocardiogram is recommended for the inherited ataxias.

Rx TREATMENT

Treatment of ataxia is highly variable. The best way to treat ataxia is to investigate the cause and, if treatable, then treat the underlying condition. For example, if there is a vitamin deficiency, then vitamin replacement is recommended. Table E1 summarizes treatable causes of inherited ataxia.

However, sometimes the cause is genetic or unknown, and treatment is directed at minimizing complications, such as neuropathy or cardiac disease, and rehabilitative therapy for the ataxia and motor complications.

NONPHARMACOLOGIC THERAPY

Rehabilitative services such as physical, occupational, and speech therapy are a necessary part of the treatment of all ataxias, and evidence suggests it does improve functional status for individuals affected by ataxia.

ACUTE GENERAL Rx

Abrupt and sudden ataxia should always be worked up for stroke, which includes following an established acute stroke protocol.

CHRONIC Rx

Search for the underlying cause and focus on symptomatic management to prevent future disabilities. Rehabilitative services are integral to long-term care. Always evaluate cardiac and renal function and check for signs of developing neuropathy.

COMPLEMENTARY & ALTERNATIVE MEDICINE

There are currently no widely accepted or evidence-based forms of complementary medicine for ataxia.

DISPOSITION

Reversible causes of ataxia may see rapid improvement in symptoms. Genetic ataxias tend to be progressive.

REFERRAL

Always refer to a neurologist.

PEARLS & CONSIDERATIONS

COMMENTS

Look for reversible causes.

PREVENTION

A gluten-free diet would be preferable for people with celiac sprue disease.

PATIENT & FAMILY EDUCATION

Educate families on the need to be supportive and make the home environment safe.

TABLE E1 Treatable Causes of Inherited Ataxia

Disorder	Metabolic Abnormality	Distinguishing Clinical Features	Treatment
Acute disseminated encephalomyelitis	Demyelination	Positive MRI findings	Steroids, IVIG, rituximab
Ataxia with vitamin E deficiency	Mutation in α-tocopherol transfer protein	Ataxia, areflexia, retinopathy	Vitamin E
Bassen-Kornzweig syndrome	Abetalipoproteinemia	Acanthocytosis, retinitis pigmentosa, fat malabsorption	Vitamin E
Hartnup disease	Tryptophan malabsorption	Pellagra rash, intermittent ataxia	Niacin
Familial episodic ataxia type 1 and type 2	Mutations in potassium channel (KCNA1) and α_{1A} voltage-gated calcium channel, respectively	Episodic attacks, worse with pregnancy or birth control pills	Acetazolamide
Multiple carboxylase deficiency	Biotinidase deficiency	Alopecia, recurrent infections, variable organic aciduria	Biotin
Mitochondrial complex defects	Complexes I, III, IV	Encephalomyelopathy	Possibly riboflavin, CoQ10, dichloroacetate
Opsoclonus-myoclonus-ataxia syndrome	Paraneoplastic or spontaneous autoimmune	Underlying neuroblastoma or autoantibodies	Steroids, IVIG, rituximab
Pyruvate dehydrogenase deficiency	Block in E-M and Krebs cycle interface	Lactic acidosis, ataxia	Ketogenic diet, possibly dichloroacetate
Refsum disease	Phytanic acid, α-hydroxylase	Retinitis pigmentosa, cardiomyopathy, hypertrophic neuropathy, ichthyosis	Dietary restriction of phytanic acid
Urea cycle defects	Urea cycle enzymes	Hyperammonemia	Protein restriction, arginine, benzoate, α-ketoacids

CoQ10, Coenzyme Q10; *E-M,* mitochondrial electron transport; *IVIG,* intravenous immunoglobulin.

BASIC INFORMATION

DEFINITION

Ataxia telangiectasia (AT) is a rare autosomal recessive disorder of childhood that results from defective DNA repair mechanisms. AT is a multisystem disease characterized by progressive cerebellar ataxia, choreoathetosis, oculocutaneous telangiectasias (Fig. E1), frequent infections, increased sensitivity to ionizing radiation, and predisposition to malignancies.

ICD-10CM CODE

G11.3 Cerebellar ataxia with defective DNA repair

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 1/40,000 live births; it is estimated that 1.4% to 2% of whites in the U.S. carry one defective AT gene. It is the second most common cause of autosomal recessive ataxia after Friedreich ataxia.

PEAK INCIDENCE: Childhood (onset at age 1 to 5 yr)

PREDOMINANT SEX: Males and females are equally affected.

GENETICS: Condition is autosomal recessive and progressive. The defective gene, designated *ATM* (for AT mutated), has been mapped to chromosome 11q22-23. More than 100 mutations have been discovered. The gene product, expressed in all tissues, encodes a large nuclear and cytoplasmic protein kinase that is a member of the phosphatidylinositol-3 kinases and another region similar to DNA repair genes. It becomes recruited and activated by double-stranded DNA breaks and phosphorylates several downstream proteins, which lead to cell cycle arrest, DNA repair, or apoptosis. Developing lymphocytes also require the *ATM* gene product for V(D)J recombination, an essential step in the diversification of lymphocyte antigen receptors.

FIG. E1 Ataxia telangiectasia. (From Callen JP [ed]: *Color atlas of dermatology,* ed 2, Philadelphia, 2000, Saunders.)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Children show normal early development until they start to walk, when gait and truncal ataxia become apparent. Thereafter, children develop polyneuropathy, progressive apraxia of eye movements, slurred speech, choreoathetosis, mild diabetes mellitus, delayed physical and sexual development, and signs of premature aging (graying of the hair, loss of skin elasticity and subcutaneous fat).
- Progression, at times, may be so indolent that the condition is misdiagnosed as cerebral palsy.
- Children with AT experience deterioration of motor skills. By the second decade of life, most patients rely on wheelchairs for at least part of the day. Progressive oromotor difficulties also develop over time, placing patients at risk for aspiration.
- Typically, individuals with AT initially have normal intelligence that deteriorates over time until it plateaus at approximately 10 yr of age. As deterioration of motor skills occurs much more aggressively, scholastic skills can become impeded, leading to inaccurate results on traditional timed neuropsychological assessments. Deterioration of speech is typically noted after 5 to 8 yr of age.
- Telangiectasias are virtually pathognomonic for AT and can aid in diagnosis, but they typically appear after 6 yr of age. Sometimes either a complete absence of telangiectasias or a delay in the appearance of telangiectasias results in a delayed diagnosis. Telangiectasias occur primarily in the bulbar conjunctivae and have been misdiagnosed as conjunctivitis. The telangiectasias can progress over the surface of the ears and cheeks, in the corners of the eyes, on exposed parts of the neck, on the bridge of the nose, and in the flexor creases of the forearms. Children with AT may also have café-au-lait macules, hypopigmented macules, or melanocytic nevi.
- Immunodeficiencies occur in 60% to 80% of individuals with AT due to B-cell and T-helper cellular dysfunction and defective V(D)J recombination, leading to abnormal immunoglobulin subclasses. Serum and saliva IgA is absent in 70% to 80%. Serum IgE is low or absent in 80% to 90%, and serum IgM may be elevated. Thymic and other lymphoid tissue frequently have hypoplastic and embryonic appearance. Impaired humoral and cellular immunities lead to recurrent sinopulmonary infections. The severity of immunodeficiency is unrelated to the severity of neurologic phenotype and is also not progressive. Recurrent sinopulmonary infections and aspirations, however, can lead to bronchiectasis later in life.
- In the central nervous system, there is loss of Purkinje cells in the cerebellum, and surviving Purkinje cells may contain eosinophilic cytoplasmic inclusions. Older individuals experience demyelination of the posterior columns and dorsal spinocerebellar tracts. There are also reports of anterior horn cell loss. Peripheral nerves can develop lipid inclusions in Schwann cells, resulting in secondary axonal degeneration.
- Malignancy: Beyond 10 yr of age, the incidence rate is 1% per yr; the overall risk rate is approximately 30% to 40%, of which 85% of cases are leukemia and lymphoma. Predisposition to other cancers (e.g., breast cancer) may also exist, thought to be caused by the phosphorylation of the tumor-suppressor/breast cancer susceptibility gene *BRCA1* by *ATM*.
- Up to 2% of the U.S. population may be carriers of AT. Heterozygote/carriers of the *ATM* gene are thought to have none of the classic manifestations of AT; however, they may have a greater incidence of malignancy at a younger age.

ETIOLOGY

- Cytogenetics show a 7;14 translocation in 5% to 15% of individuals with AT. Cloning and sequencing has identified the ATM (Ataxia Telangiectasia, Mutated, Mapped to chromosome 11q22.3) gene, a protein kinase that is either missing or defective. The ATM mutation delays accumulation of the tumor-suppressor p53 in response to DNA damage, thereby increasing cancer risk. Cells are susceptible to damage by both ionizing radiation and chemotherapeutic agents that cause double-stranded DNA breakages (also see "Genetics" section of this topic).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Early-onset ataxia:

- Friedreich ataxia
- Abetalipoproteinemia (Bassen-Kornzweig syndrome)
- Acquired vitamin E deficiency
- Early-onset cerebellar ataxia with retained reflexes (EOCA)
- Ataxia-ocular apraxia type 1 (AOA1)
- Ataxia-ocular apraxia type 2 (AOA2)
- Ataxia telangiectasia-like disorder (ATLD)
- Spinocerebellar ataxia
- Juvenile GM2 gangliosidosis
- Juvenile sulfatide lipidosis
- Marinesco-Sjögren syndrome
- Hartnup disease and maple syrup urine disease
- Infantile adrenoleukodystrophy (X-linked)

WORKUP

Diagnosis relies on the constellation of clinical findings, including ataxia and speech changes, as well as family history and neuroimaging studies.

LABORATORY TESTS

- Acanthocytes are frequently seen on smear.
- Serum immunoglobulin levels (IgA, IgG, IgE, and IgG subclasses) should be measured to evaluate for immunoglobulin deficiency and oligoclonal gammopathy.

- Serum α-fetoprotein is increased in more than 95% of patients with AT older than the age of 8 mo.
- Prenatal testing is available. Fibroblasts can be screened for abnormal sensitivity to ionizing radiation.
- Immunoblotting is the most sensitive and specific way to detect the ATM protein. Approximately 90% of individuals have no detectable ATM protein.

IMAGING STUDIES

CT or MRI scans will show cerebellar atrophy in nearly all children with ATM between 2 and 8 yr of age. Telangiectasias may be observed as punctate hemosiderin deposits.

Rx TREATMENT

- No proven disease-specific treatment is currently available. Treatment is focused on amelioration of disease manifestations.
- Surveillance for infections and neoplasms is necessary. Individuals with frequent and severe infections may benefit from intravenous immunoglobulin. Some have been placed on prophylactic antibiotics. Children should be immunized with pneumococcal and influenza vaccines.
- The cloning and sequencing of the gene for AT have opened several avenues for intervention, including gene therapy, targeted pharmacologic intervention to correct the function of the altered protein, and direct replacement of the functional protein.
- Recent studies suggest symptomatic improvement with glucocorticoids, which are postulated to induce alternative splicing of the ATM protein and result in retained protein kinase activity.

NONPHARMACOLOGIC THERAPY

- Minimize radiation because it may induce further chromosomal damage and lead to neoplasms. Even diagnostic radiographs should be limited because of the theoretical risk that radiation may lead to chromosomal breakages.
- Monitor swallowing as needed to evaluate for aspiration.
- Physical and occupational therapy to maintain flexibility and minimize contractures.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Antioxidant treatment with vitamin E is often given empirically, though it has not been formally tested. α-Lipoic acid crosses the blood-brain barrier and may therefore have some advantage.

DISPOSITION

AT has a poor prognosis given the multisystem involvement; however, the expected life span has increased considerably. Most individuals now live beyond 25 yr of age and some into the fourth and fifth decades of life. Morbidity is typically related to either infection or neoplasm.

REFERRAL

- Immunology
- Neurology
- Gastroenterology and nutrition
- Physical and occupational therapy
- Genetic counselor

PEARLS & CONSIDERATIONS

COMMENTS

- Most common cause of hereditary ataxia
- Defect in DNA repair
- Predisposition to frequent infections, malignancies, and sensitivity to ionizing radiation

National Ataxia Foundation (NAF): www.ataxia.org

RELATED CONTENT

Ataxia (Related Key Topic)

AUTHORS: **Chloe Mander Nunneley, MD, Joseph S. Kass, MD, JD, FAAN,** and **Nicole J. Ullrich, MD, PhD**

BASIC INFORMATION

DEFINITION

Atelectasis describes collapse of lung with some degree of volume loss. There are two major types of atelectasis. Obstructive atelectasis is the most common type due to reabsorption of gas from alveoli when communication between alveoli and the trachea is obstructed. Nonobstructive atelectasis is usually due to loss of contact between parietal and visceral pleura, compression (pleural effusion), or loss of surfactant.

ICD-10CM CODE
J98.11 Atelectasis

EPIDEMIOLOGY & DEMOGRAPHICS

- Postoperative patients and patients with lung or chest wall injury are at increased risk of atelectasis.
- Asbestos exposure increases risk for an entity called "rounded atelectasis."
- Occurs frequently in patients receiving mechanical ventilation.
- There is no known racial or sexual predilection for atelectasis.
- Dependent regions of the lung are more prone to atelectasis.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Decreased or absent breath sounds
- Abnormal chest percussion
- Cough, dyspnea, decreased vocal fremitus, and vocal resonance
- Diminished chest expansion, tachypnea, tachycardia

ETIOLOGY

- Trauma caused by shear force generated by repetitive expansion and collapse during positive-pressure ventilation (e.g., mechanical ventilation)
- Airway obstruction (e.g., endobronchial tumor, a lymph node, foreign bodies, mucus plug)
- Extrinsic bronchial compression (e.g., neoplasms, aneurysms of ascending aorta, enlarged left atrium)
- Pleural disease (e.g., pleural effusion, mesothelioma, rounded atelectasis, pneumothorax)
- Alveolar injury (e.g., toxic fumes, aspiration of gastric contents, infections, acute respiratory distress syndrome)
- Chest wall abnormalities (e.g., trauma, scoliosis, rib fracture, obesity)
- Impaired respiratory mechanics or decreased cough response (e.g., pain, postanesthetic effect, abdominal distention, neuromuscular disease)
- Table 1 summarizes anatomic causes of atelectasis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Neoplasm (Bronchogenic carcinoma must be excluded)
- Pneumonia
- Pleural effusion
- Abnormalities of brachiocephalic vein and the left pulmonary ligament

WORKUP

- Chest x-ray (Fig. 1)
- Thoracic ultrasonography
- CT scan (Prone positioning CT scan with improvement or reduction in atelectasis may be used to differentiate from other etiology)
- Fiberoptic bronchoscopy (selected patients)

IMAGING STUDIES

- Chest radiograph suggests the diagnosis but fails to confirm the diagnosis in many cases.
- Ultrasonography helps differentiate atelectasis from effusion or consolidation.
- CT scan is useful in patients with suspected endobronchial neoplasm or extrinsic bronchial compression.
- Prone images help differentiate true consolidation from dependent atelectasis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Deep breathing, mobilization of the patient
- Incentive spirometry
- Handheld positive end-expiratory pressure (PEEP) devices (e.g., PEEP valve, Acapella)
- Tracheal suctioning in select patients (e.g., mechanical ventilation and tracheostomy)
- Humidification
- Therapies for improving cough and clearance of secretions from airways (chest physiotherapy, chest wall percussion, and postural drainage)
- Fiberoptic bronchoscopy (selected patients) might be helpful with mucous plug, removal of foreign body, or evaluation of endobronchial and peribronchial lesions

ACUTE GENERAL Rx

- Positive-pressure breathing (continuous positive airway pressure by face mask, positive end-expiratory pressure for patients on mechanical ventilation)
- Use of mucolytic agents (e.g., acetylcysteine [Mucomyst])
- Recombinant human DNase (dornase alpha) in patients with cystic fibrosis
- Bronchodilator therapy in selected patients
- Pain control in postoperative and trauma cases
- Pleural drainages in cases of large effusions, hemothorax, or empyema
- Treatment of atelectasis is summarized in Table 2

CHRONIC Rx

- Chest physiotherapy
- Humidification of inspired air
- Frequent nasotracheal suctioning

DISPOSITION

Prognosis varies with the underlying etiology

REFERRAL

- Bronchoscopy for removal of foreign body or plugs unresponsive to conservative treatment
- Surgical referral for removal of obstructing neoplasm

PEARLS & CONSIDERATIONS

COMMENTS

Patients should be educated that frequent changes of position are helpful in clearing secretions. Sitting the patient upright in a chair is recommended to increase both volume and vital capacity relative to the supine position. Adequate pain control is paramount after surgical intervention or rib fractures.

RELATED CONTENT

Atelectasis (Patient Information)

AUTHORS: **Harinder P. Singh, MD,** and **Samaan Rafeq, MD**

TABLE 1 Anatomic Causes of Atelectasis

Cause	Clinical Examples
External compression on the pulmonary parenchyma	Pleural effusion, pneumothorax, intrathoracic tumors, diaphragmatic hernia
Endobronchial obstruction completely obstructing the ingress of air	Enlarged lymph node, tumor, cardiac enlargement, foreign body, mucoid plug, broncholithiasis
Intraluminal obstruction of a bronchus	Foreign body, asthma, granulomatous tissue, tumor, secretions including mucous plugs, bronchiectasis, pulmonary abscess, chronic bronchitis, acute laryngotracheobronchitis, plastic bronchitis
Intrabronchiolar obstruction	Bronchiolitis, interstitial pneumonitis, asthma
Respiratory compromise or paralysis	Neuromuscular abnormalities, osseous deformities, overly restrictive casts and surgical dressings, defective movement of the diaphragm, or restriction of respiratory effort

From Kliegman RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.

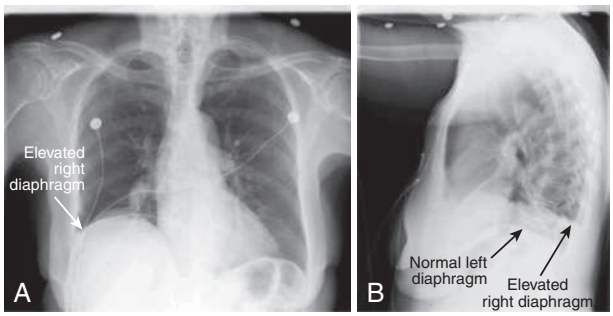

FIG. 1 Atelectasis with elevated diaphragm: An example of volume loss. The right hemidiaphragm in this patient appears elevated on both the posterior-anterior **(A)** and the lateral **(B)** views. Is this the correct interpretation of the x-ray, and if so, what is the cause? Consider the alternative interpretations. A subpulmonic pleural effusion would appear similar, as it would have the same density as liver, heart, and diaphragm and would layer over the diaphragm with the patient upright. This appears less likely in that a meniscus might be seen along the lateral chest wall with a pleural effusion but is not present here. In addition, a pleural effusion occupies space and might be expected to push the heart to the left, whereas in this case the heart may be slightly deviated to the right. Atelectasis of the lower right lung would result in volume loss, pulling the heart and hemidiaphragm into the space normally occupied by lung. This is consistent with the observed features. An infiltrate in this location could explain the x-ray findings but appears less likely for similar reasons to those cited for effusion. Some simple maneuvers could narrow the differential diagnosis. Chest ultrasound, decubitus x-ray views, or CT could identify an effusion. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.)

TABLE 2 Treatment for Atelectasis

Cause of Atelectasis	Treatment
Pleural effusion or pneumothorax	Relieve compression
Mucus plug	Tracheal or bronchoscopic aspiration Continuous positive airway pressure
Foreign body	Bronchoscopic examination
Asthma	Bronchodilator and corticosteroid treatment Recombinant human deoxyribonuclease (off label use) Hypertonic saline with or without bronchodilator
Neuromuscular diseases	Intermittent positive pressure breathing Mechanical insufflator–exsufflator Noninvasive bilevel positive pressure ventilation
Cystic fibrosis	Airway clearance therapies Hypertonic saline with or without bronchodilator

From Kliegman RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.

Atopic Dermatitis PTG

BASIC INFORMATION

DEFINITION

Atopic dermatitis is a genetically determined eczematous eruption that is pruritic, symmetric, and associated with personal family history of allergic manifestations (atopy). Box 1 summarizes criteria for atopic dermatitis. Modified criteria for children with atopic dermatitis are described in Box 2.

SYNONYMS

Eczema
Atopic neurodermatitis
Atopic eczema

ICD-10CM CODES	
L20.9	Atopic dermatitis, unspecified
L20.89	Other atopic dermatitis

EPIDEMIOLOGY & DEMOGRAPHICS

- Incidence is between 5 and 25 cases/1000 persons.
- Highest incidence is among children (10% to 20%). It accounts for 4% of acute care pediatric visits. It affects 1% to 3% of the adult population.
- Onset of disease before age 5 yr in 85% of patients.
- More than 50% of children with generalized atopic dermatitis develop asthma and allergic rhinitis by age 13 yr.
- Concordance in monozygotic twins is 77%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Atopic dermatitis presentation can be subdivided into three phases:
  1. Acute: Vesicular, crusting, weeping eruption.
  2. Subacute: Dry, scaly, erythematous papules and plaques.
  3. Chronic: Lichenification from repeated scratching.
- The lesions are typically on the neck, face, upper trunk, and bends of elbows and knees (symmetric on flexural surfaces of extremities) (Fig. 1, *A*, and Fig. E2). Atopic dermatitis lesions are usually discrete but vaguely delineated, scaly, and erythematous.
- There is dryness, thickening of the involved areas, discoloration, blistering, and oozing.
- Papular lesions are frequently found in the antecubital and popliteal fossae.
- In children, red scaling plaques are often confined to the cheeks and the perioral and perinasal areas.
- ***Hertoghe sign:*** Loss of the outer eyebrow from chronic rubbing (Fig. 1, *B*).
- Constant scratching may result in areas of hypopigmentation or hyperpigmentation (more common in blacks).
- In adults, redness and scaling in the dorsal aspect of the hands or about the fingers are the most common expression of atopic dermatitis; oozing and crusting may be present.
- Secondary skin infections may be present (*Staphylococcus aureus,* dermatophytosis, herpes simplex).

ETIOLOGY

Unknown; elevated T-lymphocyte activation, defective cell immunity, and B-cell IgE overproduction may play a significant role.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Scabies
- Psoriasis
- Dermatitis herpetiform
- Contact dermatitis
- Photosensitivity
- Seborrheic dermatitis
- Candidiasis, tinea
- Lichen simplex chronicus
- Other: Xerosis, impetigo, Wiskott-Aldrich syndrome, phenylketonuria, ichthyosis, HIV dermatitis, nonnummular eczema, histiocytosis X, malignancies (T-cell lymphoma/mycosis fungoides, Letterer-Siwe disease), graft-versus-host disease, metabolic and nutritional deficiencies (zinc, niacin, pyridoxine deficiencies)

BOX 1 Criteria for Atopic Dermatitis

Major criteria
Must have three of the following:
- Pruritus
- Typical morphology and distribution
  - Flexural lichenification in adults
  - Facial and extensor involvement in infancy
- Chronic or chronically relapsing dermatitis
- Personal or family history of atopic disease (e.g., asthma, allergic rhinitis, atopic dermatitis)

Minor criteria
Must also have three of the following:
- Xerosis
- Ichthyosis or hyperlinear palms or keratosis pilaris
- IgE reactivity (immediate skin test reactivity, RAST test positive)
- Elevated serum IgE
- Early age of onset
- Tendency for cutaneous infections (especially *Staphylococcus aureus* and HSV)
- Tendency to nonspecific hand/foot dermatitis
- Nipple eczema
- Cheilitis
- Recurrent conjunctivitis
- Dennie-Morgan infraorbital fold
- Keratoconus
- Anterior subcapsular cataracts
- Orbital darkening
- Facial pallor or facial erythema
- Pityriasis alba
- Itch when sweating
- Intolerance to wool and lipid solvents
- Perifollicular accentuation
- Food hypersensitivity
- Course influenced by environmental or emotional factors
- White dermatographism or delayed blanch to cholinergic agents

HSV, Herpes simplex virus; *IgE,* immunoglobulin E; *RAST,* radioallergosorbent assay.
From James WD et al: *Andrews' diseases of the skin*, ed 12, Philadelphia, 2016, Saunders.

BOX 2 Modified Criteria for Children with Atopic Dermatitis

Essential features
- Pruritus
- Eczema
  - Typical morphology and age-specific pattern
  - Chronic or relapsing history

Important features
- Early age at onset
- Atopy
- Personal or family history
- IgE reactivity
- Xerosis

Associated features
- Atypical vascular responses (e.g., facial pallor, white dermatographism)
- Keratosis pilaris, ichthyosis, or hyperlinear palms
- Orbital or periorbital changes
- Other regional findings (e.g., perioral changes, periauricular lesions)
- Perifollicular accentuation, lichenification, or prurigo lesions

IgE, Immunoglobulin E.
From James WD et al: *Andrews' diseases of the skin*, ed 12, Philadelphia, 2016, Saunders.

FIG. 1 A, Flexural atopic dermatitis with lichenification. Many of the skin changes are secondary to scratching. Linear lichenification, as shown here, and excoriations are typical. **B,** Hertoghe sign: Loss of the outer eyebrow may occur in the atopic patient as a result of chronic rubbing. (From White GM, Cox NH [eds]: *Diseases of the skin, a color atlas and text,* ed 2, St Louis, 2006, Mosby.)

- Table 1 summarizes characteristics and clinical features of disorders in the differential diagnosis of atopic dermatitis

WORKUP

Diagnosis is based on the presence of three of the following major features and three minor features.

MAJOR FEATURES:

- Pruritus
- Personal or family history of atopy: Asthma, allergic rhinitis, atopic dermatitis
- Facial and extensor involvement in infants and children
- Flexural lichenification in adults

MINOR FEATURES:

- Elevated IgE
- Eczema-perifollicular accentuation
- Recurrent conjunctivitis
- Ichthyosis
- Nipple dermatitis
- Wool intolerance
- Cutaneous S. *aureus* infections or herpes simplex infections
- Food intolerance
- Hand dermatitis (nonallergic irritant)
- Facial pallor, facial erythema
- Cheilitis
- White dermographism
- Early age of onset (after 2 mo of age)

LABORATORY TESTS

- Lab tests are generally not helpful.
- Elevated IgE levels are found in 80% to 90% of atopic dermatitis.
- Consider skin biopsy only in cases unresponsive to treatment.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Clip nails to decrease abrasion of skin
- Avoidance of triggering factors:
  1. Sudden temperature changes, sweating, low humidity in the winter
  2. Contact with irritating substance (e.g., wool, cosmetics, some soaps and detergents, tobacco)
  3. Foods that provoke exacerbations (e.g., eggs, peanuts, fish, soy, wheat, milk)
  4. Stressful situations
  5. Allergens and dust
  6. Excessive hand washing
- Phototherapy in moderation may be effective in resistant cases

ACUTE GENERAL Rx

- Emollients can be used to prevent dryness. Severely affected skin can be optimally hydrated by occlusion in addition to application of emollients.
- Low-potency topical corticosteroids (e.g., 1% to 2.5% hydrocortisone) may be helpful and are generally considered first-line therapy. Use intermediate-potency steroids (e.g., triamcinolone, fluocinolone) for more severe cases and limit potent corticosteroids (e.g., betamethasone, desoximetasone, clobetasol) to severe cases. Table 2 summarizes relative potencies of topical corticosteroids.
- Crisaborole 2% ointment is a phosphodiesterase type-4 (PDE4) inhibitor modestly effective for short-term treatment of mild to moderate atopic dermatitis.
- Oral antihistamines (e.g., hydroxyzine, diphenhydramine) are effective in controlling pruritus and inducing sedation, restful sleep, and prevention of scratching during sleep. Doxepin and other tricyclic antidepressants also have antihistamine effect, induce sleep, and reduce pruritus.
- The topical immunomodulators pimecrolimus and tacrolimus are especially useful for treatment of the face and intertriginous sites, where steroid-induced atrophy may occur. However, due to concerns about carcinogenic potential, the FDA recommends limiting their use for short periods in patients who are intolerant or unresponsive to other treatments. Pimecrolimus cream 1% is applied bid and has antiinflammatory effects secondary to blockage of activated T-cell cytokine production. Tacrolimus ointment (0.03% or 0.1%) applied bid is a macrolide that suppresses humoral and cell-mediated immune responses.
- Oral prednisone, intramuscular triamcinolone, Goeckerman regimen, psoralen and ultraviolet A light therapy are generally reserved for severe cases.
- Cyclosporine, azathioprine, mycophenolate, and interferon gamma are sometimes tried for recalcitrant disease in adults by physicians who specialize in severe inflammatory skin conditions.
- The human monoclonal antibody dupilumab is effective in adults with moderate to severe atopic dermatitis that have not responded to topical therapies. It can be used with or without corticosteroids. It is injected subcutaneously. Cost is a limiting factor.
- Table 3 summarizes the management of atopic dermatitis.

DISPOSITION

- Resolution occurs in approximately 70% of patients by adulthood.
- Most patients have a course characterized by remissions and intermittent flares.

TABLE 1 Differential Diagnosis of Atopic Dermatitis (AD)

	Main Age Group Affected	Frequency*	Characteristics and Clinical Features
Other Types of Dermatitis			
Seborrheic dermatitis	Infants	Common	Salmon-red greasy scaly lesions, often on the scalp (cradle cap) and napkin area; generally presents in the first 6 wk of life; typically clears within weeks
Seborrheic dermatitis	Adults	Common	Erythematous patches with yellow, white, or grayish scales in seborrheic areas, particularly the scalp, central face, and anterior chest
Nummular dermatitis	Children and adults	Common	Coin-shaped scaly patches, mostly on legs and buttocks; usually no itch
Irritant contact dermatitis	Children and adults	Common	Acute to chronic eczematous lesions, mostly confined to the site of exposure; history of locally applied irritants is a risk factor; might coexist with AD
Allergic contact dermatitis	Children and adults	Common	Eczematous rash with maximum expression at sites of direct exposure but might spread; history of locally applied irritants is a risk factor; might coexist with AD
Lichen simplex chronicus	Adults	Uncommon	One or more localized, circumscribed, lichenified plaques that result from repetitive scratching or rubbing because of intense itch
Asteatotic eczema	Adults	Common	Scaly, fissured patches of dermatitis overlying dry skin, most often on lower legs
Infectious Skin Diseases			
Dermatophyte infection	Children and adults	Common	One or more demarcated scaly plaques with central clearing and slightly raised reddened edge; variable itch
Impetigo	Children	Common	Demarcated erythematous patches with blisters or honey-yellow crusting
Scabies	Children	Common†	Itchy superficial burrows and pustules on palms and soles, between fingers, and on genitalia; might produce secondary eczematous changes
HIV	Children and adults	Uncommon	Seborrhea-like rash
Keratinization Disorders			
Ichthyosis vulgaris	Infants and adults	Uncommon	Dry skin with fine scaling, particularly on the lower abdomen and extensor areas; perifollicular skin roughening; palmar hyperlinearity; full form (i.e., 2 *FLG* mutations) is uncommon; often coexists with AD
Nutritional Deficiency–Metabolic Disorders			
Zinc deficiency (acroder-matitis lenteropathica)	Children	Uncommon	Erythematous scaly patches and plaques, most often around the mouth and anus; rare congenital form accompanied by diarrhea and alopecia
Biotin deficiency (nutritional or biotinidase deficiency)	Infants	Uncommon	Scaly periorofacial dermatitis, alopecia, conjunctivitis, lethargy, hypotonia
Pellagra (niacin deficiency)	All ages	Uncommon	Scaly crusted epidermis, desquamation, sun-exposed areas, diarrhea
Kwashiorkor	Infants and children	Geographic dependent	Flaky scaly dermatitis, swollen limbs with cracked peeling patches
Phenylketonuria	Infants	Uncommon	Eczematous rash, hypopigmentation, blonde hair, developmental delay
Neoplastic Disease			
Cutaneous T-cell lymphoma	Adults	Uncommon	Erythematous pink-brown macules and plaques with a fine scale; poorly responsive to topical corticosteroids; variable itch (in early stages)
Langerhans cell histiocytosis	Infants	Uncommon	Scaly and purpuric dermatosis, hepatosplenomegaly, cytopenias

FLG, Filaggrin gene; *HIV*, human immunodeficiency virus.
*Common = approximately 1 in 10 to 1 in 100; uncommon = 1 in 100 to 1 in 1000; rare = 1 in 1000 to 1 in 10,000; very rare ≤ 1 in 10,000.
†Especially in developing countries.

TABLE 2 Relative Potencies of Topical Corticosteroids (from Most Potent to Weakest)

Class	Drug	Dosage Form(s)	Strength (%)
I. Very high potency			
	Augmented betamethasone dipropionate	Ointment	0.05
	Clobetasol propionate	Cream, ointment, foam	0.05
	Diflorasone diacetate	Ointment	0.05
	Halobetasol propionate	Cream, ointment	0.05
II. High potency			
	Amcinonide	Cream, lotion, ointment	0.1
	Augmented betamethasone dipropionate	Cream	0.05
	Betamethasone dipropionate	Cream, ointment, foam, solution	0.05
	Desoximetasone	Cream, ointment	0.25
	Desoximetasone	Gel	0.05
	Diflorasone diacetate	Cream	0.05
	Fluocinonide	Cream, ointment, gel, solution	0.05
	Halcinonide	Cream, ointment	0.1
	Mometasone furoate	Ointment	0.1
	Triamcinolone acetonide	Cream, ointment	0.5
III-IV. Medium potency			
	Betamethasone valerate	Cream, ointment, lotion, foam	0.1
	Clocortolone pivalate	Cream	0.1
	Desoximetasone	Cream	0.05
	Fluocinolone acetonide	Cream, ointment	0.025
	Flurandrenolide	Cream, ointment	0.05
	Fluticasone propionate	Cream	0.05
	Fluticasone propionate	Ointment	0.005
	Mometasone furoate	Cream	0.1
	Triamcinolone acetonide	Cream, ointment	0.1
V. Lower-medium potency			
	Hydrocortisone butyrate	Cream, ointment, solution	0.1
	Hydrocortisone probutate	Cream	0.1
	Hydrocortisone valerate	Cream, ointment	0.2
	Prednicarbate	Cream	0.1
VI. Low potency			
	Alclometasone dipropionate	Cream, ointment	0.05
	Desonide	Cream, gel, foam, ointment	0.05
	Fluocinolone acetonide	Cream, solution, oil	0.01
VII. Lowest potency			
	Dexamethasone	Cream	0.1
	Hydrocortisone	Cream, ointment, lotion, solution	0.25, 0.5, 1
	Hydrocortisone acetate	Cream, ointment	0.5-1

Atrial Fibrillation ALG PTG

BASIC INFORMATION

DEFINITION

Atrial fibrillation (AF) is a supraventricular tachyarrhythmia characterized by disorganized and rapid atrial activation and uncoordinated atrial contraction. AF occurs when structural and/or electrophysiologic abnormalities alter atrial tissue to promote abnormal impulse formation and/or propagation. The ventricular rate is dependent on the conduction properties of the atrioventricular (AV) node, which can be influenced by vagal/sympathetic tone, medications, or disease of the AV node.

Multiple classification schemes have been used in the past to characterize AF. The current classification scheme (divided into three major types) used by the American College of Cardiology (ACC)/American Heart Association (AHA) guideline committee is as follows:

- Paroxysmal AF: More than one episode of AF that terminate spontaneously or with intervention within 7 days
- Persistent AF: Episodes of AF that last longer than 7 days
  1. Early-persistent AF: AF that has been continuous for longer than 7 days but fewer than 3 mo
  2. Long-standing persistent AF: AF that has persisted for longer than 1 yr, either because cardioversion has failed or because cardioversion has not been attempted
- Permanent AF: When patient and physician decide to stop pursuing restoring sinus rhythm
- In addition to the previous AF categories, which are mainly defined by episode timing and termination, the ACC/AHA/European Society of Cardiology (ESC) guidelines describe additional AF categories in terms of other characteristics of the patient:
  1. Lone atrial fibrillation (LAF): Generally refers to AF in younger patients without clinical or echocardiographic evidence of cardiopulmonary disease, diabetes, or hypertension
  2. Nonvalvular AF: Atrial fibrillation in the absence of moderate-to-severe mitral stenosis or in the presence of a mechanical heart valve
  3. Secondary AF: Occurs in the setting of a primary condition that may be the cause of the AF, such as acute myocardial infarction, cardiac surgery, pericarditis, myocarditis, hyperthyroidism, pulmonary embolism, pneumonia, or other acute disease. It is considered separately because AF is less likely to recur once the precipitating condition has resolved
  4. Silent AF: Asymptomatic AF diagnosed by an ECG or rhythm strip

SYNONYMS

AF
Paroxysmal atrial fibrillation (PAF)
AFib

ICD-10CM CODES

I48.0 Paroxysmal atrial fibrillation
I48.1 Persistent atrial fibrillation
I48.2 Chronic atrial fibrillation
I48.91 Unspecified atrial fibrillation

EPIDEMIOLOGY & DEMOGRAPHICS

- The prevalence of AF increases with age, from 2% in adults <65 yr to 9% of those >65 yr.
- AF affects over 3 million people in the United States. AF is uncommon in infants and children and, when present, almost always occurs in association with structural heart disease.
- The incidence of AF is significantly higher in men than in women in all age groups (1.1% versus 0.8%). AF appears to be more common in whites than in blacks, who may have lower awareness of the disease.
- Stroke due to thromboembolism is the most common and dreaded complication of AF. The rate of ischemic stroke in patients with non-rheumatic AF averages 5% a yr, which is somewhere between 2 and 7× the rate of stroke in patients without AF. The risk of stroke is not due solely to AF; changes in the endothelium and elevated markers of inflammation that may contribute to thrombosis are found in patients with AF, regardless of their rhythm at the time. The attributable risk of stroke from AF is estimated to be 1.5% for those aged 50 to 59 yr, and it approaches 36% for those aged 80 to 89 yr.
- Table 1 summarizes the thromboembolic risk score.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Clinical presentation is variable:

- Palpitations, dizziness, or lightheadedness
- Fatigue, weakness, or impaired exercise tolerance

TABLE 1 Thromboembolic Risk Score

CHA_2DS_2-VASc Risk factors	Score
Congestive heart failure	1
Hypertension	1
Age ≥75	2
Diabetes	1
Previous stroke, TIA, or thromboembolism	2
Vascular disease	1
Age 65-75	1
Female	1

European Society of Cardiology (ESC), American Heart Association (AHA), and American College of Cardiology (ACC) Guidelines recommend to use CHA2DS2-VASc Score to assess the risk of stroke in patients with atrial fibrillation. ESC Guidelines recommend patients with risk factor(s) ≥1 to receive effective stroke prevention therapy. Antithrombotic therapy is not recommended in patients with AF (irrespective of gender) who are aged <65 and with lone AF as they have very low absolute event rates. AHA/ACC Guidelines recommend oral anticoagulation for patients with CHA2DS2-VASc ≥2; for patients with nonvalvular AF and a CHA_2DS_2-VASc score of 1, no antithrombotic therapy or treatment with an oral anticoagulant or aspirin may be considered.
CHA2DS2-VASc, Congestive heart failure, hypertension, age, diabetes, stroke/TIA, and vascular disease; *TIA,* transient ischemic attack.
From Ronco C et al: *Critical care nephrology,* ed 3, Philadelphia, 2019, Elsevier.

- Angina
- Dyspnea
- Some patients are asymptomatic
- Cardiac auscultation revealing irregularly irregular rhythm
- Thromboembolic phenomenon such as stroke

ETIOLOGY

- The most frequent change in AF is the loss of atrial muscle mass and atrial fibrosis
- Fibrillation is presumed to be caused by multiple wandering wavelets, usually originating from the pulmonary veins. Both reentrant and focal mechanisms have been proposed (Fig. 1)
- Vascular causes: Hypertensive heart disease
- Valvular heart disease
- Pulmonary causes: Pulmonary embolism, chronic obstructive pulmonary disease, obstructive sleep apnea, carbon monoxide poisoning
- Structural cardiac disease: Hypertrophic cardiomyopathy, congestive heart failure, coronary artery disease, myocardial infarction, congenital heart disease (especially those that lead to atrial enlargement such as atrial septal defect)
- Pericarditis and myocarditis
- Arrhythmias: Atrial tachycardias and atrial flutters have been associated with atrial fibrillation, as has Wolff-Parkinson-White syndrome
- Endocrine: Thyrotoxicosis, hyperthyroidism or subclinical hyperthyroidism, pheochromocytoma, obesity
- Surgery: Both cardiac and noncardiac
- Electrolytes: Hypokalemia, hypomagnesemia
- Systemic stress: Fever, anemia, hypoxia, sepsis, infections (e.g., pneumonia)
- Medications/toxins: Digitalis, adenosine, theophylline, amphetamines, cocaine, antihistamines, alcohol abuse and/or withdrawal, caffeine, steroidal antiinflammatory drugs (SAIDs), nonsteroidal antiinflammatory drugs (NSAIDs)
- Frequency of vigorous exercise is associated with an increased risk of developing AF in young men and joggers
- Porphyrias have been associated with autonomic dysfunction and increased risk of AF
- Patients with metabolic syndrome, excessive vitamin D intake, or excessive niacin intake have a higher risk of AF

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Multifocal atrial tachycardia
- Atrial flutter
- Frequent atrial premature beats
- Atrial tachycardia
- AV nodal reentry tachycardia (AVNRT)
- Wolff-Parkinson-White syndrome

WORKUP

The evaluation of atrial fibrillation involves diagnosis, determination of the etiology, and classification of the arrhythmia. A minimal evaluation

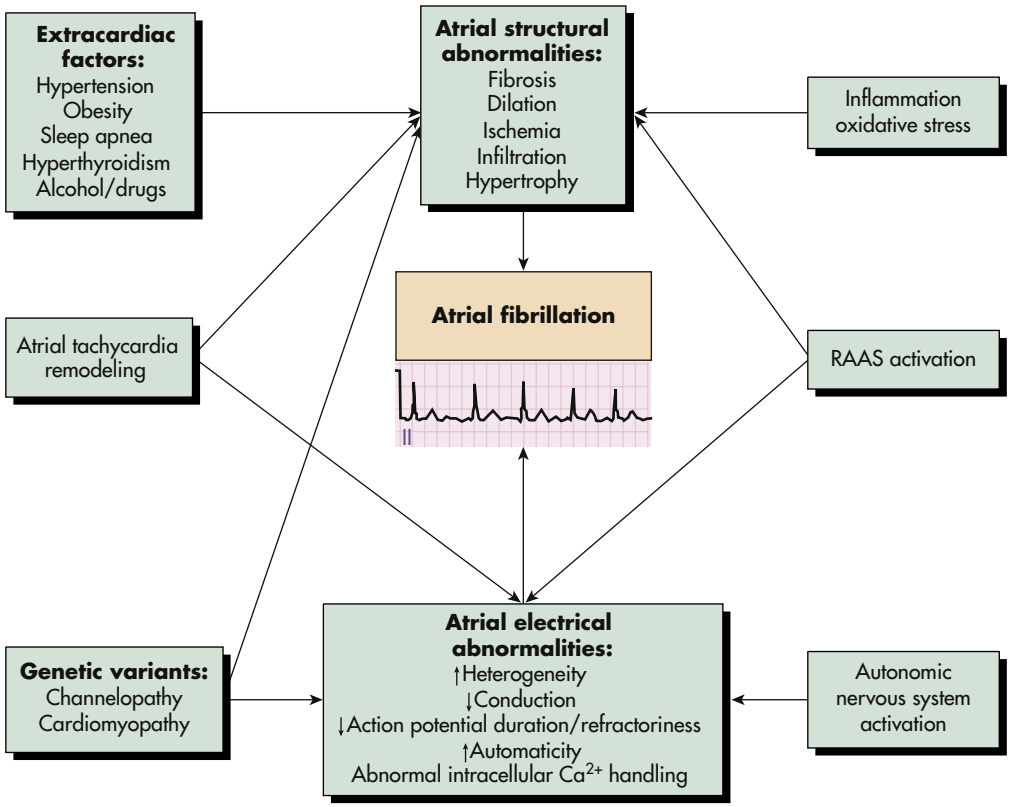

FIG. 1 Mechanisms of atrial fibrillation. *Ca^{2+},* Ionized calcium; *RAAS,* renin-angiotensin-aldosterone system. (From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult*, ed 5, Philadelphia, 2019, Elsevier.)

includes a history and physical examination, ECG, transthoracic echocardiogram, and case-specific laboratory work to rule out secondary AF.

LABORATORY TESTS

- Thyroid-stimulating hormone, free T_4
- Serum electrolytes
- Toxicity screen
- CBC count (looking for anemia, infection)
- Renal and hepatic function tests
- D-dimer/CT scan of chest pulmonary embolism protocol (if the patient has risk factors to merit a pulmonary embolism workup)

IMAGING STUDIES

- ECG (Fig. 2)
- Absence of P waves
- Fibrillatory or F waves at the isoelectric baseline with varying amplitude, morphology, and intervals (Fig. 3)
- Irregular ventricular rate
- Echocardiography to rule out structural heart disease (evaluate ventricular size, thickness, and function, atrial size, pericardial disease, and valve function)
- Chest radiography (if pulmonary disease or congestive heart failure [CHF] is suspected)
- Transesophageal echocardiography (TEE): Helpful to evaluate for left atrial thrombus (particularly in the left atrium appendage) to guide cardioversion or ablation (if thrombus is seen, cardioversion should be delayed)

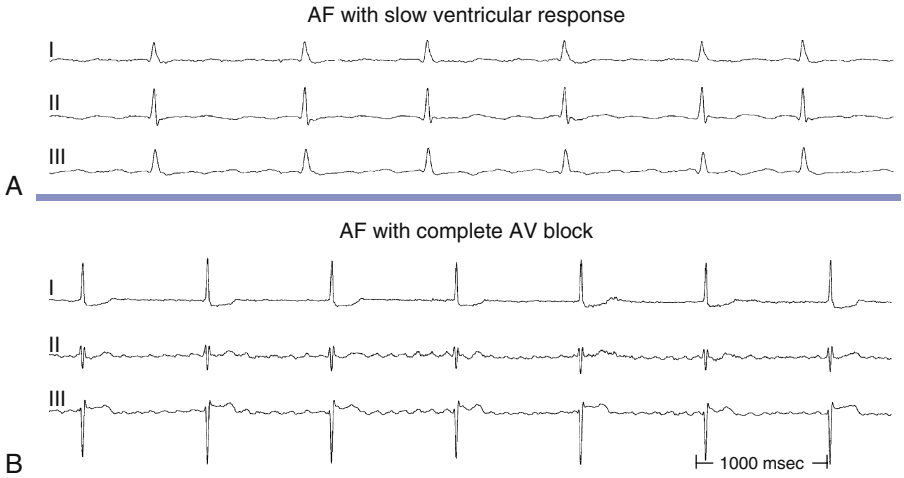

FIG. 2 Atrial fibrillation *(AF)* with slow ventricular rate. **A,** The ventricular rhythm is irregular, indicating that it is the result of conducted atrial beats. **B,** The ventricular rhythm is regular, consistent with the presence of complete atrioventricular *(AV)* block and a regular junctional escape rhythm. (From Issa Z et al: *Clinical arrhythmology and electrophysiology*, ed 2, Philadelphia, 2012, Saunders Elsevier.)

- CT and MRI: In patients with a positive D-dimer result, chest CT angiogram may be necessary to rule out pulmonary embolus. 3D imaging technologies (CT scan or MRI) are often helpful to evaluate atrial anatomy if AF ablation is planned
- 6-minute walk test or exercise test: 6-minute walk or exercise testing can help assess the adequacy of rate control. Exercise testing can also exclude ischemia prior to treatment of patients with class Ic antiarrhythmic drugs and can be used to reproduce exercise-induced AF
- Sleep study (if sleep apnea is suspected)
- Holter monitor or event recorder if the diagnosis of AF is in question and to assess AF burden
- Electrophysiologic study: When initiation of AF is secondary to a supraventricular tachycardia, such as AVNRT or Wolff-Parkinson-White syndrome

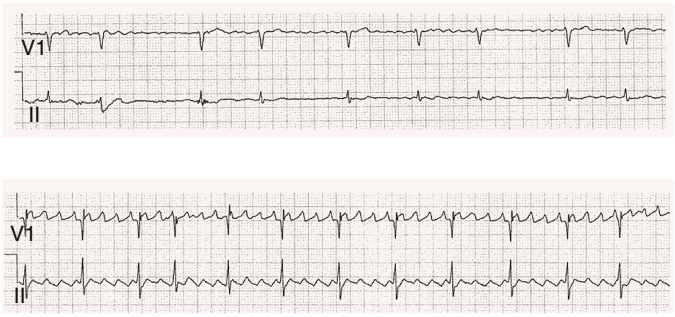

FIG. 3 Comparison between the F waves of atrial fibrillation *(top panel)* and the flutter waves of atrial flutter *(bottom panel).* Note that F waves are variable in rate, shape, and amplitude, whereas flutter waves are constant in rate and all aspects of morphology. Shown are leads V1 and II. (From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.)

Rx TREATMENT

ACUTE GENERAL Rx: New-onset AF:

- If the patient is hemodynamically unstable (hypotension, congestive heart failure, or angina), perform synchronized cardioversion after immediate conscious sedation with a rapid short-acting sedative (e.g., midazolam). The ACC/AHA recommendations for cardioversion of atrial fibrillation are summarized in Table 2. The likelihood of cardioversion-related clinical thromboembolism is low in patients with AF lasting <48 hr. Patients with AF lasting >2 days have a 5% to 7% risk for clinical thromboembolism if cardioversion is not preceded by several weeks of anticoagulation therapy. However, if transesophageal echocardiography reveals no atrial thrombus, cardioversion may be performed safely after therapeutic anticoagulation has been achieved. Alternatively, patients can be safely anticoagulated for approximately 1 mo and then undergo cardioversion without transesophageal echocardiogram. Anticoagulant therapy should be continued for at least 1 mo after cardioversion to minimize the incidence of adverse thromboembolic events. It can be stopped after 1 mo as long as AF has not recurred if the patient is deemed low risk of stroke using the Congestive heart failure, hypertension, age, diabetes, stroke/TIA, and vascular disease (CHA_2DS_2-VASc) scoring system (Table 1).
- If the patient is hemodynamically stable, a rate-control strategy is typically pursued initially. ACC/AHA recommendations for pharmacologic rate control of atrial fibrillation are summarized in Table 3.
- Treatment options for rate control include the following:
  1. Diltiazem 0.25 mg/kg (maximum of 25 mg) given intravenously (IV) over 2 min followed by a second dose of 0.35 mg/kg (maximum of 25 mg) 15 min later if the rate is not slowed to <100 beats/min. May then follow with IV infusion 10 mg/hr (range, 5 to 15 mg/hr) to achieve a resting heart rate of <100 beats/min. Onset of action after IV administration is usually within 3 min, with peak effect most often occurring within 10 min. After the ventricular rate is slowed, the patient can be changed to oral diltiazem 60 to 90 mg q4 to 6h. High doses of calcium channel blockers can exacerbate heart failure and thus should be used with caution in patients presenting with symptoms of heart failure or depressed ejection fraction.
  2. Verapamil 2.5 to 5 mg IV initially, then 5 to 10 mg IV 10 min later if the rate is still not slowed to <100 beats/min. After the ventricular rate is slowed, the patient can be changed to oral verapamil 80 to 120 mg q6 to 8h. Main concern is hypotension and heart failure with this medication, and it should not be used in patients with CHF.
  3. Esmolol and metoprolol are beta-blockers available in IV preparations that can be used. High doses of beta-blockers can have negative inotropic effects in heart failure and should be used with caution.
  4. Digoxin is not a potent AV nodal blocking agent and has a potential for toxicity and therefore cannot be relied on for acute control of the ventricular response, but it may be used in conjunction with beta-blockers and calcium channel blockers. It may be a useful adjunct to a beta-blocker in the hypotensive or heart failure patient, which is not infrequent. When used, give 0.5 mg IV loading dose (slow) and then 0.25 mg IV 6 hr later. A third dose may be needed after 6 to 8 hr; the daily dose varies from 0.125 to 0.25 mg (decrease dosage in patients with renal insufficiency and elderly patients) depending on the heart rate and signs or symptoms of digoxin toxicity. Toxicity is manifested by GI and visual complaints, atrial tachyarrhythmias, heart block, and ventricular tachycardia.
  5. Amiodarone has a class IIa recommendation from the ACC/AHA/ESC for use as a rate-controlling agent for patients who are intolerant of or unresponsive to other agents, such as patients with heart failure who may otherwise not tolerate diltiazem or metoprolol. Caution should be exercised in those who are not receiving anticoagulation because amiodarone can promote cardioversion, thereby posing a thromboembolic risk.
- AV nodal blocking agents, particularly calcium channel blockers and digoxin, should be avoided in patients with Wolff-Parkinson-White syndrome and AF because, by blocking the AV node, AF impulses may be transmitted exclusively down the accessory pathway, which can result in ventricular fibrillation. If this happens, the patient will require immediate defibrillation. Procainamide, flecainide, or amiodarone can be used instead if Wolff-Parkinson-White syndrome is suspected.
- In the acute setting, pharmacologic cardioversion (e.g., ibutilide, dofetilide) is less commonly used than electrical cardioversion. A major disadvantage with pharmacologic cardioversion is the risk of development of ventricular tachycardia and other serious arrhythmias, especially due to acute prolongation of the QT interval.
- ACC/AHA recommendations for maintenance of sinus rhythm in patients with atrial fibrillation are summarized in Table 4.

CHRONIC THERAPY

- Avoidance of alcohol in patients with suspected excessive alcohol use.
- Treatment of underlying source or cause, if any found.
- Treatment of modifiable risk factors such as obstructive sleep apnea, hypertension, and obesity have been shown to decrease AF burden in patients.
- Per the Atrial Fibrillation Follow-up Investigation of Rhythm Management (AFFIRM) and Rate Control versus Electrical Cardioversion (RACE) trials, either rate control or rhythm control strategies show no difference in composite cardiovascular end points of death, CHF, bleeding, drug side effects, or thromboembolism. Both approaches have similar outcomes as long as appropriate anticoagulation is maintained based on the individual's stroke risk.

TABLE 2 ACC/AHA Recommendations for Cardioversion of Atrial Fibrillation

Class	Indication	Level of Evidence
Pharmacologic Cardioversion		
Class I (indicated)	Administration of flecainide, dofetilide, propafenone, or ibutilide is recommended for pharmacologic cardioversion of AF.	A
Class IIa (reasonable)	Administration of amiodarone is a reasonable option for pharmacologic cardioversion of AF.	A
	A single oral bolus dose of propafenone or flecainide ("pill-in-the-pocket") can be administered to terminate persistent AF outside the hospital once treatment has proved safe in the hospital for selected patients without sinus or AV node dysfunction, bundle branch block, QT interval prolongation, the Brugada syndrome, or structural heart disease. Before antiarrhythmic medication is initiated, a beta-blocker or nondihydropyridine calcium channel antagonist should be given to prevent rapid AV conduction in the event atrial flutter occurs.	C
	Administration of amiodarone can be beneficial on an outpatient basis in patients with paroxysmal or persistent AF when rapid restoration of sinus rhythm is not deemed necessary.	C
Class IIb (may be considered)	Administration of quinidine or procainamide might be considered for pharmacologic cardioversion of AF, but the usefulness of these agents is not well established.	C
Class III (not indicated)	Digoxin and sotalol may be harmful when used for pharmacologic cardioversion of AF and are not recommended.	A
	Quinidine, procainamide, disopyramide, and dofetilide should not be started out of the hospital for conversion of AF to sinus rhythm.	B
Direct-Current Cardioversion		
Class I (indicated)	When a rapid ventricular response does not respond promptly to pharmacologic measures for patients with AF with ongoing myocardial ischemia, symptomatic hypotension, angina, or heart failure, immediate R wave–synchronized direct-current cardioversion is recommended.	C
	Immediate direct-current cardioversion is recommended for patients with AF involving preexcitation when very rapid tachycardia or hemodynamic instability occurs.	B
	Cardioversion is recommended in patients without hemodynamic instability when symptoms of AF are unacceptable to the patient. In case of early relapse of AF after cardioversion, repeated direct-current cardioversion attempts may be made after administration of antiarrhythmic medication.	C
Class IIa (reasonable)	Direct-current cardioversion can be useful to restore sinus rhythm as part of a long-term management strategy for patients with AF.	B
	The patient's preference is a reasonable consideration in the selection of infrequently repeated cardioversions for the management of symptomatic or recurrent AF.	C
Class III (not indicated)	Frequent repetition of direct-current cardioversion is not recommended for patients who have relatively short periods of sinus rhythm between relapses of AF after multiple cardioversion procedures despite prophylactic antiarrhythmic drug therapy.	C
	Electrical cardioversion is contraindicated in patients with digitalis toxicity or hypokalemia.	C
Pharmacologic Enhancement of Direct-Current Cardioversion		
Class IIa (reasonable)	Pretreatment with amiodarone, flecainide, ibutilide, propafenone, or sotalol can be useful to enhance the success of direct-current cardioversion and to prevent recurrent AF.	B
	In patients who relapse to AF after successful cardioversion, it can be useful to repeat the procedure after prophylactic administration of antiarrhythmic medication.	C
Class IIb (may be considered)	For patients with persistent AF, administration of beta-blockers, disopyramide, diltiazem, dofetilide, procainamide, or verapamil may be considered, although the efficacy of these agents to enhance the success of direct-current cardioversion or to prevent early recurrence of AF is uncertain.	C
	Out-of-hospital initiation of antiarrhythmic medications may be considered in patients without heart disease to enhance the success of cardioversion of AF.	C
	Out-of-hospital administration of antiarrhythmic medications may be considered to enhance the success of cardioversion of AF in patients with certain forms of heart disease once the safety of the drug has been verified for the patient.	C
Prevention of Thromboembolism in Patients with Atrial Fibrillation Undergoing Cardioversion		
Class I (indicated)	For patients with AF of 48-hr duration or longer, or when the duration of AF is unknown, anticoagulation (INR 2.0-3.0) is recommended for at least 3 wk before and 4 wk after cardioversion, regardless of the method (electrical or pharmacologic) used to restore sinus rhythm.	B
	For patients with AF of more than 48-hr duration requiring immediate cardioversion because of hemodynamic instability, heparin should be administered concurrently (unless contraindicated) by an initial intravenous bolus injection, followed by a continuous infusion in a dose adjusted to prolong the activated partial thromboplastin time to 1.5 to 2× the reference control value. Thereafter, oral anticoagulation (INR, 2.0-3.0) should be provided for at least 4 wk, as for patients undergoing elective cardioversion. Limited data support subcutaneous administration of low-molecular-weight heparin in this indication.	C
	For patients with AF of less than 48-hr duration associated with hemodynamic instability (angina pectoris, myocardial infarction, shock, or pulmonary edema), cardioversion should be performed immediately, without delay, for prior initiation of anticoagulation.	C

Continued

TABLE 2 ACC/AHA Recommendations for Cardioversion of Atrial Fibrillation—cont'd

Class	Indication	Level of Evidence
Class IIa (reasonable)	During the 48 hr after onset of AF, the need for anticoagulation before and after cardioversion may be based on the patient's risk of thromboembolism.	C
	As an alternative to anticoagulation before cardioversion of AF, it is reasonable to perform transesophageal echocardiography in search of thrombus in the left atrium or left atrial appendage.	B
	a. For patients with no identifiable thrombus, cardioversion is reasonable immediately after anticoagulation with unfractionated heparin (e.g., initiated by intravenous bolus injection and an infusion continued at a dose adjusted to prolong the activated partial thromboplastin time to 1.5-2× the control value until oral anticoagulation has been established with an oral vitamin K antagonist [e.g., warfarin] as evidenced by an INR ≥2.0).	B
	Thereafter, continuation of oral anticoagulation (INR, 2.0-3.0) is reasonable for a total anticoagulation period of at least 4 wk, as for patients undergoing elective cardioversion.	B
	Limited data are available to support the subcutaneous administration of a low-molecular-weight heparin in this indication.	C
	b. For patients in whom thrombus is identified by transesophageal echocardiography, oral anticoagulation (INR, 2.0-3.0) is reasonable for at least 3 wk before and 4 wk after restoration of sinus rhythm, and a longer period of anticoagulation may be appropriate even after apparently successful cardioversion because the risk of thromboembolism often remains elevated in such cases.	C
	For patients with atrial flutter undergoing cardioversion, anticoagulation can be beneficial according to the recommendations as for patients with AF.	C

ACC, American College of Cardiology; *AF,* atrial fibrillation; *AHA,* American Heart Association; *INR,* international normalized ratio.

TABLE 3 ACC/AHA Recommendations for Pharmacologic Rate Control of Atrial Fibrillation

Class	Indication	Level of Evidence
Class I (indicated)	Measurement of the heart rate at rest and control of the rate with pharmacologic agents (either a beta-blocker or nondihydropyridine calcium channel antagonist, in most cases) are recommended for patients with persistent or permanent AF.	B
	In the absence of preexcitation, intravenous administration of beta-blockers (esmolol, metoprolol, or propranolol) or nondihydropyridine calcium channel antagonists (verapamil, diltiazem) is recommended to slow the ventricular response to AF in the acute setting, exercising caution in patients with hypotension or heart failure.	B
	Intravenous administration of digoxin or amiodarone is recommended to control heart rate in patients with AF and heart failure who do not have an accessory pathway.	B
	In patients who experience symptoms related to AF during activity, the adequacy of heart rate control should be assessed during exercise, adjusting pharmacologic treatment as necessary to keep the rate in the physiologic range.	C
	Digoxin is effective after oral administration to control the heart rate at rest in patients with AF and is indicated for patients with heart failure or left ventricular dysfunction and for sedentary individuals.	C
Class IIa (reasonable)	A combination of digoxin and either a beta-blocker or nondihydropyridine calcium channel antagonist is reasonable to control the heart rate both at rest and during exercise in patients with AF. The choice of medication should be individualized and the dose modulated to avoid bradycardia.	B
	It is reasonable to use ablation of the AV node or accessory pathway to control heart rate when pharmacologic therapy is insufficient or associated with side effects.	B
	Intravenous amiodarone can be useful to control heart rate in patients with AF when other measures are unsuccessful or contraindicated.	C
	When electrical cardioversion is not necessary in patients with AF and an accessory pathway, intravenous procainamide or ibutilide is a reasonable alternative.	C
Class IIb (may be considered)	When the ventricular rate cannot be adequately controlled both at rest and during exercise in patients with AF by a beta-blocker, nondihydropyridine calcium channel antagonist, or digoxin, alone or in combination, oral amiodarone may be administered to control the heart rate.	C
	Intravenous procainamide, disopyramide, ibutilide, or amiodarone may be considered for hemodynamically stable patients with AF involving conduction over an accessory pathway	B
	When the rate cannot be controlled with pharmacologic agents or tachycardia-mediated cardiomyopathy is suspected, catheter-directed ablation of the AV node may be considered in patients with AF to control the heart rate.	C
Class III (not indicated)	Strict rate control (<80 beats/min at rest or <110 beats/min during 6-minute walk) is not beneficial compared to a resting rate <110 beats/min in asymptomatic patients with persistent AF and an ejection fraction >40%, although uncontrolled tachycardia can lead to reversible left ventricular dysfunction over time.	B
	Digitalis should not be used as the sole agent to control the rate of ventricular response in patients with paroxysmal AF.	B
	Catheter ablation of the AV node should not be attempted without a prior trial of medication to control the ventricular rate in patients with AF.	C
	In patients with decompensated heart failure and AF, intravenous administration of a nondihydropyridine calcium channel antagonist may exacerbate hemodynamic compromise and is not recommended.	C
	Intravenous administration of digitalis glycosides or nondihydropyridine calcium channel antagonists to patients with AF and a preexcitation syndrome may paradoxically accelerate the ventricular response and is not recommended.	C

TABLE 4 ACC/AHA Recommendations for Maintenance of Sinus Rhythm in Patients with Atrial Fibrillation

Class	Indication	Level of Evidence
Class I (indicated)	Before initiation of antiarrhythmic drug therapy, treatment of precipitating or reversible causes of AF is recommended.	C
	Catheter ablation by an experienced operator is useful in selected patients with symptomatic paroxysmal AF who have failed treatment with an antiarrhythmic drug and have a normal or mildly dilated left atrium and normal or mildly reduced left ventricular function.	A
Class IIa (reasonable)	Pharmacologic therapy can be useful in patients with AF to maintain sinus rhythm and to prevent tachycardia-induced cardiomyopathy.	C
	Infrequent, well-tolerated recurrence of AF is reasonable as a successful outcome of antiarrhythmic drug therapy.	C
	Outpatient initiation of antiarrhythmic drug therapy is reasonable in patients with AF who have no associated heart disease when the agent is well tolerated.	C
	In patients with lone AF without structural heart disease, initiation of propafenone or flecainide can be beneficial on an outpatient basis in patients with paroxysmal AF who are in sinus rhythm at the time of drug initiation.	B
	Sotalol can be beneficial in outpatients in sinus rhythm with little or no heart disease, prone to paroxysmal AF, if the baseline uncorrected QT interval is shorter than 460 milliseconds, serum electrolyte values are normal, and risk factors associated with class III drug–related proarrhythmia are not present.	C
	Catheter ablation is a reasonable for treatment of symptomatic persistent AF.	A
Class IIb (may be considered)	Catheter ablation may be reasonable for patients with symptomatic paroxysmal AF and significant left atrial dilation or significant left ventricular dysfunction.	A
Class III (not indicated)	Antiarrhythmic therapy with a particular drug is not recommended for maintenance of sinus rhythm in patients with AF who have well-defined risk factors for proarrhythmia with that agent.	A
	Pharmacologic therapy is not recommended for maintenance of sinus rhythm in patients with advanced sinus node disease or AV node dysfunction unless they have a functioning electronic cardiac pacemaker.	C

ACC, American College of Cardiology; *AF,* atrial fibrillation; *AHA,* American Heart Association.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

- For patients without symptomatic AF, a rate-control strategy with calcium channel blockers, beta-blockers, or digoxin is a reasonable option. The RACE 2 trial indicates that a lenient rate control strategy, with a target resting heart rate of <110 beats/min, is noninferior to a strict control strategy, with a target resting heart rate of <80 beats/min and an exercise heart rate of <110 beats/min. Most recent ACC/AHA guidelines, however, recommend targeting a heart rate <80 beats/min over a target of <110 beats/min.
- In patients with symptomatic AF, younger patients, or those with difficult to control heart rate, an attempt should be made to maintain sinus rhythm with antiarrhythmic agents. Options of antiarrhythmic agents include amiodarone, dronedarone, (paroxysmal atrial fibrillation only without heart failure), dofetilide, flecainide, propafenone (contraindicated with structural heart disease), or sotalol. The decision of which strategy to follow should be best made in consultation with a cardiologist. Use of dronedarone should be avoided in patients with persistent or permanent atrial fibrillation because of worsened cardiovascular outcomes, especially in those with concomitant symptomatic heart failure (see Fig. 4 for a proposed algorithm to guide maintenance of sinus rhythm).

NONPHARMACOLOGIC THERAPY

- Catheter ablation of AF has become a common procedure for symptomatic drug-refractory or drug-intolerant patients. Sinus rhythm can be maintained long term in the majority of patients with paroxysmal atrial fibrillation (PAF) by circumferential pulmonary vein ablation performed in experienced centers. Established centers have reported success rates of 70% to 85% in patients with paroxysmal AF, but up to 50% of patients may require more than one ablation to achieve success. Complication rates are 4.5% in the largest international survey of hospitals performing this procedure. Success with persistent AF is much lower, with long-term success rates of 40% to 50% in many studies, and such patients often require more than one procedure. The most common techniques used to isolate the pulmonary veins are radiofrequency ablation and cryoballoon ablation, which have shown similar results for patients with PAF.
- Pulmonary vein isolation is being increasingly used to treat AF in patients with heart failure. Trials have shown that pulmonary vein isolation is superior to AV node ablation with biventricular pacing in patients with heart failure who have drug-refractory AF.
- AV nodal ablation with permanent pacemaker implantation may become necessary in some patients in whom rate and rhythm are difficult to control despite drugs and cardioversion, although it is generally used as a therapy of last resort.
- The Cox-Maze III surgical procedure, with its modifications creating electrical barriers to the macroreentrant circuits that are believed to underlie AF, is being performed with good results in some medical centers (preservation of sinus rhythm in 70% to 95% of patients without the use of long-term antiarrhythmic medication). Success rates are higher in paroxysmal than in persistent or permanent atrial fibrillation. Surgical ablation is often used for patients undergoing aortic or mitral valve surgery. As a stand-alone procedure, it is a Class IIb recommendation per ACC/AHA Guidelines in 2017. Some centers perform surgical pulmonary vein isolation similar to this procedure using a mini-thoracotomy or video thoracoscopic "Mini-Maze" approach. Another surgical method is a pericardioscopic approach that allows extensive posterior wall ablation and, when combined with catheter ablation in a "hybrid" approach, has shown promising results for patients with persistent AF.
- It is important to understand that ablation therapy will not eliminate the need to take anticoagulant drugs. Even after ablation,

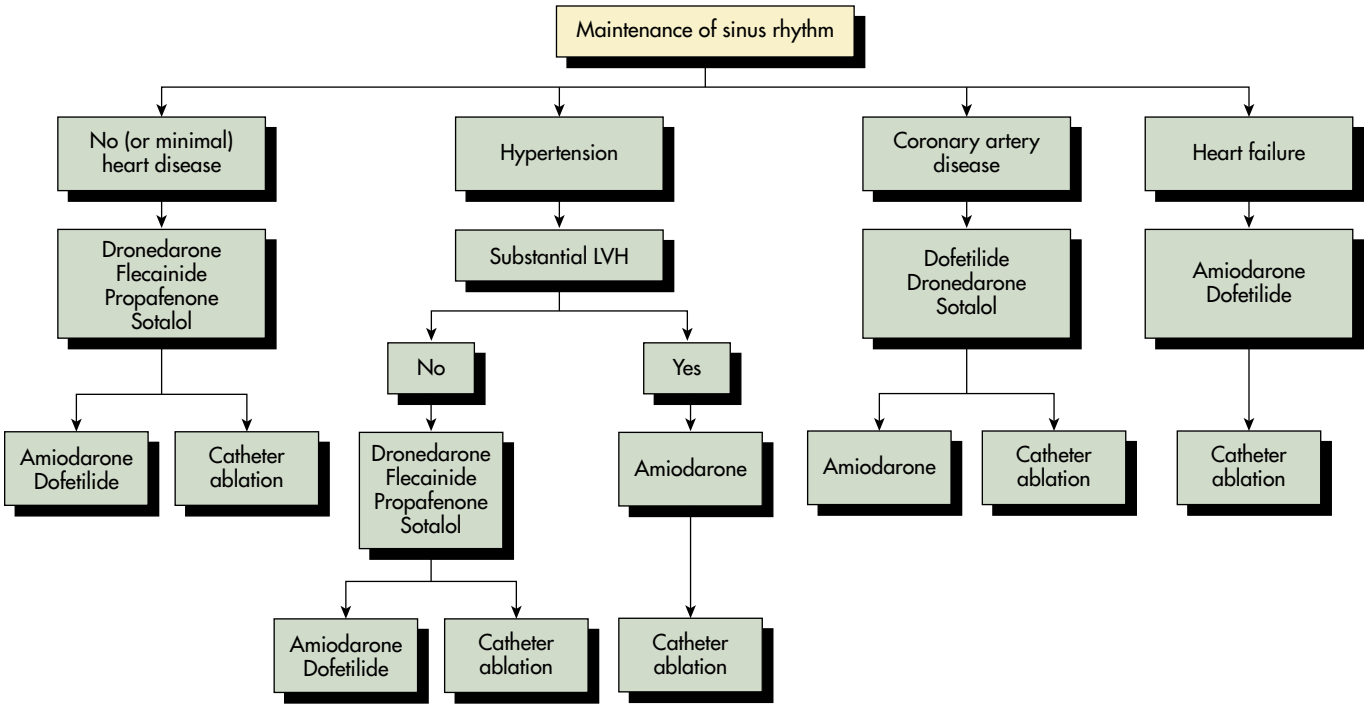

FIG. 4 Therapy to maintain sinus rhythm in patients with recurrent paroxysmal or persistent atrial fibrillation. Drugs are listed alphabetically and not in order of suggested use. The seriousness of heart disease progresses from left to right, and selection of therapy in patients with multiple conditions depends on the most serious condition present. *LVH,* Left ventricular hypertrophy. (From Wann LS et al: 2011 ACCF/AHA/HRS Focused update on the management of patients with atrial fibrillation [updating the 2006 guideline]: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines, *J Am Coll Cardiol* 57[2]:223-242, 2011.)

patients with AF face increased risk of thromboembolic events and most electrophysiologists suggest lifelong anticoagulation for patients with elevated stroke risk score. Due to the increasing success rate of ablation, catheter-based therapy is considered the first-line treatment for paroxysmal AF patients intolerant or refectory to one medication or IIa for persistent patients in the ACC/AHA AF Ablation Guidelines in 2017. It remains a IIb indication for patients in long-standing persistent atrial fibrillation.

STROKE PREVENTION

- The decision whether to pursue long-term anticoagulation must be made in light of the patient's risk for a cardioembolic event versus risk for a bleeding event. ACC/AHA recommendations for prevention of thromboembolism in atrial fibrillation are summarized in Table 5. In nonvalvular AF, CHA2DS2-VASc has superseded the CHADS2 scoring system (C = congestive heart failure; H = hypertension; A = age [>75 yr is 2 points]; D = diabetes; S = stroke, transient ischemic attack, or thromboembolic disease [2 points]; V = vascular disease, A = age 65-74 yr; and Sc = sex category, with females getting 1 extra point). Patients with a CHA2DS2-VASc score of 0 are considered low risk, 1 to 2 are considered moderate risk, and >2 are considered high risk. Per guidelines, patients with a score of 0 do not merit anticoagulation. Patients with a score of 1 can be treated at the discretion of the physician with either aspirin or an oral anticoagulant (warfarin or a novel oral anticoagulant). Anticoagulation with either warfarin or a novel oral anticoagulant is recommended for all men with a CHADS2-VASc score of 2 or above and women with a CHADS2-VASc score of 3 or above. The available direct-acting oral anticoagulants (DOACs) are recommended over warfarin in DOAC-eligible patients with atrial fibrillation in the new 2019 AHA/ACC/Heart Rhythm Society (HRS) Focused Update of the 2014 AHA/ACC/HRS Guidelines.
- Increasing amounts of evidence now show that aspirin likely does not protect a person from stroke in AF and has recently been dropped from most of the ACC/AHA and European Atrial Fibrillation guidelines. Target INR for patients on warfarin with an indication for anticoagulation is 2 to 3 and should be diligently monitored to avoid risk of stroke versus bleeding. Patients with hypertrophic cardiomyopathy or thyrotoxicosis with AF also have a high risk of stroke and should be anticoagulated irrespective of their CHADS2-VASc score.
- The DOACs include several factor Xa inhibitors (Table 6) and a direct thrombin inhibitor.
  1. Dabigatran is a direct thrombin inhibitor indicated to reduce the risk of stroke and systemic embolism in patients with nonvalvular atrial fibrillation. In the RE-LY trial of 18,113 patients with mean CHADS2 score of 2.1, dabigatran 110 mg bid was noninferior to warfarin, and 150 mg bid was superior to warfarin in prevention of thromboembolic events. Bleeding risk was similar to that of warfarin for both doses. Idarucizumab has been approved as a dabigatran reversal agent. Onset is immediate, and it provides full reversal for at least 24 hr in most patients.
  2. Factor Xa inhibitors (apixaban, rivaroxaban, edoxaban) are also effective in reducing stroke and systemic embolism in patients with atrial fibrillation. The Apixaban for Reduction in Stroke and Other Thromboembolic Events in Atrial Fibrillation (ARISTOTLE) trial in patients at high risk for stroke (mean CHADS2 score 2.1) using apixaban, the Rivaroxaban Once Daily Oral Direct Factor Xa Inhibition Compared with Vitamin K Antagonism for Prevention of Stroke and Embolism Trial in Atrial Fibrillation (ROCKET AF) trial using rivaroxaban in patients with

TABLE 5 ACC/AHA Recommendations for Prevention of Thromboembolism in Atrial Fibrillation

Class	Indication	Level of Evidence
Class I (indicated)	Antithrombotic therapy to prevent thromboembolism is recommended for all patients with AF, except those with lone AF or contraindications.	A
	The selection of the antithrombotic agent should be based on the absolute risks of stroke and bleeding and the relative risk and benefit for a given patient.	A
	For patients without mechanical heart valves at high risk of stroke, chronic oral anticoagulant therapy with a vitamin K antagonist is recommended in a dose adjusted to achieve the target intensity international normalized ratio (INR) of 2.0-3.0 unless contraindicated. Factors associated with highest risk for stroke in patients with AF are prior thromboembolism (stroke, transient ischemic attack, or systemic embolism) and rheumatic mitral stenosis.	A
	Anticoagulation with a vitamin K antagonist is recommended for patients with more than one moderate risk factor. Such factors include age ≥75 yr, hypertension, heart failure, impaired left ventricular systolic function (ejection fraction ≤35% or fractional shortening <25%), and diabetes mellitus.	A
	INR should be determined at least weekly during initiation of therapy and monthly when anticoagulation is stable.	A
	Dabigatran is a useful alternative to warfarin in patients with AF and risk factors for stroke who do not have a prosthetic heart valve or significant valve disease, a creatinine clearance <15 ml/min, or advanced liver disease.	B
	Aspirin, 81-325 mg daily, is recommended as an alternative to vitamin K antagonists in low-risk patients or in those with contraindications to oral anticoagulation.	A
	For patients with AF who have mechanical heart valves, the target intensity of anticoagulation should be based on the type of prosthesis, maintaining an INR of at least 2.5.	B
	Antithrombotic therapy is recommended for patients with atrial flutter as for those with AF.	C
Class IIa (reasonable)	For primary prevention of thromboembolism in patients with nonvalvular AF who have just one of the following validated risk factors, antithrombotic therapy with either aspirin or a vitamin K antagonist is reasonable, based on an assessment of the risk of bleeding complications, ability to safely sustain adjusted chronic anticoagulation, and the patient's preferences: Age ≥75 yr (especially in female patients), hypertension, heart failure, impaired left ventricular function, or diabetes mellitus	A
	For patients with nonvalvular AF who have one or more of the following less well-validated risk factors, antithrombotic therapy with either aspirin or a vitamin K antagonist is reasonable for prevention of thromboembolism: Age 65-74 yr, female gender, or coronary artery disease. The choice of agent should be based on the risk of bleeding complications, ability to sustain adjusted chronic anticoagulation, and the patient's preferences.	B
	It is reasonable to select antithrombotic therapy by the same criteria irrespective of the pattern (i.e., paroxysmal, persistent, or permanent) of AF.	B
	In patients with AF who do not have mechanical prosthetic heart valves, it is reasonable to interrupt anticoagulation for up to 1 wk without substituting heparin for surgical or diagnostic procedures that carry a risk of bleeding.	C
	It is reasonable to reevaluate the need for anticoagulation at regular intervals.	C
Class IIb (may be considered)	In patients ≥75 yr at increased risk of bleeding but without frank contraindications to oral anticoagulant therapy, and in other patients with moderate risk factors for thromboembolism who are unable to safely tolerate anticoagulation at the standard intensity of INR 2.0-3.0, a lower INR target of 2.0 (range, 1.6-2.5) may be considered for prevention of ischemic stroke and systemic embolism.	C
	When surgical procedures require interruption of oral anticoagulant therapy for longer than 1 wk in high-risk patients, unfractionated heparin may be administered or low-molecular-weight heparin given by subcutaneous injection, although the efficacy of these alternatives in this situation is uncertain.	C
	After percutaneous coronary intervention or revascularization surgery in patients with AF, low-dose aspirin (<100 mg/day) and/or clopidogrel (75 mg/day) may be given concurrently with anticoagulation to prevent myocardial ischemic events, but these strategies have not been thoroughly evaluated and are associated with an increased risk of bleeding.	C
	In patients undergoing percutaneous coronary intervention, anticoagulation may be interrupted to prevent bleeding at the site of peripheral arterial puncture, but the vitamin K antagonist should be resumed as soon as possible after the procedure and the dose adjusted to achieve an INR in the therapeutic range. Aspirin may be given temporarily during the hiatus, but the maintenance regimen should then consist of the combination of clopidogrel, 75 mg daily, plus warfarin (INR, 2.0-3.0). Clopidogrel should be given for a minimum of 1 mo after implantation of a bare-metal stent, at least 3 mo for a sirolimus-eluting stent, at least 6 mo for a paclitaxel-eluting stent, and 12 mo or longer in selected patients, following which warfarin may be continued as monotherapy in the absence of a subsequent coronary event. When warfarin is given in combination with clopidogrel or low-dose aspirin, the dose intensity must be carefully regulated.	C
	In patients with AF younger than 60 yr without heart disease or risk factors for thromboembolism (lone AF), the risk of thromboembolism is low without treatment, and the effectiveness of aspirin for primary prevention of stroke relative to the risk of bleeding has not been established.	C
	In patients with AF who sustain ischemic stroke or systemic embolism during treatment with low-intensity anticoagulation (INR, 2.0-3.0), rather than add an antiplatelet agent, it may be reasonable to raise the intensity of the anticoagulation to a maximum target INR of 3.0-3.5.	C
	Clopidogrel plus aspirin may be considered in patients who cannot tolerate or who refuse an oral anticoagulant.	B
Class III (not indicated)	Long-term anticoagulation with a vitamin K antagonist is not recommended for primary prevention of stroke in patients younger than 60 yr without heart disease (lone AF) or any risk factors for thromboembolism.	C

HAS-BLED is the most validated bleeding score for patients with AF in whom antithrombotic therapy is indicated. When HAS-BLED score ≥3, caution and regular review are appropriate, as well as efforts to correct the potentially reversible risk factors for bleeding.
INRs, International normalized ratio.
From Ronco C et al: *Critical care nephrology,* ed 3, Philadelphia, 2019, Elsevier.

CHADS2 score 3.5, and the Effective Anticoagulation with Factor Xa Next Generation in Atrial Fibrillation (ENGAGE-AF) trial using edoxaban in patients with a CHADS2 score of at least 2, showed that these anticoagulants reduce the risk of stroke, systemic embolism, and serious bleeding compared with warfarin. Rivaroxaban showed noninferior efficacy to warfarin in prevention of thromboembolism. Apixaban showed superior stroke reduction, reduced bleeding events, and an overall mortality benefit when compared with warfarin. Edoxaban showed noninferiority to warfarin with respect to stroke and systemic embolism prevention, with lower rates of bleeding and death from cardiovascular causes, but benefit was limited to patients with moderately impaired renal function. Rivaroxaban and edoxaban are dosed once a day, and apixaban is dosed twice a day. A factor Xa reversal agent, andexanet alfa, has received FDA approval as a reversal for the anticoagulant effect of these agents.

- The decision to anticoagulate should be made irrespective of whether the atrial fibrillation is paroxysmal, persistent, or permanent.
- For patients in whom anticoagulation with warfarin or other anticoagulants is contraindicated due to high bleeding risk (Table 7), left atrial appendage exclusion is an alternative. Several methods can be used, including the Lariat procedure and the AtriClip, but these are still considered unproven for stroke prevention in AF. The Watchman device is a left atrial appendage occlusion device and is the only device approved by the FDA for stroke prevention specifically for patients with AF that require anticoagulation but have an appropriate reason to seek an alternative. Patients with surgical ligation of the left atrial appendage still have an indication for anticoagulation due to lack of clinical trials showing a stroke risk reduction and inconsistent techniques.
- Perioperative bridging anticoagulation in patients with AF: Current guidelines advise perioperative continuation of warfarin in low-risk patients (CHADS2 score 0 to 2) and bridging anticoagulation only in those at highest risk of thromboembolism (CHADS2 score 5 to 6). The recent Bridging Anticoagulation in Patients who Require Temporary Interruption of Warfarin Therapy for an Elective Invasive Procedure or Surgery (BRIDGE) Study found that for patients who require procedure-related warfarin interruption, forgoing bridging anticoagulation was noninferior to perioperative bridging with low molecular weight heparin and decrease the risk of major bleeding. Based on this study, a no-bridging strategy is appropriate for lower-risk AF and minor procedures but in high-risk patients having major surgery the answer remains debatable.

PROGNOSIS

- AF is associated with a 1.5- to 1.9-fold higher risk of death, which is in part due to the strong association between AF and thromboembolic events.
- AF is also independently associated with an increased risk of incident myocardial infarction, especially in women and blacks.
- Development of AF predicts heart failure and is associated with a worse New York Heart Association Heart Failure classification. AF may also worsen heart failure in individuals who are dependent on the atrial component of the cardiac output.
- AF in the setting of acute myocardial infarction was associated with a 40% increase in mortality compared to patients in sinus rhythm.
- ACC/AHA recommendations for special considerations in atrial fibrillation are summarized in Table 8.

DISPOSITION

Factors associated with maintenance of sinus rhythm after cardioversion include:
- Left atrium diameter <60 mm
- Absence of mitral valve disease
- Short duration of AF

REFERRAL

Refer to a cardiologist those patients in whom antiarrhythmic therapy or catheter-based/surgical intervention is being considered.

PEARLS & CONSIDERATIONS

COMMENTS

The number of patients anticoagulated in the United States is approximately half the amount that should be anticoagulated for AF, resulting in a large burden of stroke. The exact burden of AF needed to trigger the need for anticoagulation is not known, though recent pacemaker trials have suggested that as little as 6 min confers significant stroke risk. Reversal agents for the new class of anticoagulation are now available: Idarucizumab for reversal of dabigatran; andexanet alfa for reversal of apixaban and rivaroxaban (pending FDA approval).

The American Academy of Family Physicians and the American College of Physicians provide the following recommendations for the management of newly detected AF:
- Rate control with chronic anticoagulation is the recommended strategy for the majority

TABLE 8 ACC/AHA Recommendations for Special Considerations in Atrial Fibrillation

Class	Indication	Level of Evidence
Postoperative Atrial Fibrillation		
Class I (indicated)	Unless contraindicated, treatment with an oral beta-blocker to prevent postoperative AF is recommended for patients undergoing cardiac surgery.	A
	Administration of AV nodal blocking agents is recommended to achieve rate control in patients who develop postoperative AF.	B
Class IIa (reasonable)	Preoperative administration of amiodarone reduces the incidence of AF in patients undergoing cardiac surgery and represents appropriate prophylactic therapy for patients at high risk for postoperative AF.	A
	It is reasonable to restore sinus rhythm by pharmacologic cardioversion with ibutilide or direct-current cardioversion in patients who develop postoperative AF, as advised for nonsurgical patients.	B
	It is reasonable to administer antiarrhythmic medications in an attempt to maintain sinus rhythm in patients with recurrent or refractory postoperative AF, as recommended for other patients who develop AF.	B
	It is reasonable to administer antithrombotic medication in patients who develop postoperative AF, as recommended for nonsurgical patients.	B
Class IIb (may be considered)	Prophylactic administration of sotalol may be considered for patients at risk for development of AF after cardiac surgery.	B
Acute Myocardial Infarction		
Class I (indicated)	Direct-current cardioversion is recommended for patients with severe hemodynamic compromise or intractable ischemia, or when adequate rate control cannot be achieved with pharmacologic agents in patients with acute myocardial infarction and AF.	C
	Intravenous administration of amiodarone is recommended to slow a rapid ventricular response to AF and to improve left ventricular function in patients with acute myocardial infarction.	C
	Intravenous beta-blockers and nondihydropyridine calcium antagonists are recommended to slow a rapid ventricular response to AF in patients with acute myocardial infarction who do not display clinical left ventricular dysfunction, bronchospasm, or AV block.	C
	For patients with AF and acute myocardial infarction, administration of unfractionated heparin by either continuous intravenous infusion or intermittent subcutaneous injection is recommended in a dose sufficient to prolong the activated partial thromboplastin time to 1.5-2× the control value, unless contraindications to anticoagulation exist.	C
Class IIa (reasonable)	Intravenous administration of digitalis is reasonable to slow a rapid ventricular response and to improve left ventricular function in patients with acute myocardial infarction and AF associated with severe left ventricular dysfunction and heart failure.	C
Class III (not indicated)	The administration of class IC antiarrhythmic drugs is not recommended in patients with AF in the setting of acute myocardial infarction.	C
Management of Atrial Fibrillation Associated with Wolff-Parkinson-White (WPW) Preexcitation Syndrome		
Class I (indicated)	Catheter ablation of the accessory pathway is recommended for symptomatic patients with AF who have WPW syndrome, particularly those with syncope due to rapid heart rate or those with a short bypass tract refractory period.	B
	Immediate direct-current cardioversion is recommended to prevent ventricular fibrillation in patients with a short anterograde bypass tract refractory period in whom AF occurs with a rapid ventricular response associated with hemodynamic instability.	B
	Intravenous procainamide or ibutilide is recommended to restore sinus rhythm in patients with WPW in whom AF occurs without hemodynamic instability in association with a wide QRS complex on the electrocardiogram (≥120-msec duration) or with a rapid preexcited ventricular response.	C
Class IIa (reasonable)	Intravenous flecainide or direct-current cardioversion is reasonable when very rapid ventricular rates occur in patients with AF involving conduction over an accessory pathway.	B
Class IIb (may be considered)	It may be reasonable to administer intravenous quinidine, procainamide, disopyramide, ibutilide, or amiodarone to hemodynamically stable patients with AF involving conduction over an accessory pathway.	B
Class III (not indicated)	Intravenous administration of digitalis glycosides or nondihydropyridine calcium channel antagonists is not recommended in patients with WPW syndrome who have preexcited ventricular activation during AF.	B
Hyperthyroidism		
Class I (indicated)	Administration of a beta-blocker is recommended to control the rate of ventricular response in patients with AF complicating thyrotoxicosis, unless contraindicated.	B
	In circumstances when a beta-blocker cannot be used, administration of a nondihydropyridine calcium channel antagonist (diltiazem or verapamil) is recommended to control the ventricular rate in patients with AF and thyrotoxicosis.	B
	In patients with AF associated with thyrotoxicosis, oral anticoagulation (INR, 2.0-3.0) is recommended to prevent thromboembolism, as recommended for AF patients with other risk factors for stroke.	C
	Once a euthyroid state is restored, recommendations for antithrombotic prophylaxis are the same as for patients without hyperthyroidism.	C

TABLE 8 ACC/AHA Recommendations for Special Considerations in Atrial Fibrillation—cont'd

Class	Indication	Level of Evidence
Management of Atrial Fibrillation during Pregnancy		
Class I (indicated)	Digoxin, a beta-blocker, or a nondihydropyridine calcium channel antagonist is recommended to control the rate of ventricular response in pregnant patients with AF.	C
	Direct-current cardioversion is recommended in pregnant patients who become hemodynamically unstable because of AF.	C
	Protection against thromboembolism is recommended throughout pregnancy for all patients with AF (except those with lone AF and/or low thromboembolic risk). Therapy (anticoagulant or aspirin) should be chosen according to the stage of pregnancy.	C
Class IIb (may be considered)	Administration of heparin may be considered during the first trimester and last month of pregnancy for patients with AF and risk factors for thromboembolism. Unfractionated heparin may be administered either by continuous intravenous infusion in a dose sufficient to prolong the activated partial thromboplastin time to 1.5-2× the control value or by intermittent subcutaneous injection in a dose of 10,000-20,000 units every 12 hr, adjusted to prolong the midinterval (6 hr after injection) activated partial thromboplastin time to 1.5× control.	B
	Despite the limited data available, subcutaneous administration of low-molecular-weight heparin may be considered during the first trimester and last month of pregnancy for patients with AF and risk factors for thromboembolism.	C
	Administration of an oral anticoagulant may be considered during the second trimester for pregnant patients with AF at high thromboembolic risk.	C
	Administration of quinidine or procainamide may be considered to achieve pharmacologic cardioversion in hemodynamically stable patients who develop AF during pregnancy.	C
Management of Atrial Fibrillation in Patients with Hypertrophic Cardiomyopathy (HCM)		
Class I (indicated)	Oral anticoagulation (INR, 2.0-3.0) is recommended in patients with HCM who develop AF, as for other patients at high risk of thromboembolism.	B
Class IIa (may be considered)	Antiarrhythmic medications can be useful to prevent recurrent AF in patients with HCM. Available data are insufficient to recommend one agent over another in this situation, but (a) disopyramide combined with a beta-blocker or nondihydropyridine calcium channel antagonist or (b) amiodarone alone is generally preferred.	C
Management of Atrial Fibrillation in Patients with Pulmonary Disease		
Class I (indicated)	Correction of hypoxemia and acidosis is the recommended primary therapeutic measure for patients who develop AF during an acute pulmonary illness or exacerbation of chronic pulmonary disease.	C
	A nondihydropyridine calcium channel antagonist (diltiazem or verapamil) is recommended to control the ventricular rate in patients with obstructive pulmonary disease who develop AF.	C
	Direct-current cardioversion should be attempted in patients with pulmonary disease who become hemodynamically unstable as a consequence of AF.	C
Class III (not indicated)	Theophylline and beta-adrenergic agonist agents are not recommended for patients with bronchospastic lung disease who develop AF.	C
	Beta-blockers, sotalol, propafenone, and adenosine are not recommended in patients with obstructive lung disease who develop AF.	C

of asymptomatic patients with chronic AF. Rhythm control has not been shown to be superior to rate control (with chronic anticoagulation) in reducing morbidity and mortality, and may be inferior in some patient subgroups to rate control. Rhythm control is appropriate when based on other special considerations, such as patient symptoms, exercise tolerance, and patient preference.

- Patients with AF should receive chronic anticoagulation, unless they are at low risk for stroke as stated earlier or have specific contraindications.
- For patients with AF, the following drugs are recommended for their demonstrated efficacy in rate control during exercise and while at rest: Atenolol, metoprolol, diltiazem, and verapamil (drugs listed alphabetically by class). Digoxin is effective only for rate control at rest and, therefore, should be used only as a second-line agent for rate control in AF.
- For patients who elect to undergo acute cardioversion to achieve sinus rhythm in AF, both direct-current cardioversion and pharmacologic conversion are appropriate options in an otherwise healthy patient.
- Both transesophageal echocardiography with short-term prior anticoagulation followed by early acute cardioversion (in absence of intracardiac thrombus) with postcardioversion anticoagulation vs. delayed cardioversion with preanticoagulation and postanticoagulation are appropriate management strategies for patients who elect to undergo cardioversion.
- Among patients with paroxysmal AF without previous antiarrhythmic drug treatment, ablation compared with antiarrhythmic drugs resulted in a lower rate of recurrent atrial tachyarrhythmias at 2 yr. However, recurrence was frequent in both groups.
- Among patients with atrial fibrillation who undergo packed cell volume, the risk of bleeding is lower among those who receive dual therapy with dabigatran and a $P2Y_{12}$ inhibitor (clopidogrel or ticagrelor) than among those who receive triple therapy with warfarin, a $P2Y_{12}$ inhibitor, and aspirin. Dual therapy has been shown to be noninferior to triple therapy with respect to the risk of thromboembolic events.[1]
- In patients with atrial fibrillation and stable coronary artery disease, rivaroxaban

[1]Cannon CP et al: Dual antithrombotic therapy with dabigatran after PCV in atrial fibrillation, *N Engl J Med* 377:1513-1524, 2017.

monotherapy is noninferior to combination therapy with rivaroxaban plus a single antiplatelet agent for efficacy and superior for safety.[2]

- In patients presenting to the ED with recent-onset, symptomatic atrial fibrillation, a wait-and-see approach is noninferior to early cardioversion in achieving a return to sinus rhythm at 4 weeks.[3]

Atrial Flutter PTG

BASIC INFORMATION

DEFINITION

Typical atrial flutter is the term commonly applied to the atrial macroreentrant circuit that circulates around the tricuspid annulus in the right atrium. The critical isthmus of the circuit is the tissue between the inferior vena cava and the tricuspid annulus, and a more precise name for this arrhythmia is *cavotricuspid isthmus-dependent atrial flutter*, or CTI flutter. Because of its anatomic and physiologic stability, the result is regular atrial depolarizations, typically at a rate of 250 to 350 beats/min. Regular, macroreentrant atrial arrhythmias at this rate that do not use the CTI are referred to as *atypical atrial flutter*. Because of the circuit's stability, conduction through the atrioventricular node (AVN) is often predictable at a common mathematical denominator. For example, when the flutter rate is 300 beats/min, 2:1 conduction results in a ventricular rate of 150 beats/min. By extension, 3:1 conduction results in a ventricular rate of 100 beats/min, 4:1 in a rate of 75 beats/min, and 5:1 in a rate of 60 beats/min. If the regular atrial impulses conduct at a variable rate through the AVN, the result may be an irregular QRS pattern. Table E1 summarizes the different types of atrial flutter and distinguishing features on scalar electrocardiography.

ICD-10CM CODES

I48.3	Typical atrial flutter
I48.4	Atypical atrial flutter
I48.92	Unspecified atrial flutter

EPIDEMIOLOGY & DEMOGRAPHICS

- Atrial flutter is the second most common atrial tachyarrhythmia after atrial fibrillation, with an estimated 200,000 new cases annually in the U.S.
- Atrial flutter is common in patients with congestive heart failure, chronic obstructive pulmonary disease (COPD), or during the first wk after open heart surgery.
- Atrial flutter occurs more frequently with advancing age (5/10,0000 age <50 vs. 587/100,000 age >80 yr) and 2.5 times more frequently in men than in women.
- Patients taking antiarrhythmics for chronic suppression of atrial fibrillation may convert to atrial flutter.
- Atrial flutter is typically seen in patients with underlying structural heart disease and is uncommon in children or young adults.
- More than 50% of patients with atrial flutter will develop atrial fibrillation in 3 yr, and more than 80% will develop atrial fibrillation within 5 yr. This is important when considering treatment options for atrial flutter and future considerations around anticoagulation.

CLASSIFICATION

Historically, the Wells classification designated atrial flutter as type I and type II. However, it is now recognized that tachycardias satisfying either of the definitions for type I or type II can be caused by reentrant circuits or by rapid focal atrial tachycardia, and this classification is infrequently used. Designating atrial flutter based on whether or not it is CTI dependent is more useful because of the management (i.e., ablation) options. Type I CTI-dependent atrial flutter, also known as common atrial flutter or typical atrial flutter, has an atrial rate of 240 to 350 beats/min. The reentrant loop circles the right atrium, passing through the CTI, a body of fibrous tissue in the lower atrium between the inferior vena cava and the tricuspid valve. CTI flutter can revolve around the tricuspid annulus in either direction (counterclockwise or clockwise) when viewing the tricuspid annulus *en face*.

- Counterclockwise atrial flutter is the more common type (~75%). The flutter waves are "sawtooth" and negative on the surface ECG leads II, III, and aVF; positive in V1; and negative in V6. (Fig. 1)
- Clockwise atrial flutter is less common (~25%): The reentry loop cycles in the opposite direction; thus, the flutter waves are upright in leads II, III, and aVF; negative in V1; and positive in V6. (Fig. 2)

Atypical atrial flutter is defined by absence of CTI dependence and may occur in patients with prior cardiac surgery, congenital heart disease, or prior radiofrequency ablation (especially left atrial ablation for atrial fibrillation) or may be idiopathic. One ECG feature is the lack of discordance between the inferior leads (leads II, III, and aVF) and V1. Flutter circuits in the left atrium often have upright flutter waves in all precordial leads.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Palpitations
- Dizziness, lightheadedness, syncope, or near syncope
- Angina
- Congestive heart failure
- Embolic phenomena from intracardiac thrombus

ETIOLOGY

- Age-related degenerative changes
- Rheumatic heart disease
- Congenital heart disease
- Left ventricular dysfunction or congestive heart failure
- Acute myocardial infarction (rarely)
- Thyrotoxicosis
- Pulmonary embolism
- Mitral valve disease
- Cardiac surgery
- Chronic obstructive pulmonary disease
- Obesity
- Pericarditis
- Pulmonary hypertension
- Antiarrhythmic therapy use in patients with atrial fibrillation

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Atrial fibrillation
- Atrial tachycardia
- Supraventricular tachycardia:
  1. Atrioventricular node reentry
  2. Orthodromic reciprocating tachycardia (using a concealed bypass tract)
  3. Junctional ectopic tachycardia
  4. Wolff-Parkinson-White syndrome
- Sinus tachycardia

WORKUP

- ECG
- Laboratory evaluation
- Assessment of CHA_2DS_2-VaSc score

LABORATORY TESTS

- Thyroid function studies
- Serum electrolytes, including renal and hepatic tests (anticipating antiarrhythmic therapy use)

IMAGING STUDIES

- ECG:
  1. Absence of P waves
  2. Regular, "sawtooth," or "F" (flutter) wave pattern without an isoelectric baseline in leads II, III, and aVF (seen most commonly with counterclockwise typical CTI-flutter)
  3. There is rarely 1:1 atrioventricular (AV) conduction in atrial flutter (unless preexcitation is present). Rather, AV conduction is usually in a 2:1 (Fig. 1), 3:1, or 4:1 fashion, with corresponding usual ventricular rates of 150, 100, or 75 beats/min, respectively (assuming an atrial rate of 300 beats/min). With high vagal tone or AV block, ventricular rates may be slow in atrial flutter.
- Echocardiography (for new diagnoses) to evaluate for structural heart disease (ventricular size, thickness, and function; atrial size, and valve function).
- Transesophageal echocardiography: Consider in patients with associated structural or functional heart disease to ascertain the presence of intracardiac thrombi, in the absence of an appropriate duration of anticoagulation.
- Holter monitoring or event recorder to assess for paroxysmal atrial flutter or rate control or to identify the arrhythmia if symptoms are nonspecific or to identify triggering events.
- Electrophysiologic studies: Required for a precise diagnosis, for mapping pathway, and for ablation.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Vagal maneuvers (e.g., the Valsalva maneuver or carotid sinus massage) may transiently slow the ventricular rate (by increasing AV block) and may make flutter waves more

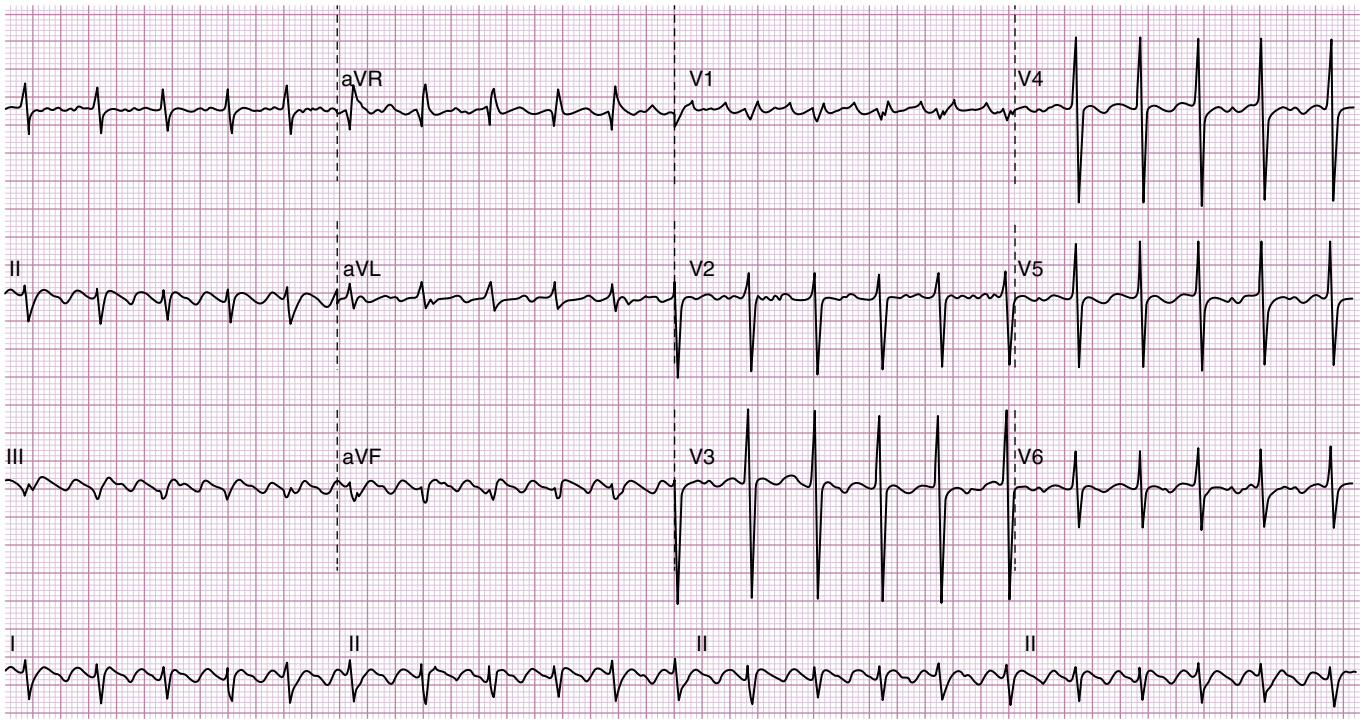

FIG. 1 Counterclockwise atrial flutter with 2:1 atrioventricular conduction. Note the negative flutter waves in leads II, III, and F, positive in V1 and negative in V6. The second flutter wave can be seen overlying the QRS in the inferior leads and at the end of the QRS in lead V1. *aVF,* Augmented vector foot; *aVL,* augmented vector left; *aVR,* augmented vector right.

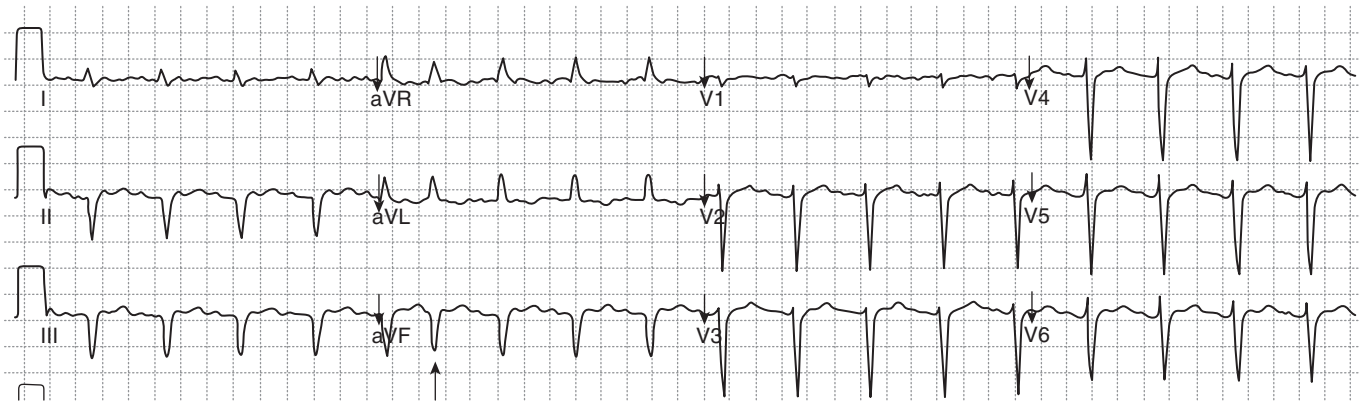

FIG. 2 Clockwise atrial flutter with predominant 2:1 atrioventricular conduction. Note the positive flutter waves in leads II, III, and F, negative in V1 and positive in V6. The overall ventricular rate is slower than in Fig. 1 due to a slow flutter rate of approximately 200 bpm. One beat is conducted 1:1 *(arrow). aVF,* Augmented vector foot; *aVL,* augmented vector left; *aVR,* augmented vector right.

evident. Adenosine may be similarly helpful for diagnostic purposes, allowing the unmasking of the atrial rhythm in the absence of ventricular activity. Maneuvers that affect AV conduction are unlikely to terminate atrial flutter.

- Direct current cardioversion is the treatment of choice for acute management of atrial flutter associated with hemodynamic instability or debilitating symptoms such as angina, congestive heart failure, or hypotension. Electrical cardioversion may be successful with energies as low as 25 joules, but because 100 joules is virtually always successful, this may be a reasonable initial shock strength. If the electrical shock results in atrial fibrillation, a second shock at a higher energy level is used to restore normal sinus rhythm. Sedation of a conscious patient is highly recommended before cardioversion is performed. Patients should be therapeutically anticoagulated for at least a mo or longer depending on their stroke risk (CHA_2DS_2-VASc score; Table 2).
- Overdrive pacing in the atrium may also terminate atrial flutter. This method is especially useful in patients who have recently undergone cardiac surgery and still have temporary atrial pacing wires and in patients who have an implanted pacemaker or defibrillator with an atrial lead.
- Radiofrequency ablation to interrupt the atrial flutter is highly effective for patients with chronic or recurring atrial flutter and is generally considered first-line therapy in those with recurrent episodes of atrial flutter and may be offered for a first-ever episode of atrial flutter. It has been shown to improve health-related quality of life. Despite successful ablation of atrial flutter, however, the risk of future atrial fibrillation remains.

ACUTE Rx

- Treatment choices are based on clinical circumstances. Fig. 3 describes an acute treatment of atrial flutter algorithm. Table 3 summarizes atrial flutter therapy.
- If the patient is unstable, proceed directly to electrical cardioversion.
- In the hemodynamically stable patient, proceed with rate control or rhythm control strategy.
- AV blocking agents such as calcium channel blockers, beta-blockers, and digitalis (second-line treatment) may all be used for rate control. Atrial flutter may spontaneously convert to normal sinus rhythm with this strategy.
- In general, atrial flutter is more difficult to rate-control than atrial fibrillation.
- The rate of recurrence of atrial flutter with cardioversion alone is difficult to determine because most published data combine atrial flutter with atrial fibrillation. However, the recurrence rate is substantial, perhaps 50% at 1 yr.
- Intravenous ibutilide is a first-line medication for pharmacologic cardioversion of atrial flutter in patients with normal systolic function and QT intervals. The success rate is approximately 60%, and it is more effective than procainamide, sotalol, or amiodarone.

CHRONIC Rx

- Few data exist to decide on the choice of rate control versus rhythm control in patients with atrial flutter. However, rate control may be difficult in atrial flutter, and ablation success exceeds 90%. Although ablation results in more durable freedom from atrial flutter recurrence, there are several pharmacologic options to help maintain sinus rhythm after cardioversion of atrial flutter, such as dofetilide, amiodarone, flecainide, propafenone, or sotalol. The choice of antiarrhythmic therapy is, in part, dictated by the presence or absence of underlying structural heart disease.
- Elective outpatient cardioversion or ablation can be performed either immediately preceded by transesophageal echocardiography (TEE) to evaluate the left atrium and the left atrial appendage for thrombus or after a period of at least 3 wk of documented therapeutic anticoagulation before cardioversion. At least 4 wk of anticoagulation should be administered after cardioversion, if not longer, depending on the overall thromboembolic risk of the patient as determined by the CHA_2DS_2-VASc score.

DISPOSITION

More than 85% of patients convert to regular sinus rhythm after cardioversion. Ablation success rates exceed 90%.

REFERRAL

Refer patients who are considered for rhythm control of atrial flutter to cardiologists, especially patients who are candidates for radiofrequency ablation.

TABLE 2 CHA_2DS_2-VASc Risk Score for Prediction of Stroke Risk in Atrial Fibrillation

Risk Factor	Points
CHF/LV dysfunction	1
Hypertension	1
Age ≥75 yr	2
Diabetes mellitus	1
Stroke/TIA/embolism	2
Vascular disease	1
Age 64-74 yr	1
Sex category (female)	1
Maximum score	9

CHF, congestive heart failure; *LV,* left ventricular; *TIA,* transient ischemic attack.

PEARLS & CONSIDERATIONS

COMMENTS

- The surface ECG is the best tool for recognizing atrial flutter and distinguishing atrial flutter from atrial fibrillation.
- Ablation for typical atrial flutter is highly effective, straightforward, and relatively safe. It should be considered for patients with recurrent episodes and even for a first-ever episode.

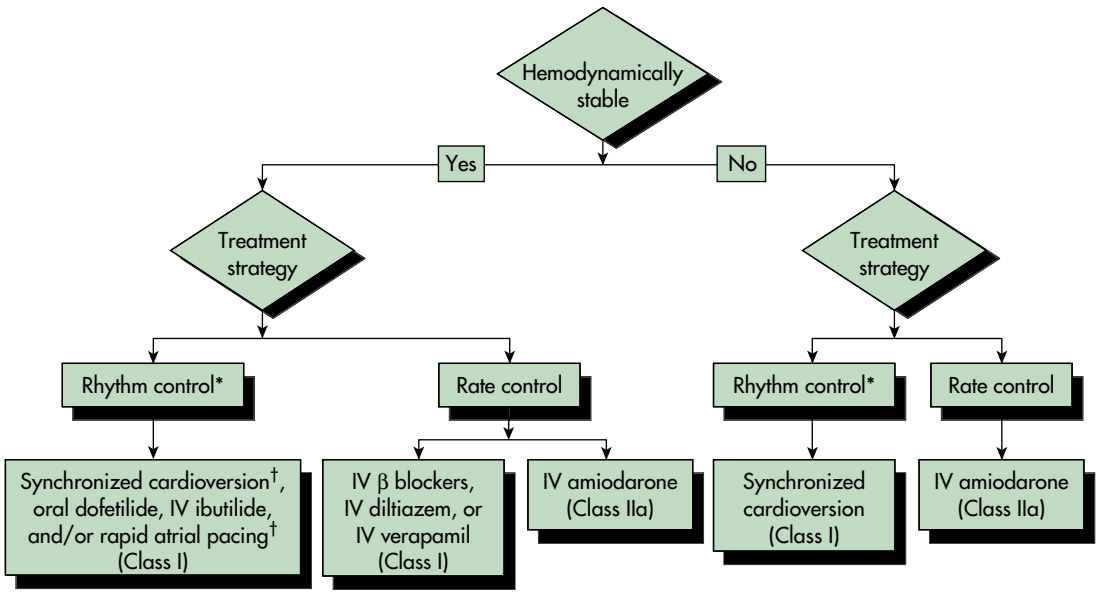

FIG. 3 Acute treatment of atrial flutter. *Anticoagulation as per guideline is mandatory. †For rhythms that break or recur spontaneously, synchronized cardioversion, or rapid atrial pacing is not appropriate. *IV,* Intravenous. (Reproduced with permission from Page RL et al: 2015 ACC/AHA/HRS Guideline for the management of adult patients with supraventricular tachycardia, *JACC* 67(13):e27-e115, 2016. In Olshansky B et al: *Arrhythmia essentials,* ed 2, Philadelphia, 2017, Elsevier.)

TABLE 3 Atrial Flutter Therapy

Acute therapy for poorly tolerated AFL or continuous rapid ventricular rate	• If prolonged (i.e., >48 to 72 hr), anticoagulation with heparin followed by therapeutic warfarin or NOAC as cardioversion may be associated with thromboembolic risk. Anticoagulation guidelines for cardioversion are the same as for atrial fibrillation and may indicate need for a TEE for prolonged episodes. Adenosine and carotid massage can be used to help to diagnose AFL masquerading as sinus rhythm. • **First line:** DCC under anesthesia with anticoagulation as necessary. Consider the length of the episode. • **Second line:** Ibutilide or procainamide may be attempted for conversion prior to DCC attempts. Ibutilide may be 70% effective if AFL has been present for <48 hr, although often this is not known with certainty. Procainamide may help maintain sinus rhythm. • **Alternate:** Rapid atrial pacing (esophageal, epicardial, or endocardial, depending on the situation). To pace terminate, pace for 10 to 15 s at a rate of 10% to 20% faster than rate of flutter. If ineffective, burst pace 10 bpm faster at a time for 10 to 15 s at a time until conversion to AF or sinus rhythm. Adding procainamide may help pace termination efficacy; however, it may speed AV conduction if the ventricular response is not adequately controlled with AV nodal blocker drugs (see Chronic prevention, later); 20% to 30% will pace to AF and 10% to 20% will have no effect from pacing, depending on patient selection for the procedure. When AF occurs, it is usually short lived and terminates spontaneously within 24 hr. If persistent, DCC can be attempted with or without antiarrhythmic drugs. Rapid AFL (atrial rate >350) and atrial fib/flutter usually cannot be pace terminated. However, slower AFL (rate <350) of any flutter wave morphology can often be pace terminated. • Oral drug loading alone to terminate AFL is rarely useful. • If recurrent episodes, use class IC or III antiarrhythmic drugs until steady state is achieved, then attempt cardioversion. These drugs (particularly 1C drugs) may stabilize the flutter circuit. It may also create another form of AFL—"IC" AFL—from AF. Ablation remains first-line therapy, especially if AFL is isthmus dependent. • Consider ablation for all persistent, refractory, or symptomatic AFL. However, despite AFL ablation, AF may occur, especially in individuals with underlying structural heart disease. • AV nodal ablation, although not preferable, could be considered when ventricular rate control cannot be achieved and flutter cannot be ablated, or if symptomatic, refractory, and/or if associated with tachycardia-induced cardiomyopathy. This option may be considered in cases where individuals have multiple forms of nonablatable AFL or AF and especially for those who do have non–isthmus-dependent AFL.
Chronic prevention	• If structural heart disease without CHF: sotalol (initiate in the hospital), dofetilide, amiodarone. • If structural heart disease with CHF: amiodarone, dofetilide. • If no structural heart disease: propafenone, flecainide, sotalol, dofetilide, or amiodarone, but propafenone or flecainide may need concomitant AV nodal blocking drugs to prevent 1:1 conduction. • If class I or III drugs are used, first control the ventricular response rate with an AV nodal blocking drug. Otherwise, the vagolytic effects of class IA drugs can enhance AV nodal conduction, and both 1A and 1C drugs can lead to AFL with 1:1 AV conduction. • Drug therapy alone for pure AFL flutter is usually not effective. • Consider radiofrequency catheter ablation early; it has become first-line therapy.
Nonresponders with severe symptoms	• If type I AFL, radiofrequency ablation of the right atrial isthmus. • Atypical AFL is more difficult to ablate and depends on the location of reentrant circuit. Success rates are lower than that for typical AFL. It is more difficult when there is congenital heart disease, valve disease, or prior surgery in which significant areas of scar are present. • Ventricular rate control, antiarrhythmic drugs, or AV node ablation (less preferable) can be performed for atypical, nonablatable AFL. • If AV node ablation and pacing is performed and AFL is intermittent, mode-switching function should be programmed "ON."
MI	• If hemodynamic intolerance or ongoing refractory myocardial ischemia, emergent cardioversion. AFL may increase MVO_2 due to rapid ventricular rate, causing further ischemia, diastolic dysfunction, and pulmonary congestion and edema. • If recurrent, IV amiodarone or procainamide. • Consider temporary antitachycardia pacing if recurrent and poorly tolerated.
Preoperative	• For cardiac surgery, convert AFL to NSR if adequate anticoagulation has been achieved, or ensure that ventricular response is well controlled. • If surgery is elective and AFL is chronic, antiarrhythmic drugs or catheter ablation may be considered. However, anticoagulation should be continued at least 3 wk after conversion of longer-term (>48 hr) AFL prior to elective surgery. • For more urgent surgery in which anticoagulation cannot be used, consider rate control without cardioversion. • For short-duration (<48 hr) AFL, DCC can be performed (may consider heparin prior to DCC with surgical consultation as to risk).
Postoperative	• AFL occurs in 10%-20% of all patients after cardiac surgery; it typically occurs with AF. Incidence peaks at days 2-3. It is more common in older patients. It rarely occurs after other types of surgery. The AFL may resolve spontaneously; however, the rhythm can increase the length of hospital stay, exacerbate heart failure, slow the recovery process, and cause symptoms. • Control rate with β-adrenergic blocker if no CHF or bronchospastic disease and good LVEF (>40%). Diltiazem is often successful as a second-line drug, but use with caution in patients with poor LVEF. Digoxin for rate control is less effective but may be considered, particularly in patients with poor LV function. • IV amiodarone may be useful for persistent and poorly tolerated AFL; amiodarone or other antiarrhythmic drugs may be helpful for recurrent episodes. • DCC or atrial pace termination (if atrial pacing leads are present) is often successful, especially when employed early after the AFL onset. • Discontinue inotropic drugs, if possible.

From Olshansky B et al: *Arrhythmia essentials,* ed 2, Philadelphia, 2017, Elsevier.

- Patients with atrial flutter carry a significant risk for subsequent development of atrial fibrillation.
- Anticoagulation should be considered for all patients whose CHA_2DS_2-VaSc score is ≥2. Anticoagulation is generally not recommended in patients with a CHA_2DS_2-VaSc score of zero. For patients with a CHA_2DS_2-VaSc score of 1, low-dose aspirin or oral anticoagulants (warfarin, dabigatran, rivaroxaban, apixaban, or edoxaban) are appropriate options.
- Although anticoagulation recommendations for atrial flutter are identical to those for atrial fibrillation, studies suggest that the absolute risk of stroke is lower from atrial flutter than from fibrillation.

TABLE E1 Characteristics of Different Types of Atrial Flutter and Distinguishing Features on Scalar Electrocardiography

Type	Reentrant Circuit	ECG Pattern	Lead V1/V6
Typical counterclockwise	Tricuspid annulus dependent on the CTI	Sawtooth flutter wave; negative in II, III, and aVF	Positive V1 Negative V6
Typical clockwise	Tricuspid annulus dependent on the CTI	"Inverse sawtooth"; positive and often notched in II, III, and aVF	Broad and negative in V1 (often notched) Positive in V6
Lower loop reentry	CTI	Usually similar to typical counterclockwise CTI flutter except subtle loss of terminal positive deflection in leads II, III, and aVF	Usually similar to typical counterclockwise
Upper loop reentry	Superior vena cava and upper crista terminalis	Similar to typical clockwise flutter	Similar to typical clockwise flutter
Right atrial free wall	Around areas of scar in lateral or posterior right atrium (caused by previous atrial surgery or spontaneously)	Variable	Typically negative or biphasic with terminal negative deflection in V1
Septal atrial flutter	Atrial septum, typically after previous surgery	Variable	Usually biphasic or isoelectric in V1
Mitral annular flutter	Around mitral annulus, often slow zone of block around PV interval; frequently occurs in setting of left atrial surgery or ablation	Variable; I, III, and aVF, often positive but low amplitude	Usually positive in V1 (or rarely isoelectric) and often broad
Postatrial fibrillation ablation/maze flutter	Variable; circuit involves previous ablations or scar in left atrium	Variable	Variable

aVF, Augmented vector foot; *CTI,* cavotricuspid isthmus.

BASIC INFORMATION

DEFINITION

Atrial myxoma is a benign neoplasm of mesenchymal origin and is the most common primary tumor of the heart.

SYNONYM

Cardiac myxoma

ICD-10CM CODE
D15.1 Benign neoplasm of heart

EPIDEMIOLOGY & DEMOGRAPHICS

- Primary cardiac tumors are extremely rare, with an autopsy frequency of 0.001% to 0.3%. The most frequent cardiac tumors are metastases, occurring 30 times more frequently than primary tumors.
- Myxomas are the most common primary cardiac tumors, accounting for 30% to 50% of all benign neoplasms of the heart.
- 65% of cardiac myxomas occur in females. 4.5% to 10% of cardiac myxomas are familial (Carney syndrome).
- Median age of incidence is 49 yr but can occur at any age.
- Average age of incidence of familial cases is 25 yr.
- Most arise in the left atrium (75%), but myxomas can also be found in the right atrium (18%), right ventricle (4%), and left ventricle (3%). They are usually pedunculated and attached to the intraatrial septum (Fig. E1).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with atrial myxomas, when symptomatic, characteristically present in one of three ways:

1. Atrioventricular valve obstruction (e.g., mitral or tricuspid valve): May present with dyspnea, orthopnea, paroxysmal nocturnal dyspnea, wheezing, edema, dizziness, syncope, chest pain, atrial fibrillation, and sudden death (rare). A marked change in the severity of any symptom caused by a change in position of the patient, especially if recumbency relieves dyspnea, is suggestive of myxoma.
2. Systemic embolization: Leading to cerebrovascular accidents, pulmonary embolism, paradoxical embolism and acute coronary syndrome. This is present in 29% of patients with atrial myxomas.
3. Constitutional symptoms: Fever, weight loss, arthralgias, and Raynaud phenomenon.
4. Other rare manifestations include peripheral neuropathy, typical angina caused by coronary steal phenomenon (especially large vascularized atrial myxomas), and paraneoplastic syndromes.

- On exam there may be widely split loud S1, secondary pulmonary hypertension, murmurs of regurgitation (holosystolic) or stenosis (rumbles), an early diastolic sound 80 to 120 milliseconds after A2 called "tumor plop" which may resemble an opening snap.

ETIOLOGY:

- Most cases (90%) of atrial myxomas are sporadic with no known cause.
- Carney complex, transmitted in an autosomal dominant pattern, accounts for the majority of familial myxomas and as much as 7% of cardiac myxomas. Carney syndrome manifests as cardiac and extracardiac myxomas, pigmented skin discoloration, endocrine hyperactivity, and other tumors, such as schwannomas. There are at least three different genetic loci with two identified genes for this complex.

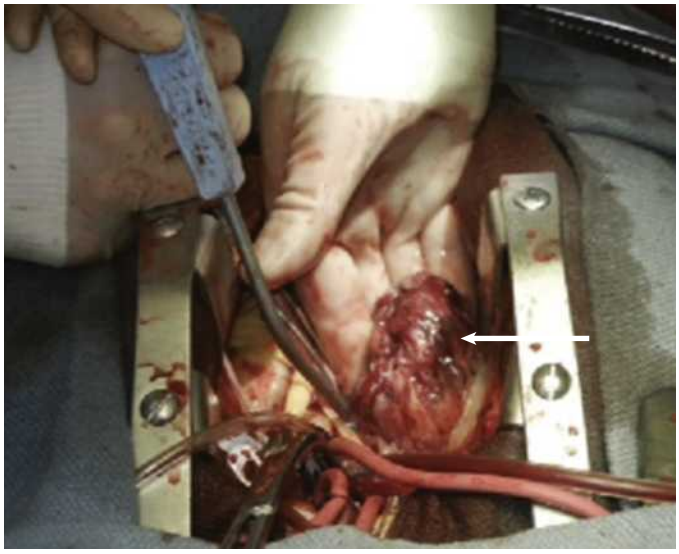

FIG. E1 Gross appearance of a left atrial myxoma. Note the thrombus-appearing material on the surface *(arrow),* which is likely a mechanism for embolic events associated with cardiac myxomas. (From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine*, ed 11, Philadelphia, 2019, Elsevier.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary valvular diseases: Mitral stenosis, mitral regurgitation, tricuspid stenosis, tricuspid regurgitation
- Pulmonary hypertension
- Endocarditis
- Vasculitis
- Atrial thrombus (Table E1 summarizes distinguishing characteristics of thrombus from atrial myxoma.)
- Pulmonary embolism
- Cerebrovascular accidents
- Collagen-vascular disease
- Carcinoid heart disease
- Benign tumors of the heart (papillary fibroelastoma, rhabdomyoma, fibroma, teratoma, and lipoma)
- Malignant tumors of the heart (angiosarcoma, rhabdosarcoma, fibrosarcoma, and leiomyosarcoma)
- Metastatic tumors to the heart (melanoma, lung, breast, renal, esophageal, and sarcomas)

WORKUP

A high index of suspicion is needed because the clinical manifestations are nonspecific and similar to many common cardiovascular and pulmonary diseases.

LABORATORY TESTS

Although not very specific, the following laboratory findings may be abnormal in patients with atrial myxomas:

- Complete blood count: Anemia, polycythemia, thrombocytopenia may occur
- Erythrocyte sedimentation rate, C-reactive protein, and serum immunoglobulins are commonly elevated
- Cardiac biomarker levels (troponin and CK-MB) can be elevated
- Electrocardiogram: Nonspecific findings including left or right atrial enlargement, atrial fibrillation, premature ventricular depolarizations, or ventricular tachycardia

IMAGING STUDIES (Fig. E2)

- Transthoracic echocardiography (Fig. E3): With 95% diagnostic sensitivity, it is the initial test of choice in suspected cases of atrial myxoma.
- Chest radiograph: About one third of patients have normal findings. Evidence of altered cardiac contour, pulmonary edema, and chamber enlargement may be present.
- Transesophageal echocardiography: Nearly 100% sensitive and may better define cardiac masses not clearly visualized by transthoracic echocardiography.
- CT: Often used for diagnosis; defines tumor extension and evaluates adjacent cardiac structures.
- MRI (Fig. E3): Delineates size, shape, and tissue characteristics, helping distinguish thrombus from tumor.

TABLE E1 Distinguishing Thrombus from an Atrial Myxoma

	Myxoma	Thrombus
Contrast enhancement	Yes	No
Morphology	Sessile or pedunculated	Usually sessile
Atrial fibrillation	Uncommon	Likely to be present
Atrial location	Commonly attached to the intraatrial septum	Usually occurs in an enlarged chamber and the atrial appendage is commonly involved

From Grant LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, Philadelphia, 2019, Elsevier.

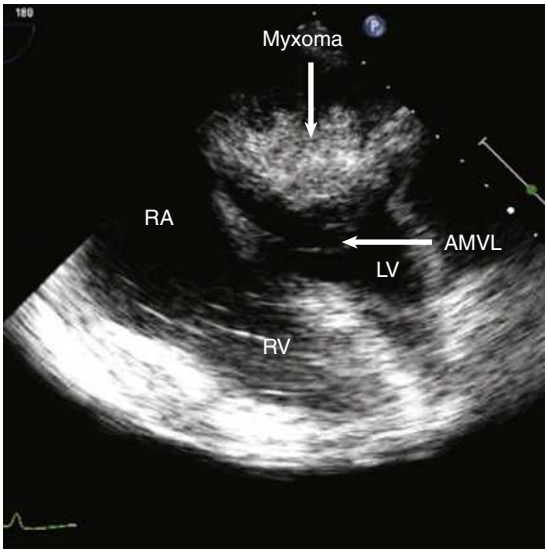

FIG. E2 A large left atrial myxoma prolapsing across the mitral valve, resulting in heart failure symptoms. *AMVL,* Anterior mitral valve leaflet; *LV,* left ventricle; *RA,* right atrium; *RV,* right ventricle. (From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine*, ed 11, Philadelphia, 2019, Elsevier.)

- Cardiac catheterization: Will show neovascularization in 50% of the cases and may be required to rule out concomitant coronary artery disease in anticipation of surgical excision.

Rx TREATMENT

ACUTE GENERAL THERAPY

- Surgical excision is the treatment of choice.
- Surgery should be done promptly because systemic embolization and/or sudden death can occur while waiting for the procedure.

CHRONIC Rx

Postoperative arrhythmias and conduction abnormalities were present in 26% of patients and can be treated accordingly.

DISPOSITION

- Surgical results have reported a 95% survival rate after a follow-up of 3 yr.
- Careful follow-up is necessary because up to 5% of sporadic cases and 20% of familial cases of atrial myxoma may recur within the first 6 yr after surgery. A family history of myxomas, atypical location and multicentric features are risk factors for myxoma recurrence after resection.
- Sudden death in untreated patients may occur in up to 15%, resulting from coronary or systemic embolization or obstruction of the mitral or tricuspid valve.

REFERRAL

- Consultation with a cardiologist is recommended.
- Once the presence of cardiac tumor is confirmed, consultation with a cardiovascular surgeon is needed for prompt surgical excision.

! PEARLS & CONSIDERATIONS

- Approximately two thirds of patients present with cardiovascular symptoms, specifically dyspnea, often suggestive of valvular obstruction.
- Nearly one third of patients have evidence of systemic embolization.

COMMENTS

Annual echocardiograms should be performed to monitor for recurrence of atrial myxomas after surgical excision.

BASIC INFORMATION

DEFINITION

An atrial septal defect (ASD) is a true defect in the interatrial septum that allows blood flow between the atria. Fig. 1 illustrates the physiology of ASD. The five forms of ASD are described below and illustrated in Fig. 2.

- Primum: This type of ASD occurs when the anterior and posterior endocardial cushions do not fuse with the septum primum creating a deficiency in the inferior portion of the septum primum. This defect is frequently associated with a cleft anterior mitral leaflet and with left ventricular outflow obstruction.
- Secundum: This is the most common form of ASD. It is caused by failure of the septum primum to fuse with the septum secundum. This defect can form anywhere along the septum, but it is most commonly found near the fossa ovalis.
- Sinus venosus defect: This defect is located at the junction of the right atrium and the superior vena cava or inferior vena cava. In a sinus venosus defect, a left-to-right shunt develops through an opening in the wall between the pulmonary veins and the right atrium. Most commonly this defect involves an anterior wall deficiency in the right upper pulmonary vein, which allows it to drain into the right atrium while remaining anatomically connected to the left atrium. Less commonly, the right lower pulmonary vein is involved. The left pulmonary veins can also drain into a vertical vein that communicates with the superior vena cava.
- Coronary sinus septal defect (unroofed coronary sinus): This is a defect between the wall of the coronary sinus and the left atrium that results in a left-to-right shunt. This defect is often associated with a persistent left superior vena cava.
- Iatrogenic atrial septal defect (iASD) is a complication of electrophysiology and structural interventional procedures that require transseptal puncture.

ASD should be distinguished from a patent foramen ovale (PFO), a flaplike opening between the two atria, caused by failure of the septum primum to fuse to the superior limb of the septum secundum in postnatal life. Whereas ASDs represent a congenital defect established in utero due to failure of normal atrial septal development, a persistent PFO in postnatal life represents the failure of an anatomically necessary defect to close. PFO occurs in approximately 20% to 25% of the normal adult population.

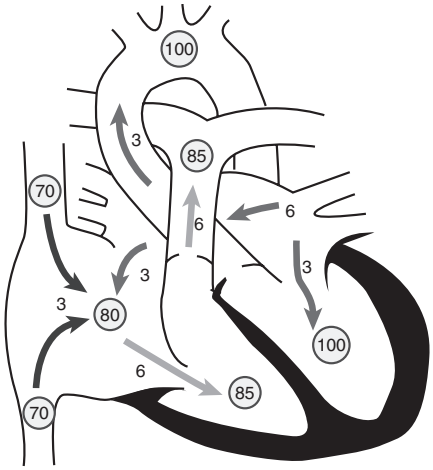

FIG. 1 Physiology of atrial septal defect (ASD). Circled numbers represent oxygen saturation values. The numbers next to the arrows represent volumes of blood flow (in L/min/m^2). This illustration shows a hypothetical patient with a pulmonary-to-systemic blood flow ratio (Qp/Qs) of 2:1. Desaturated blood enters the right atrium from the venae cavae at a volume of 3 L/min/m^2 and mixes with an additional 3 L of fully saturated blood shunting left to right across the ASD; the result is an increase in oxygen saturation in the right atrium. Six liters of blood flow through the tricuspid valve causing a mid-diastolic flow rumble. Oxygen saturation may be slightly higher in the RV because of incomplete mixing at the atrial level. The full 6 L of blood flows across the RV outflow tract and causes a systolic ejection flow murmur. Six liters return to the left atrium, with 3 L shunting left to right across the defect and 3 L crossing the mitral valve to be ejected by the left ventricle into the ascending aorta (normal cardiac output). (From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.)

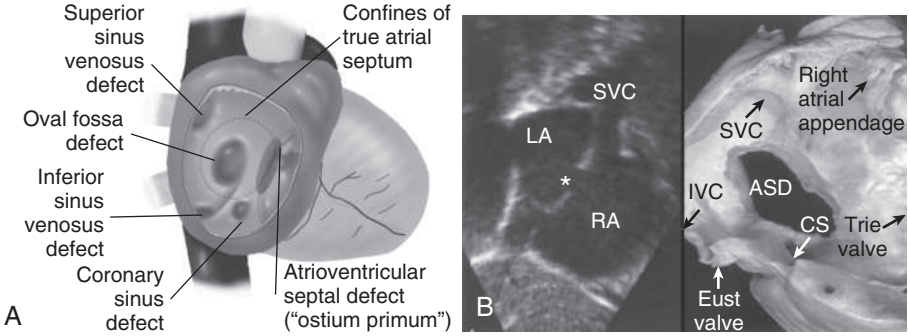

FIG. 2 A, Schematic diagram outlining the different types of interatrial shunting that can be encountered. Note that only the central defect is suitable for device closure. **B,** Subcostal right anterior oblique view of a secundum atrial septal defect *(ASD) (asterisk)* that is suitable for device closure. The right panel is a specimen as seen in a similar view, outlining the landmarks of defect. *CS,* Coronary sinus; *IVC,* inferior vena cava; *LA,* left atrium; *RA,* right atrium; *SVC,* superior vena cava. (From Zipes DP et al [eds]: *Braunwald's heart disease*, ed 7, Philadelphia, 2005, Saunders.)

SYNONYMS

ASD
Interatrial septal defect

ICD-10CM CODES

Q21.1	Atrial septal defect
I23.1	Atrial septal defect as current complication following acute myocardial infarction

EPIDEMIOLOGY & DEMOGRAPHICS

- Secundum, 75%; primum, 15% to 20%; sinus venosus, 5% to 10%; coronary sinus, <1%
- Incidence of ASD is greater in females and in patients with Down syndrome
- Accounts for 8% to 10% of congenital heart abnormalities
- Prevalence is 1.6 per 1000 live births
- Holt-Oram syndrome is an autosomal dominant disorder that involves skeletal anomalies, ASD, and cardiac conduction disease (most commonly atrioventricular [AV] blocks)
- Secundum defects are associated with multiple genetic syndromes including Noonan syndrome, Treacher Collins syndrome, thrombocytopenia–absent radii syndrome, and Down syndrome (trisomy 21)
- ASD may occur as an isolated defect or as part of other congenital cardiac syndromes such as Ebstein anomaly, Lutembacher syndrome, or fetal alcohol syndrome

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Small ASDs or PFOs may close spontaneously during infancy whereas infants with large ASDs may develop heart failure, recurrent respiratory infections, or failure to thrive. The majority of ASDs are small and do not cause any symptoms during infancy. Patients with small ASDs are usually diagnosed by the presence of a cardiac murmur auscultated during routine physical examination.
- Exertional fatigue and dyspnea are usually the main presenting symptoms.

- On rare occasions, young adults may present with ischemic stroke caused by paradoxical embolism through the ASD or PFO.
- Platypnea-orthodeoxia (characterized by dyspnea and deoxygenation when changing from a recumbent position to sitting or standing).
- Patients with ASDs caused by congenital syndromes may present with clinical features to the underlying syndrome.
- Atrial arrhythmias such as atrial fibrillation and atrial flutter are significantly increased in patients with ASDs.

CLINICAL FEATURES

- Cyanosis and clubbing (due to right-to-left shunting)
- Increased jugular venous pressure (may be due to RV failure from left-to-right shunting through a small ASD, or elevated left atrial pressures when a large ASD is present)
- Prominent RV impulse
- Visible and palpable pulmonary artery pulsations
- Wide fixed splitting of S_2
- An accentuated pulmonic component of S_2 (if the patient has pulmonary hypertension)
- Pansystolic murmur best heard at the apex (secondary to mitral regurgitation associated with the ostium primum defect)
- Ejection systolic flow murmur (pulmonary valve flow murmur; Fig. E3)
- Diastolic rumble (atrioventricular valve flow murmur)

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary pulmonary hypertension
- Pulmonary stenosis
- Rheumatic heart disease
- Mitral valve prolapse
- Cor pulmonale
- Anomalous pulmonary venous connection

WORKUP

- ECG:
  1. Ostium primum defect: Extreme left axis deviation, incomplete or total right bundle branch block, prolongation of PR interval
  2. Sinus venosus defect: Right axis deviation, abnormal P axis (suggesting an absent or deficient sinus node)
  3. Ostium secundum defect: Right axis deviation, incomplete or total right bundle branch block, right atrial enlargement

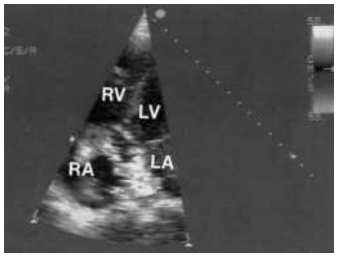

FIG. 4 Color flow Doppler apical four-chamber view showing blood flow from the left atrium *(LA)* to the right atrium *(RA)* through a moderately sized atrial septal defect. *LV,* Left ventricle; *RV,* right ventricle. (From Zipes DP: *Braunwald's heart disease: a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.)

IMAGING STUDIES

- Chest x-ray: Cardiomegaly, right heart enlargement, increased pulmonary vascular pattern.
- Echocardiography (Fig. 4): Transthoracic echocardiography (TTE) has a high degree of sensitivity for diagnosing secundum and primum ASDs. Echocardiography with saline bubble contrast and Doppler flow studies can measure the size of the defect, the direction of shunting, right heart volume overload, and elevated pulmonary artery pressures. However, sinus venosus defects are frequently missed.
- Transesophageal echocardiography (TEE): TEE is much more sensitive than TTE in identifying and locating pulmonary venous return in sinus venosus defects and can be helpful identifying all forms of ASD when TTE is nondiagnostic. TEE can determine defect size, defect proximity to other cardiac structures, and the size of the defect rims. Measurements generated by TEE are used in the catheterization laboratory to determine whether a patient is suitable for device closure.
- Cardiac catheterization: Left heart catheterization is not used to diagnose ASDs; it is used to assess the coronary arteries before ASD repair. Right-sided heart catheterization is used to assess the severity of the shunt, the extent of pulmonary hypertension, pulmonary vascular resistance (PVR), and pulmonary artery vasoreactivity to vasodilators. In ASD, right-sided heart catheterization will often reveal a "step-up" in arterial oxygen saturation in the right atrium compared with the superior vena cava due to left-to-right shunting from primum or secundum defects. This may not be the case in patients with ASDs from sinus venous defects who develop only partial anomalous pulmonary venous return.
- Cardiac MRI and CT: MRI is the gold standard for assessing RV size and function. MRI is also useful for assessing anomalous pulmonary venous return and persistent left superior vena cava. Cardiac CT can offer similar information. This imaging is useful when echocardiography is not diagnostic.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Asymptomatic patients with small defects, shunts with a pulmonary to systemic flow ratio (Qp/Qs) of <1.5:1, normal RV size, and without pulmonary artery hypertension (PAH) do not require medical therapy. However, they should be routinely assessed for development of clinical symptoms, arrhythmias, embolic events, and progression of structural disease with serial echocardiography.
- Patients should undergo echocardiography every 2 to 3 yr to monitor RV size and function and pulmonary pressure. Left-to-right shunting is expected to increase with age due to progressive noncompliance of the left ventricle and age-acquired heart disease.

GENERAL Rx

- Children and infants: ASD closure is indicated before age 10 if Qp/Qs is >2:1 (many experts advocate closure for Qp/Qs >1.5:1), if ASD size is >5 mm, or if there is evidence of RV dilation.
  1. ASDs with a diameter of <5 mm and no evidence of RV volume overload do not require closure unless associated with paradoxic embolism.
  2. ASD closure (either percutaneously or surgically) is indicated for either right atrial or right ventricular enlargement even if the patient is asymptomatic.
  3. Sinus venosus, coronary sinus, or primum variant ASDs should be repaired surgically rather than by percutaneous closure.
  4. Surgical closure of a secundum variant ASD is appropriate when other defects exist that require surgical intervention, or when the anatomy of the defect precludes the use of a percutaneous device.
- Adults: ASD closure should be considered if any of the following are present: Left-to-right shunting with Qp/Qs >1.5:1, right-sided chamber enlargement, clinical symptoms, pulmonary hypertension with pulmonary artery pressure less than two-thirds systemic levels, PVR less than two-thirds systemic vascular resistance, or pulmonary hypertension that responds to vasodilation therapy. These patients should be managed by specialists in adult congenital heart disease and pulmonary hypertension.
- Patients with severe, irreversible PAH and no evidence of a left-to-right shunt should not undergo ASD closure.
- ASD closure is reasonable in the presence of:
  1. Paradoxic embolism (Class 2a indication).
  2. Documented orthodeoxia-platypnea (Class 2a indication).
- The majority of iASDs close spontaneously. However, ASD closure should be actively pursued if high risk features are present such as iASD >8 mm, right-to-left shunting, large left-to-right shunt, a predisposition to thromboembolism, or right ventricular dysfunction.
- Percutaneous catheter device closure has >95% success rate in appropriate candidates. Early complications include device thrombus formation, atrial arrhythmias, erosion, and device dislodgement. Potential mid- and long-term complications include late device erosion into the aortic root or pericardium, atrial dysrhythmias, and infective endocarditis. A combination of low-dose aspirin and clopidogrel is required for 3 to 6 mo after the procedure to prevent thrombus formation. Close clinical follow-up that includes echocardiogram is recommended before discharge, then at 1 wk, 6 mo, and 12 mo postintervention.

- Percutaneous closure is contraindicated in patients with sinus venosus, primum, or unroofed coronary sinus variant ASDs. Successful percutaneous ASD closure in patients with secundum defects depends on the anatomy of the defect. Percutaneous closure is not indicated for secundum defects if the defect is too large; too close to the coronary sinus, AV valves, or pulmonary veins; or if there are inadequate rims. Percutaneous closure of secundum ASD may be successful if the stretched diameter is <41 mm with adequate rims. The procedure should not be performed in the presence of sepsis, bleeding disorder, or intracardiac thrombi.
- Surgical closure involves the placement of a pericardial or Dacron patch through a minimally invasive approach (with or without robotic assistance). Surgical closure of ASD improves function status, exercise capacity, and patient survival; however, it does not prevent atrial fibrillation or stroke, especially if patients pursue ASD repair after age 40.
- Cox maze procedure should be considered for patients with intermittent or chronic atrial fibrillation when they undergo ASD closure.

DISPOSITION

- Mortality rate increases in patients with large ASDs that go untreated. Complications of longstanding ASD include RV failure, arrhythmias, paradoxic embolism, and PAH leading to right-to-left shunting (Eisenmenger syndrome).
- Patients with small shunts (<1.5:1) have a normal life expectancy.
- Spontaneous closure or size reduction is more likely in younger patients with defects <10 mm in diameter.
- A basic assessment for adults with congenital heart disease should include systemic arterial oximetry, ECG, chest radiograph, transthoracic echocardiography, and blood tests for complete blood count and coagulation screen.
- Intracardiac shunts constitute moderate risk for noncardiac procedures. High-risk features include severe systolic dysfunction (ejection fraction <35%), severe pulmonary hypertension, cyanotic heart disease, and severe left-side outlet obstruction.
- Annual postoperative clinical follow-up is recommended for patients who pursue ASD repair as adults in order to monitor for PAH, atrial arrhythmias, RV or LV dysfunction, and coexisting valvular lesions.
- Preoperative atrial fibrillation is a risk factor for both postoperative and long-term atrial fibrillation. The older the patient undergoing ASD repair, the more likely that patient is to develop atrial fibrillation, even after the ASD is repaired.
  1. The benefits of ASD repair include improved functional status and exercise capacity, improved survival (if closed in childhood), improved quality of life, prevention of right-sided heart failure, and prevention of PAH.
  2. Potential mid- to long-term complications of ASD closure in adulthood include tachyarrhythmias (atrial fibrillation or atrial flutter), bradyarrhythmias (sinus node dysfunction or heart block), stroke (greater risk in older patients), residual ASDs (due to incomplete initial closure or patch dehiscence), right-sided heart failure, PAH (risk is correlated with the size of the original defect and inversely related to age at time of closure), mitral valve regurgitation or subaortic stenosis (associated with primum ASDs), device migration/erosion, and pulmonary venous congestion.
  3. Women with ASD have an increased risk of paradoxic embolus, stroke, arrhythmia, and heart failure during pregnancy. ASD repair before pregnancy reduces these risks. However, if ASD is undiagnosed before pregnancy, close monitoring for the duration of pregnancy is sufficient. The only contraindication to pregnancy in women with ASD is severe PAH.
  4. Scuba diving is contraindicated in patients with unrepaired ASDs because the pressure from deep sea diving increases the risk of paradoxic emboli. In addition, high-altitude climbing should be avoided because it can lead to right-to-left shunting and oxygen desaturation.
- In regard to infective endocarditis prophylaxis for dental procedures:
  1. Prophylaxis is not indicated for an unrepaired ASD.
  2. Prophylaxis is indicated for 6 mo following ASD repair if prosthetic material was used to repair the defect.
  3. Prophylaxis is indicated for a repaired ASD (or any congenital heart defect) if residual defects remain either at or near the site of the prosthetic material or device used for repair.

The estrogen-containing oral contraceptive pill is not recommended in acute congenital heart disease patients at risk for thromboembolism. This includes patients with atrial fibrillation, severe PAH, Fontan repair, or cyanosis related to an intracardiac shunt.

Atrioventricular Dissociation

BASIC INFORMATION

DEFINITION

Atrioventricular (AV) dissociation is defined as a lack of association between the atria and the ventricles or independent function of the atria and ventricles. This simple definition will serve as a reminder that AV dissociation should be considered an umbrella rather than a diagnosis. AV dissociation may occur in the setting of bradycardic rhythms (Fig. E1 and Fig. E2), complete heart block (Fig. E3), as well as tachycardic rhythms (ventricular tachycardia, atrial rhythm with associated accelerated junctional rhythm or AV nodal reentrant tachycardia).

SYNONYMS

Third-degree AV block
CHB
Complete AV block

ICD-10CM CODE

I44.2 Atrioventricular block, complete

EPIDEMIOLOGY & DEMOGRAPHICS

The prevalence is the sum of the diagnoses that are characterized by AV dissociation.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Physical examination findings may be normal unless the arrhythmia is causing hemodynamic compromise. If the right atrium contracts against a closed tricuspid valve during ventricular systole, Cannon A waves may be seen in the jugular vein. Patients may present with the following clinical manifestations:

- Dizziness, palpitations
- Syncope or presyncope (caused by reduced cardiac output)
- Fatigue, impaired exercise tolerance
- Mental status changes
- Congestive heart failure
- Angina pectoris
- Some patients may be asymptomatic

ETIOLOGY

- Slow rate of firing from sinus node
- Inappropriately fast pacemaker from the ventricle
- Iatrogenic: Anesthesia, inotrope infusion, ventricular pacing, radiofrequency ablation of slow pathway, digoxin toxicity
- Sinus node disease, ischemia, hyperkalemia, overactive vagal drive
- Complete heart block: Progressive fibrosis of the His-Purkinje system, medications, Lyme disease

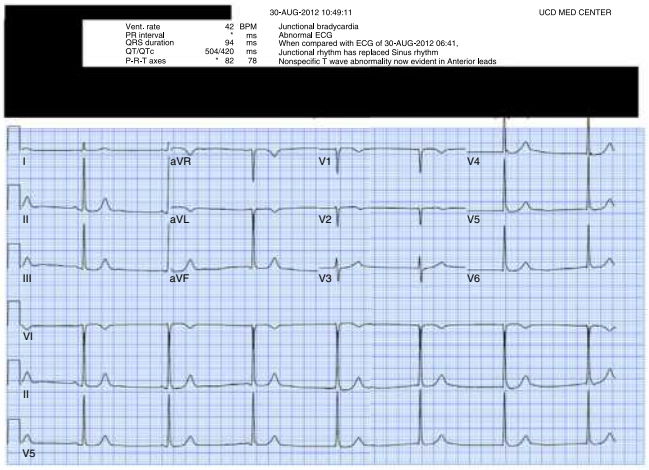

FIG. E1 An electrocardiogram was obtained at the primary care practitioner's office. Computer interpretation indicated junctional bradycardia at a rate of 42 beats per min. While the rate was regular, not every QRS complex was preceded by a P wave. There were no acute ST- or T-wave changes consistent with ischemia. (From Singh GD et al: Food for thought: atrioventricular dissociation, *Am J Med* 126(12):1050-1053, 2013.)

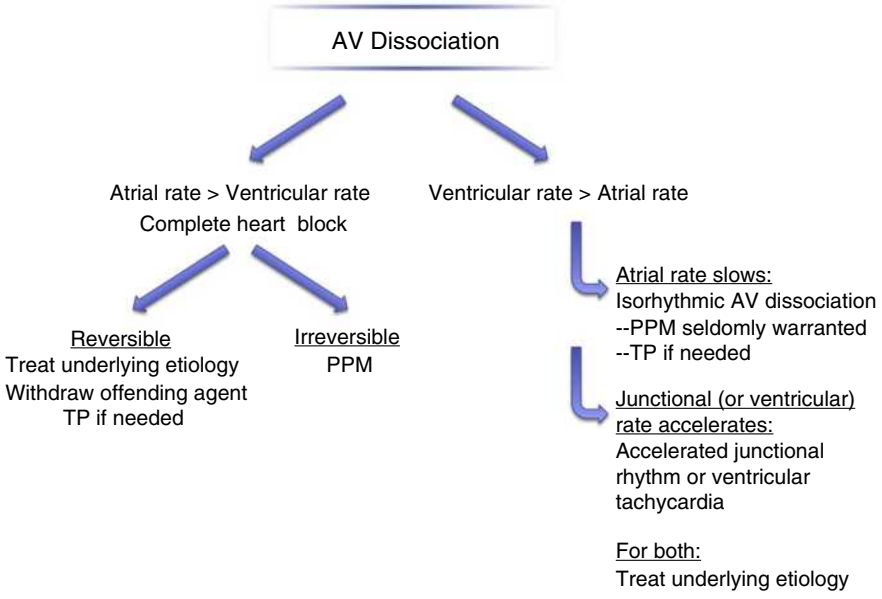

FIG. E2 This flow chart demonstrates the relationship between atrioventricular dissociation due to complete heart block vs. atrioventricular dissociation from a ventricular rate that is greater than the atrial rate. *AV*, atrioventricular; *PPM*, permanent pacemaker; *TP*, temporary pacemaker. (From Singh GD et al: Food for thought: atrioventricular dissociation, *Am J Med* 126(12):1050-1053, 2013.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- The differential diagnosis should be targeted toward the diagnoses that include AV dissociation.
- NOTE: The atrium does not need to be faster than the ventricular rate in AV dissociation, as is the case in the definition of complete heart block.
  1. Isorhythmic AV dissociation: Atrial and ventricular rates are the same but dissociated.
  2. Interference dissociation: Similar atrial and ventricular rates but conduction occurs sometimes.

WORKUP

- Workup such as routine laboratory studies, cardiac biomarkers, and cardiac imaging should be dictated by the clinical circumstances.
  1. Laboratory studies: Particular attention to electrolyte abnormalities (potassium) and digoxin level
  2. Lyme antibody titer in the case of complete heart block, particularly in the Northeastern U.S.

TREATMENT

ACUTE GENERAL Rx

- Initial treatment should focus on the hemodynamic stability and symptoms of the patient.
- Bradycardic rhythms:
  1. If necessary (i.e., symptoms or hemodynamic compromise), a temporary pacemaker is the most reliable therapy.
  2. Hold AV-nodal blocking agents.
  3. Chronotropic medications: Atropine, dopamine, dobutamine, or isoproterenol may be used as second-line agents while preparing for a temporary pacemaker.

FIG. E3 A, In the initial rhythm strip—also shown in Fig. E1—solid black arrows indicate atrial complexes initiated by the sinus node. Note that for each beat, the sinus impulse is progressively closer to the QRS complex, then becomes obscured within the QRS complex, and finally is seen beginning to emerge on the downstroke of the R wave in the last three QRS complexes. The junctional pacemaker, at 42 beats per min, is slightly faster than the atrial rate of 41 beats per min. **B,** Another echocardiogram was performed after the patient was treated for dyspepsia. The rhythm strip shows sinus bradycardia with a rate of 45 beats per min. (From Singh GD et al: Food for thought: atrioventricular dissociation, *Am J Med* 126(12):1050-1053, 2013.)

- Tachycardic rhythms (ventricular tachycardia):
  1. In the setting of hemodynamic compromise, cardioversion is the first-line therapy
  2. IV antiarrhythmic drugs: Amiodarone or lidocaine to suppress the arrhythmia
  3. Treatment of the underlying cause of ventricular tachycardia: Coronary angiogram if ischemia vs. electrophysiology (EP) study +/– ablation

REFERRAL

All patients with AV dissociation should be referred to a cardiologist for diagnostic evaluation of the rhythm.

PEARLS & CONSIDERATIONS

COMMENTS

- Recall that AV dissociation is merely an umbrella that includes multiple diagnoses, including both bradycardic and tachycardic arrhythmias.
- Specific considerations regarding etiology, treatment, and disposition should be directed toward the rhythm that has caused AV dissociation.

AUTHOR: **Aleem I. Mughal, MD**

Attention Deficit Hyperactivity Disorder PTG

BASIC INFORMATION

DEFINITION

Attention deficit hyperactivity disorder (ADHD) is a chronic disorder of attention and/or hyperactivity-impulsivity. Symptoms must be present before 12 yr of age, last at least 6 mo, and cause functional impairment in multiple settings. The diagnostic keys for ADHD are described in Table 1.

SYNONYMS

Hyperactivity
Hyperkinetic disorder
Attention deficit disorder (ADD)
ADHD

ICD-10CM CODES

F90.0	Attention-deficit hyperactivity disorder, predominantly inattentive type
F90.1	Attention-deficit hyperactivity disorder, predominantly hyperactive type
F90.2	Attention-deficit hyperactivity disorder, combined type
F90.8	Attention-deficit hyperactivity disorder, other type
F90.9	Attention-deficit hyperactivity disorder, unspecified type

DSM-5 CODES
314.00, 314.01

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: Diagnosis is usually first made in school-aged children (6 to 9 yr).
PREVALENCE: Five percent to 10% of school-aged children (most prevalent neurodevelopmental disorder among children); up to 5% of adolescents and 2% to 4% of adults. Children from families with low socioeconomic status and children with public insurance are diagnosed with ADHD at higher rates than their peers.
PREDOMINANT SEX: Among children, male predominance with ratio of 2:1 to 4:1. Among adults, ratio is closer to 1:1 (sex difference may reflect referral bias).
PREDOMINANT AGE: Some symptoms must occur before age 12 yr. Symptoms (especially motoric hyperactivity) tend to diminish with age. Up to 70% continue to meet criteria in adolescence, and an estimated 40% to 65% have some symptoms in adulthood.
GENETICS: Strong polygenetic component. First-degree relatives of ADHD patients have 5 times greater risk of ADHD relative to controls. Studies suggest potential involvement of several genes, including those associated with serotonin and glutamate transporters as well as dopamine metabolism in addition to neuronal development.
RISK FACTORS: Possible risk factors include in utero tobacco/drug exposure or hypoxia, low birth weight, prematurity, pregnancy, lead exposure (though most children with elevated lead levels do not develop ADHD), head trauma in young children, family dysfunction, low socioeconomic status. Evidence supports possible association between dietary factors (e.g., refined sugar, food additives) and ADHD in a small percentage of patients. A causal link between environmental toxins and ADHD has not been clearly established.

TABLE 1 Diagnostic Keys for Attention Deficit Hyperactivity Disorder

1. Inattention
   a. Careless mistakes in schoolwork, work, or other activities
   b. Seems not to listen when spoken to directly
   c. Poor follow-through on schoolwork or chores
   d. Difficulty organizing
   e. Easily distracted by extraneous stimuli and is forgetful
2. Hyperactivity
   a. Trouble sitting still
   b. May act as if "driven by a motor"
   c. May talk excessively
3. Impulsivity
   a. Trouble holding back in class
   b. Trouble taking turns
   c. Interrupts

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Three types:
  1. Predominantly inattentive: Difficulty organizing, planning, remembering, concentrating, starting/completing tasks; symptoms may not be present during preferred activities.
  2. Predominantly hyperactive-impulsive: Edgy/restless, talkative, disruptive/intrusive, disinhibited, impatient.
  3. Combined.
- Usually diagnosed in elementary school when achievement is compromised and behavioral problems are not tolerated. Children with academic underproductivity, problems with peer and family relations, or discipline issues are often referred for evaluation. Of the more than 4 million children in the U.S. who have ADHD, most have comorbid conditions (see the following) and nearly half use special education and mental health services.
- Up to 50% may have associated disorders such as psychiatric diagnoses (oppositional defiant disorder, conduct disorder, depression, anxiety, eating disorders), learning disabilities, or substance abuse.
- In adults, motoric hyperactivity is less common, but restlessness, edginess, and difficulty relaxing are often seen. Disorganization and difficulty completing tasks are other common complaints.

ETIOLOGY

Strongest evidence exists for genetic inheritance. Other theories include abnormal metabolism of brain catecholamines, structural brain abnormalities, reduced activation in the basal ganglia and anterior frontal lobe, as well as environmental factors (see earlier).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Medical: Visual/hearing impairment, seizure disorder, head injury, sleep disorder, medication interactions, mental retardation/intellectual disability, specific learning disorder, autism spectrum disorder/development delay, thyroid abnormalities, lead toxicity, movement disorders.
- Psychiatric: Depression, bipolar disorder, disruptive mood, dysregulation disorder, anxiety, obsessive-compulsive disorder, oppositional defiant disorder, intermittent explosive disorder, conduct disorder, posttraumatic stress disorder, reactive attachment disorder, and substance abuse.
- Psychosocial: Mismatch of learning environment with ability, family dysfunction, abuse/neglect.

WORKUP

- Clinical interview should include assessment of symptoms and impact on work/school and relationships; developmental history; personal and family psychiatric history, including substance abuse; social history, including family dysfunction; medical history.
- Physical examination should be performed to investigate medical causes for symptoms, coexisting conditions, and contraindications to treatment. Special focus should be paid to evaluation of dysmorphic features; neurologic examination, including assessment for neurocutaneous findings; and assessment of hearing and vision.
- Information from collateral sources (parents, partners, teachers) is crucial to diagnosis. Many patients will not display symptoms during an office visit and may underreport or overreport symptoms.
- Self-rating scales and standardized symptom-specific questionnaires from collateral sources can help diagnose and assess response to treatment. The use of ADHD-specific rating scales over broadband behavioral scale is associated with improved sensitivity and specificity.
- Laboratory or imaging studies should be undertaken only if indicated by history or physical examination.
- The FDA has approved a quantitative electroencephalogram test to aid in the diagnosis of ADHD in children, but sufficient evidence to support its routine use is lacking.
- Ancillary testing (e.g., neuropsychological testing including verbal and performance IQ/achievement testing and language evaluation, and mental health assessment) may be indicated based on clinical findings and may require referral.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- The majority of studies comparing the efficacy of pharmacologic vs. nonpharmacologic interventions demonstrate the superiority of pharmacologic treatments.
- Studies on combined treatments have not shown significant improvements in core ADHD symptoms when behavioral treatments are added to stimulant medications. However, improvements in related areas of concern such as parent-child relations, aggressiveness, teacher-rated social skills, and reaching achievement have been seen in combined treatment groups.
- Prevailing opinion favors a multimodal approach in which nonpharmacologic behavioral therapies including parent-child behavioral therapy and social skills training can be used to target comorbid conditions or behaviors that have not responded to medication.
- Behavioral therapy alone is often considered when children are under 6 yr, symptoms and impairment are mild, if parents are opposed to or patients cannot tolerate medications, or if there is uncertainty or disagreement about the diagnosis (e.g., between parents and teachers).
- Educational interventions are recommended, particularly in the setting of learning disabilities. Children with ADHD are entitled to reasonable educational accommodations under a 504 Plan or the Individuals with Disabilities Education Act.
- Behavioral interventions (e.g., goal setting and rewards systems) show short-term efficacy and are endorsed by most national organizations. Time management and organizational skills appear useful. Social skills training may also be useful.
- Psychotherapy such as cognitive therapy, play therapy, or insight-oriented therapy are unlikely to be useful in addressing the core symptoms of ADHD. However, it may be beneficial in treating comorbid psychiatric conditions.
- Preliminary research concentrating on improving diagnosis, treatment outcomes, and medication compliance using eHealth (telemedicine, mobile apps, text reminders) have been promising.
- Elimination diets are not routinely recommended.
- Many support and advocacy groups provide education and other resources (e.g., Children and Adolescents with ADHD, National ADD Association, American Academy of Child and Adolescent Psychiatry).

ACUTE GENERAL Rx

- Most studies on treatment of ADHD are performed in children; limited data available on adults.
- Mainstay of treatment is stimulant medication. Second-line therapies include antidepressants and alpha-agonists. Table 2 summarizes FDA-approved treatments for ADHD.
- Stimulants:
  1. Release or block uptake of dopamine and norepinephrine.
  2. Include short- and long-acting methylphenidate, dextroamphetamine, and dextroamphetamine/amphetamine combinations (mixed amphetamine salts). A methylphenidate patch (Daytrana) is available, as is a pro-drug form of dextroamphetamine, lisdexamfetamine (Vyvanse), which is designed to limit the abuse potential. A long-acting oral suspension of methylphenidate (Quillivant XR), a long-acting chewable tablet of methylphenidate

TABLE 2 FDA-Approved Treatments for Attention Deficit Hyperactivity Disorder

Generic Name	Brand Name	Formulations and Strengths	Duration of Behavioral Effect (h)	Comments
Amphetamines				
D-amphetamine	Dexedrine	Tablets: 5, 10 mg	3-6	
	Dexedrine Spansule	Spansules: 5, 10, 15 mg		
	ProCentra	Oral solution: 5 mg/5 ml		
Mixed amphetamine /dextroamphetamine	Adderall	Tablets: 5, 7.5, 10, 12.5, 15, 20, 30 mg	4-6	
	Adderall XR	Capsules: 5, 10, 15, 20, 25, 30 mg	8-10	Capsule with 1:1 ratio of IR to DR beads
	Evekeo	Tablets: 5, 10 mg	10	Racemic amphetamine sulfate, 1:1 D-amphetamine and L-amphetamine
	Dyanavel	Oral suspension: 2.5 mg/ml	8-13	Shake the bottle before administering the dose
Lisdexamfetamine dimesylate	Vyvanse	Capsules: 20, 30, 40, 50, 60, 70 mg	8–12	Inactive prodrug in which L-lysine is chemically bonded to D-amphetamine
Methylphenidates				
Methylphenidate	Ritalin	Tablets: 5, 10, 20 mg	3-4	
	Methylin	Tablets, chewable: 2.5, 5, 10 mg	3-4	
		Oral solution: 5 mg/5 ml, 10 mg/5 ml (500 ml)	3-4	
	Ritalin LA	Capsules: 10, 20, 30, 40 mg	8-9	Capsule with 1:1 ratio of IR beads to DR beads
	Metadate ER	Tablets: 10, 20 mg	5-8	
	Metadate CD	Capsules: 10, 20, 30 mg	8-9	Capsule with 3:7 ratio of IR beads to DR beads
	Concerta	Tablets: 18, 27, 36, 54 mg	8-12	Ascending profile, OROS technology
	Daytrana	Transdermal patch: 10, 15, 20, 30 mg/9 h	9	Delivery rate of 1.1, 1.6, 2.2, 3.3 mg/h for the patches, respectively, based on 9-h wear times in patients ages 6-12 yr
	Quillivant XR	Oral suspension: 25 mg/ 5 ml	8-12	Shake the bottle before administering the dose
	QuilliChew ER	Chewable tablets: 20, 30, 40 mg	8	
	Aptensio XR	Capsules: 10, 15, 20, 30, 40, 50, 60 mg	9-12	May be swallowed or opened and contents mixed into food.
Dexmethylphenidate	Focalin	Tablets: 2.5, 5, 10 mg		*d-threo*-enantiomer of methylphenidate, twice as potent as racemic methylphenidate
	Focalin XR	Capsules: 5, 10, 20 mg		

DR, Delayed-release; *IR,* immediate-release; *OROS,* osmotic-controlled release oral delivery system.
From Stern TA et al: *Massachusetts General Hospital handbook of general hospital psychiatry,* ed 7, Philadelphia, 2018, Elsevier.

(QuilliChew ER), a long-acting orally disintegrating tablet of mixed amphetamine preparation (Adzenys XR-ODT), and a long-acting liquid amphetamine preparation (Dyanavel XR) are also available.

3. All stimulants equally effective; however, not all patients improve with stimulants. Patients who do not respond well to one stimulant may respond to another.
4. Do not cause euphoria or lead to addiction when taken as directed.
5. Improve cognition, inattention, impulsiveness/hyperactivity, and driving skills. Limited impact on academic performance, learning, and emotional problems.
6. Side effects are usually mild, reversible, and dose dependent, including anorexia, weight loss, sleep disturbances, increased heart rate and blood pressure, irritability, moodiness, headache, onset or worsening of motor tics, reduction of growth velocity (but not adult height). Do not worsen seizures in patients on adequate anticonvulsant therapy. Rebound of symptoms can occur with withdrawal of medication.
7. Stimulants are associated with an increased risk of cardiovascular events and death. Patients should be carefully evaluated for cardiovascular disease before beginning therapy and be periodically monitored, including blood pressure checks, while they are treated. However, despite concerns regarding cardiovascular risk, these medications are generally safe. Recent studies have shown that among young and middle-aged adults, current or new use of ADHD medications, compared with nonuse or remote use, is not associated with an increased risk of serious cardiovascular events. Routine, pre-treatment screening with ECGs is not currently recommended by the American Academy of Pediatrics or the American Academy of Child and Adolescent Psychiatry.
8. There are reports of psychotic or manic symptoms (particularly hallucinations) associated with stimulant use in children and adolescents, with a 2006 report revealing that these symptoms might emerge in 0.25% of treated children (1 in 400) (Ross RG: *Am J Psychiatry* 163:1149-1152, 2006).

- Atomoxetine (Strattera):
  1. Selective norepinephrine reuptake inhibitor.
  2. Generally felt to be less effective than stimulants, but a useful alternative in patients who have not tolerated or responded to stimulants or in the setting of patient or family substance abuse.
  3. Efficacy and safety of use beyond 2 yr of treatment have not been studied. There have been reports of behavioral abnormalities and increased suicidality in children and adolescents.
  4. Side effects: Gastrointestinal upset, sleep disturbance, decreased appetite, dizziness, sexual side effects in men. Cardiovascular side effects have also been reported.
  5. There have been rare reports of severe liver injury in adults and children.
- Antidepressants (bupropion, imipramine, desipramine, nortriptyline):
  1. May be useful in patients with coexisting psychiatric disorders.
  2. Studies comparing efficacy versus stimulants are inconclusive.
  3. Side effects: Arrhythmias, anticholinergic effects, lowering of seizure threshold.
- Alpha-2-adrenergic agonists (clonidine, guanfacine):
  1. Appear to be less effective than stimulants, but may be particularly useful as an adjunctive treatment to stimulants, particularly in patients with a partial stimulant response or who experience side effects such as sleep disturbance or concurrent symptoms of overarousal, irritability, or aggression.
  2. Extended-release formulations of guanfacine (Intuniv) and clonidine (Kapvay) have been approved by the FDA for treatment of ADHD in children ages 6 to 17 yr. A transdermal clonidine patch is also available.
  3. Potential side effects include sedation, fatigue, headache, bradycardia, hypotension, and depression.
- Use of medications, particularly stimulants (which are monitored under the Controlled Substance Act), requires frequent monitoring.

DISPOSITION

- Although symptoms may change over time, for many patients ADHD represents a chronic condition that requires lifelong management.
- Patients are at higher risk for academic underachievement, lower socioeconomic status, work and relationship difficulties, high-risk behavior, and psychiatric comorbidities.

REFERRAL

- Diagnosis complicated by difficult-to-treat comorbid psychiatric conditions, developmental disorders, or mental retardation
- Lack of adequate response to stimulants/atomoxetine/alpha-adrenergic agents

PEARLS & CONSIDERATIONS

- The World Health Organization's Adult Self-Report Scale (ASRS) v1.1 has good sensitivity and adaptability to the primary care setting.
- Among adults with persistent ADHD symptoms treated with medication, trials have shown that the use of cognitive behavioral therapy compared with relaxation with educational support resulted in improved ADHD symptoms, which were maintained at 12 mo.
- ADHD has been associated with criminal behavior in some studies. Data analysis has shown that among patients with ADHD, rates of criminality are lower during periods when they receive ADHD medication.
- Recommendations for the diagnosis and management of ADHD have been published by the Centers for Disease Control and Prevention (www.cdc.gov/ncbddd/adhd/guidelines.html).

BASIC INFORMATION

DEFINITION

Autism spectrum disorder (ASD) encompasses a continuum of developmental disabilities characterized by marked social impairment. Box 1 describes the diagnostic keys and case determination criteria under *Diagnostic and Statistical Manual of Mental Disorders* (DSM-5). There is usually impairment in several additional domains integral to social functioning, including communication, language, and social interactions. Repetitive/stereotyped behaviors and interests as well as sensory issues (i.e., hypersensitivity, hyposensitivity) also are prominent. Comorbid intellectual disability, neurological and medical problems, and an increased risk of psychiatric disorders are frequently present in ASD. Both core and associated features can vary dramatically among individuals. In addition, timing of onset can differ, as about one quarter of children with ASD are noted to lose skills after developing normally for as long as 2 yr, whereas others present with delays across most developmental domains within the first year of life. The diagnosis of ASD can accurately be made by 3 yr of age. However, gender and cognitive, linguistic, and adaptive functioning impact ASD presentation and can affect age of diagnosis. DSM-5 criteria no longer differentiate separate disorders. Instead, an overarching diagnosis of ASD is given; severity levels (1, 2, or 3) have been introduced to identify the magnitude of social and behavioral impairment and the support required to ensure the safety and well-being of the individual. Specifiers have been added to capture associated features (e.g., intellectual disability, language impairment, medical or genetic conditions, and catatonia).

SYNONYMS

ASD
Autism
Autistic disorder
Early infantile autism
Childhood autism
Kanner autism
Asperger disorder
Pervasive developmental disorder
Pervasive developmental disorder–not otherwise specified (PDD-NOS)

ICD-10CM CODES
F84.0 Autism spectrum disorder
DSM-5 CODES
299.00 Autism spectrum disorder

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Autism spectrum disorder afflicts up to 3% of children in the United States.
PREVALENCE: 1:68 (1:42 for boys, 1:189 for girls). It is unclear whether the increase in prevalence reflects an expansion of the diagnosis to include subthreshold cases, increased awareness of the disorder, improvement in diagnostic accuracy, changes in public policy related to service eligibility, or a true increase in the frequency of autism spectrum disorder.
PREDOMINANT SEX AND AGE: Male:female ratio of 2 to 5:1. Lifelong.
PEAK INCIDENCE: Before age 3 yr
RISK FACTORS: Prenatal and perinatal risk factors identified include hypoxia-related obstetric complications, use of valproic acid during pregnancy, use of thalidomide during pregnancy, advanced parental age, multiple birth, prematurity, congenital sensory deficits, and significant exposure to air pollutions (during pregnancy and in the postnatal period). However, it is not established whether these are causal factors.
GENETICS:

- Autism spectrum disorder is highly inheritable with a heritability index of 82% to 90%.
- The concordance rate for ASD varies across studies and ranges from 36% to 95% for monozygotic twins; the concordance rate is estimated between 20% and 40% for dizygotic twins and between 10% and 20% for non-twin siblings.
- Copy number variants (CNVs) account for 10% to 20% of autism spectrum disorder cases, but each CNV is rare (no more than 1% of cases). Rare chromosomal abnormalities account for about 10% of cases, but each type is rare (no more than 1% of cases).
- Common genetic variants acting in an additive manner account for approximately 35% of cases. Research has identified approximately 1000 gene mutations as being possibly contributory, but only about 20 of them have been associated with ASD with "high confidence."
- In the remaining cases, ASD is suggested to arise from a combination of unknown genetic variations, environmental influences, and epigenetic factors.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Common triad of marked impairment in social interactions (poor social-emotional reciprocity), impaired and atypical verbal and nonverbal communication, and repetitive and unusual behavior or play
- Marked impairment in the understanding and use of both verbal and nonverbal communication, including unchanging facial expression and lack of gestures during interactions
- Stereotypic behavior (i.e., hand flapping, body rocking) or language (i.e., echolalia, palilalia)
- Perceptual hypersensitivity (i.e., auditory, tactile, olfactory, gustatory) and avoidance of novel stimuli; or perceptual hyposensitivity (e.g., abnormally high threshold for pain)
- Brain abnormalities have been identified at anatomical and functional levels; abnormalities are detected as early as the first year of

BOX 1 Autism Spectrum Disorder (ASD) Case Determination Criteria under DSM-5

DSM-5 Behavioral Criteria	
A. Persistent deficits in social communication and social interaction	A1: Deficits in social emotional reciprocity A2. Deficits in nonverbal communicative behaviors A3. Deficits in developing, maintaining, and understanding relationships
B. Restricted, repetitive patterns of behavior, interests, or activities, currently or by history	B1: Stereotyped or repetitive motor movements, use of objects or speech B2. Insistence on sameness, inflexible adherence to routines, or ritualized patterns of verbal or nonverbal behavior B3. Highly restricted interests that are abnormal in intensity or focus B4. Hyper- or hyporeactivity to sensory input or unusual interest in sensory aspects of the environment
Historical PDD diagnosis	Any ASD diagnosis documented in a comprehensive evaluation, including a DSM-IV diagnosis of autistic disorder, Asperger disorder, or pervasive developmental disorder–not otherwise specified (PDD-NOS)
DSM-5 case determination	All three behavioral criteria coded under part A, and at least two behavioral criteria coded under part B OR Any ASD diagnosis documented in a comprehensive evaluation, whether based on DSM-IV-TR or DSM-5 diagnostic criteria NOTE: A child might be disqualified from meeting the DSM-5 surveillance case definition for ASD if, based on the clinical judgment of one or more reviewers, there is insufficient or conflicting information in support of ASD, sufficient information to rule out ASD, or if one or more other diagnosed conditions better account for the child's symptoms.

DSM-IV, *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition*; DSM-IV-TR, *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision*; DSM-5, *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*; *PDD*, pervasive developmental disorder.

Baio J et al: Prevalence of autism spectrum disorder among children aged 8 years—Autism and Developmental Disabilities Monitoring Network, 11 Sites, United States, 2014. *MMWR Surveill Summ* 67(No. SS-6):1-23, 2018. https://dx.doi.org/10.15585/mmwr.ss6706a1.

BOX 2 Red Flags for Social Communication Development

Prompt evaluation should occur for any of the following: **No vocalizations by 6 months:** *A parent should be able to have a reciprocal "conversation" by this age, consisting of at least several volleys back and forth.* **No polysyllabic consonant babbling by 12 months:** *At least some of these vocalizations should be directed at someone with communicative intent.* **No gestures by 12 months:** *The earliest gesture an infant learns is to raise his/her arms to request to be picked up, usually once sitting independently. Pointing should be with an isolated index finger, not the whole hand, and should be used "to request" or "to show," not just pointing at pictures in a book or pointing to have an adult label items. Any use of hand-over-hand by the child (e.g., putting a parent's hand on the cabinet door where the cookies are kept or using the parent's hand to point at pictures in a book) is a hallmark of ASD.* **No spontaneous (not echoed) single words by 16 months other than mama or dada:** *Spontaneous words must be beyond those used to simply label items and must be used by the child to communicate, to request, to show, or to share.* **No spontaneous (not echoed) phrases by 24 months or sentences by 36 months:** *Spontaneous phrases and sentences must be used by the child to communicate, to request, to show, or to share.* **Any loss of social communication abilities, including babbling, single words, phrases, response to name, social engagement, or gestures:** *If a parent reports their infant has decreased or stopped any social communication milestones, this is usually the hallmark of the onset of regression.*

Swaiman KF et al: *Swaiman's pediatric neurology, principles and practice*, ed 6, Philadelphia, 2017, Elsevier.

life and are accompanied by atypical brain maturation trajectories
- No biomarkers have been identified

ETIOLOGY

- Majority of cases are not associated with a comorbid medical condition
- High prevalence of comorbid seizure disorder (25%) and/or intellectual disability (up to 75%)
- Sometimes present in the context of medical conditions (e.g., encephalitis, cytomegalovirus, toxoplasmosis, phenylketonuria [PKU], fragile X syndrome, tuberous sclerosis complex, neurofibromatosis)
- Numerous studies have shown **no** association between immunizations (specifically MMR vaccine) or thimerosal-containing vaccines (i.e., diphtheria, pertussis, and tetanus) and autism spectrum disorder

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Several genetic syndromes manifest with a phenotype similar to ASD (e.g., 22q11.2 deletion syndrome, Angelman syndrome, Aicardi syndrome, Cornelia de Lange syndrome, Christianson syndrome, fragile X syndrome, Landau-Kleffner syndrome, Klinefelter syndrome, neurofibromatosis, Prader-Willi syndrome, Rett syndrome, tuberous sclerosis complex, Williams syndrome).
- Several psychiatric or neurodevelopmental disorders present with symptoms similar to ASD (e.g., Tourette syndrome, selective mutism, catatonia, social phobia, obsessive/compulsive disorder, expressive language disorder, mixed receptive-expressive language disorder, stereotypic movement disorder, intellectual disability). Differences are notable in onset of symptoms and developmental trajectories.
- Social (pragmatic) communication disorder, introduced in DSM-5 and characterized by significant difficulties with verbal and nonverbal communication.
- Childhood-onset schizophrenia: Follows period of normal development.
- Attachment disorders (reactive attachment disorder, disinhibited social engagement disorder); individuals with these disorders can present with language delays, cognitive delays, social difficulties, and stereotypies. Differences are notable before 5 yr of age.

WORKUP

- Rule out underlying medical condition, including genetic syndromes.
- "Red flags" for critical delays in social communication development should be recognized or queried and should initiate evaluation for an ASD (Box 2). Validated autism spectrum disorder–specific screening tools are available for children age ≥18 mo. All children should be screened specifically for ASD at 18 and 24 mo. General developmental screening tools are currently used in children 9 to 18 mo.
- Gold standard assessment includes detailed developmental and family history, assessment of developmental/intellectual functioning, assessment of ASD symptomatology, and assessment of adaptive behaviors.
- Additional workup may include assessment of language functioning, neuropsychological functioning, and psychiatric presentation.

LABORATORY TESTS

- PKU screen (usually done at birth in the United States)
- Lead exposure screening
- Audiology testing for young children with ASD; school-based hearing screening may be sufficient in older children with autism spectrum disorders and without significant language or learning deficits
- Karyotype, chromosome microarray analysis, and DNA testing for fragile X syndrome in both boys and girls, as well as for different de novo copy number variants or mutations in specific genes associated with the disorder

IMAGING STUDIES

- Electroencephalogram to diagnose coexisting seizure disorder if seizures are suspected or if language regression is present (i.e., Landau-Kleffner syndrome)
- Brain MRI if tuberous sclerosis complex or Aicardi syndrome (callosal agenesis) is suspected

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Consistent behavioral training program in both the home and school environments
- A number of treatment programs have been developed; many are based on applied behavioral analysis (ABA) (e.g., Discrete Trial Training); others combine ABA procedures with social-emotional development (e.g., Pivotal Response Training, Floortime, Early Start Denver Model)
- Special educational program focused on language and communication skills, social and life skills development (e.g., TEACCH)
- Cognitive-Behavioral Therapy (CBT) has proven effective to ameliorate symptoms of anxiety in higher functioning individuals with ASD
- Highly structured home environment
- Education for families and teachers; the Autism Speaks™ website may be helpful in this regard: www.autismspeaks.org

ACUTE GENERAL Rx

- Obsessive or ritualistic behaviors: Selective serotonin reuptake inhibitors (SSRIs), atypical antipsychotics, valproic acid
- Aggression, irritability, self-injury: Atypical antipsychotic agents (e.g., risperidone), anticonvulsant mood stabilizers, SSRIs, beta-blockers, opiate antagonist (self-injury only)
- Hyperactivity, impulsivity, inattention: Stimulants, α-2 adrenergic agonists, atypical antipsychotics
- Anxiety: SSRIs, buspirone, mirtazapine
- Mood lability: Valproic acid, carbamazepine, lithium, aripiprazole
- Depression: SSRIs, mirtazapine
- Catatonia: Avoid antipsychotics, which make catatonia worse and potentially malignant, and use lorazepam; if unsuccessful, electroconvulsive therapy may be indicated
- Only risperidone and aripiprazole are FDA-approved for the management of symptoms associated with ASD
- Medications used to decrease specific symptoms associated with Autism Spectrum Disorder are summarized in Table 1

CHRONIC Rx

- Extended use of medications for acute management of comorbid psychiatric disorder
- Use of medications for comorbid medical conditions, including sleep problems and gastrointestinal problems
- Pharmacotherapy is palliative, not curative, of autism spectrum disorder

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Preliminary evidence is available for effectiveness of melatonin in ameliorating sleep problems.

TABLE 1 Medications Used to Decrease Specific Symptoms Associated with Autism Spectrum Disorder *

Drug	Dose	Age†	N	Efficacy	Side Effects
Neuroleptic Agents					
Risperidone	0.25-2.5 mg/d <20 kg 0.5-2.5 mg/d 20-45 kg 0.5-3.5 mg/d >45 kg Mean = 2.4 mg/d	5-17	101	Decreased tantrums, aggression, self-injury, hyperactivity	Weight gain, increased appetite, transient sedation
Risperidone	1.2-2.9 mg/d child Mean = 2.0 mg/d 2.4-5.3 mg/d adult Mean = 3.6 mg/d	8-56	36	Decreased irritability, hyperactivity	Increased appetite, weight gain, sedation
Risperidone	0.125-0.175 vs. 1.25-1.75 vs. placebo	5-17	96	Higher dose improves global function and irritability	Somnolence sedation increased appetite
Risperidone	0.01-0.06 mg/kg/d Mean = 1.17 mg/d	5-12	79	Decreased irritability, hyperactivity, noncompliance, conduct problems	Weight gain, transient somnolence, mildly increased heart rate and blood pressure
Risperidone	0.5-1.5 mg/d Mean = 1.14 mg/d	2.5-6	24	Minimal improvement in global autism severity scores	Weight gain, increased prolactin levels
Risperidone	1.0-10.0 mg/d	18-43	n =?	Reduced repetitive behavior, aggression, self-injury, property destruction	Transient sedation
Aripiprazole	5 mg/d, 10 mg/d, or 15 mg/d	6-17	218	Reduced irritability, hyperactivity, stereotypy at all doses	Sedation, EPS, weight gain
Aripiprazole	2-15 mg/d	6-17	98	Reduced irritability, hyperactivity, stereotypy, inappropriate speech, global improvement	Decreased prolactin level, weight gain, EPS
Aripiprazole	2-15 mg/d continuation active tx vs. placebo	6-17	85	No difference in time to relapse	
Opiate Antagonists					
Naltrexone	1.0 mg/kg/d	3-8	41	No improvement over placebo in behavior and learning; improved hyperactivity	None greater than placebo
Naltrexone	1.0 mg/kg/d 2 weeks only	3-8	24	No improvement in communication skills	Transient sedation
Naltrexone	40 mg/d Single dose	3-7	23	Decreased hyperactivity, improved attention	Not reported
Naltrexone	1 mg/kg/dose	3-7	23	Decreased hyperactivity and improved attention by teacher, but not parent, report	No side effects
Serotonin Reuptake Inhibitors					
Fluvoxamine	Mean dose = 276.7 mg/d	18-53	n = 30	Reduced repetitive thoughts and behavior, and aggression; improved social communication	Transient nausea and sedation
Buspirone	2.5 mg or 5 mg/d	2-6	166	Improvement in repetitive behaviors not total ADOS	
Clomipramine	5-10 mg/d	8-17	34	No improvement executive function	Diarrhea, headache, fatigue
Fluoxetine	4.8-20 mg/d Mean = 10.6 mg/d; 0.38 mg/kg/d	5-17	39	Modest reduction in repetitive behaviors, but no improvement in global functioning	Agitation requiring dose reduction
Citalopram	2.5-20 mg/d Mean = 16.5 mg/d	5-17	149	No improvement in repetitive behavior or global functioning	Increased energy, inattention, impulsivity, hyperactivity, stereotypy, diarrhea, insomnia, dry skin
Stimulants					
Methylphenidate	0.125, 0.25, or 0.5 t.i.d. mg/kg/day	5-14	72	Reduced inattention, distractibility, hyperactivity, and impulsivity	Irritability, decreased appetite, difficulty falling asleep, emotional outbursts
Methylphenidate	0.25, 0.5 mg/kg/dose	5-13	33	Positive efforts on social behavior	None discussed
Methylphenidate	10-40 LA AM, 2.5-10 mg afternoon	7-13	24	Decreased hyperactive and impulsive behavior	Loss of appetite, insomnia
Atomoxetine	20-100 mg/d Mean = 44.2 mg/d	5-15	16	Reduced hyperactivity, impulsivity, social withdrawal	Transient nausea and fatigue
Antiseizure Drugs					
Lamotrigine	Mean = 5.0 mg/kg/d	3-11	28	No improvement greater than placebo in disruptive behavior and autism symptoms	Aggression, insomnia, echolalia
Levetiracetam	20-30 mg/kg/d	5-17	20	No improvement in disruptive behavior or irritability	Aggression, agitation
Divalproex sodium	500-1500 mg/d	5-17	13	Reduction in compulsive-type repetitive behavior	Irritability, weight gain, aggression
Divalproex sodium	125 mg QD titrated up to 500 bid	5-17	27	Reduction in irritability	Irritability
Bumetanide	0.5 mg bid	3-11	60	Improved autistic behaviors and global function	Diarrhea, increased irritability

ADOS, Autism Diagnostic Observation Schedule; *EPS,* extrapyramidal symptoms; *LA AM,* L-alpha-acetylmethadol; *QD,* every day; *t.i.d.,* three times per day; *tx,* treatment.
*Includes only double-blind, randomized, placebo-controlled trials.
†Age in years.
Swaiman KF et al: *Swaiman's pediatric neurology, principles and practice*, ed 6, Philadelphia, 2017, Elsevier.

- Very limited rigorous evidence is available on the effectiveness of complimentary and alternative medicine, including nutritional interventions.

DISPOSITION

- Most children will require some degree of assistance as adults.
- DSM-5 identifies three severity levels based on social communication and restricted, repetitive behaviors: Level 1 (requiring support), Level 2 (requiring substantial support), and Level 3 (requiring very substantial support).
- With early diagnosis and proper treatment/support, the prognosis for children without language and intellectual impairment is fair to very good despite lifelong symptoms.
- Poorer outcomes include a lack of joint attention by age 4 yr, a lack of functional speech by age 5 yr, intellectual disability, seizures, comorbid medical or psychiatric syndromes, and a pervasive lack of social relatedness.
- Best outcomes are associated with early identification and treatment, the development of oral communication skills, and the cognitive and behavioral capacity for inclusion in regular education settings with typically developing peers.

REFERRAL

Assistance may be needed in diagnosis (child psychiatrist, clinical psychologist, geneticist, pediatric neurologist, developmental pediatrician), symptom management (speech language pathologist, occupational therapist, clinical psychologist), parental teaching (clinical psychologist, psychiatric social worker), and intervention with the school system (educational advocate, attorney).

PEARLS & CONSIDERATIONS

- There is no scientific evidence of a relation between childhood vaccination and the development of autism spectrum disorder.
- Evidence suggests that a disproportionate number of children with autism spectrum disorder suffer from a variety of medical problems including sleep difficulties, gastrointestinal problems, and oral health problems.
- Psychiatric comorbidities are very prominent across the life span, with estimated prevalence ranging from 30% to 70%.
- The new U.S. Preventive Services Task Force (USPSTF) recommendation on screening for ASD in young children concludes that the current evidence is insufficient to assess the balance of benefits and harms of screening for ASD in young children for whom no concerns of ASD have been raised by their parents or a clinician.
- A recent trial has shown that daily intranasal oxytocin improves social behavior in kids with ASD whose baseline endogenous blood oxytocin levels are low.[1]

BASIC INFORMATION

DEFINITION

Autoimmune hepatitis (AIH) is a chronic inflammatory condition of the liver characterized by elevated serum globulin levels (IgG), presence of circulating autoantibodies, interface hepatitis on histology, and plasma cell rich infiltrate. Three types have been described:

- Type 1, or "classic," autoimmune hepatitis is the most predominant form in the U.S. and worldwide (80%) and has a bimodal age distribution with peaks between 10 and 20 and 45 and 70 yr of age. Patients are positive for antinuclear antibodies (ANA) and/or anti-smooth muscle antibodies (ASMA) and have specific associated human leukocyte antigen (HLA) haplotypes: DR3, DR4, DR13. Usually excellent treatment response, but variable relapse rates after drug withdrawal; usually need for long-term maintenance therapy.
- Type 2, up to 10% of AIH cases, primarily affects young children between 2 and 14 yr of age, and is characterized by the presence of antibodies to liver/kidney microsomes (anti-LKM-1) or liver cytosol 1. Patients have associated HLA haplotypes: DR3 and DR7. This form is generally more advanced at presentation and is more difficult to treat; need for long-term maintenance therapy is very common.
- Type 3, up to 10% of AIH cases, only soluble liver antigen/liver pancreas antigen (SLA/LP) positive, otherwise very similar to AIH-1. Often Ro52-antibody positive. Lifelong immunosuppression in most, if not all patients.

SYNONYMS

Autoimmune chronic active hepatitis
AIH
Chronic active hepatitis
Lupoid hepatitis
Plasma cell hepatitis

ICD-10CM CODES

K75.4 Autoimmune hepatitis
K73.2 Chronic active hepatitis, not elsewhere classified

EPIDEMIOLOGY & DEMOGRAPHICS

- Annual incidence (estimated): 0.2 to 2.0 cases per 100,000, similar to primary biliary cirrhosis (PBC), more common than primary sclerosing cholangitis (PSC).
- Point prevalence (estimated): 16.9 per 100,000.
- Type 1: Age of onset has a bimodal distribution with peaks between 10 and 20 and 45 and 70 yr.
- Type 2: More common in young children 2 to 14 yr of age.
- Female:male ratio is 3.6:1; type 1 has an 80% female predominance, whereas type 2 has a 90% female predominance.
- Approximately 100,000 to 200,000 persons affected in the U.S.
- Accounts for 4% to 6% of liver transplants in the U.S.
- Associated with HLA-DRB1*0301 and HLA-DRB1*0401 alleles.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Varies from intermittent asymptomatic elevations of liver enzymes to advanced cirrhosis. One third of adults and one half of child patients with AIH have cirrhosis at presentation. AIH can also present initially as a fulminant hepatitis.
- Symptoms may include fatigue, anorexia, nausea, abdominal pain, pruritus, and arthralgia.
- Autoimmune findings may include arthritis, xerostomia, keratoconjunctivitis, cutaneous vasculitis, and erythema nodosum.
- Patients with advanced disease can show hepatosplenomegaly, ascites, peripheral edema, abnormal bleeding, and jaundice.

ETIOLOGY

- Exact etiology is unknown; liver histology demonstrates cell-mediated immune attack against hepatocytes.
- Presence of a variety of autoantibodies suggests an autoimmune mechanism.
- Observational studies have supported the idea of the main inflammatory activity being driven by T cells recognizing antigens expressed in the liver.
- There are likely two components involved: genetic predisposition and an inciting environmental trigger.
- Potential triggering agents such as viruses (hepatitis A, B, C) or drugs (minocycline, nitrofurantoin, biological agents, tumor necrosis factor [TNF] blockade) likely possess some homology similar to liver-specific antigens.

DIAGNOSIS

- A simplified diagnostic criteria for routine clinical practice has been developed by the International Autoimmune Hepatitis Group (see Table 1).
- Suggestive findings on histology: Lymphoplasmacytic infiltrate invading the hepatocyte boundary surrounding the portal triad (limiting plate). Also, a periportal infiltrate may be seen (interface hepatitis). Pericentric necrosis may be present in acute-onset AIH, indistinguishable from drug-induced liver injury (DILI).
- If coexistent findings of cholestatic liver disease on histology, rule out PSC and PBC, consider magnetic resonance cholangiography.
- The European Association for the Study of the Liver guidelines require liver biopsy as part of the diagnostic evaluation.
- The American Association for the Study of Liver Disease (AASLD) approach is to obtain a liver biopsy if the diagnosis is unclear or to assess disease activity prior to initiating treatment.

DIFFERENTIAL DIAGNOSIS

AIH should be considered in any patient with acute or chronic liver disease.

- Acute viral hepatitis (A, B, C, D, E, cytomegalovirus, Epstein-Barr, herpes)
- Chronic viral hepatitis (B, C)
- Toxic hepatitis (alcohol, drugs)
- Primary biliary cirrhosis
- Primary sclerosing cholangitis
- Hemochromatosis
- Nonalcoholic steatohepatitis
- Systemic lupus erythematosus
- Wilson disease
- Alpha-1 antitrypsin deficiency

WORKUP

- History and physical examination with attention to the presence of autoimmune abnormalities such as autoimmune thyroiditis, Graves disease, inflammatory bowel disease, celiac sprue, and rheumatoid arthritis. Fig. 1 illustrates a diagnostic algorithm for autoimmune hepatitis
- Liver function tests and serum gamma-globulins
- Tests for autoantibodies: ANA, ASMA, anti-LKM, SLA/LP
- Liver biopsy for establishing diagnosis and disease severity

LABORATORY TESTS

- Aminotransferases generally elevated and may fluctuate, generally alanine aminotransferase (ALT) > aspartate aminotransferase (AST)
- Bilirubin and alkaline phosphatase moderately elevated or normal
- Elevation of gamma globulin (>2.0 g/dl [20 g/L]) and immunoglobulin G seen in 90% of patients, seen as markers of activity
- Circulating autoantibodies (Table E2) often present:
  1. Rheumatoid factor
  2. ANA:
     a. Present in two thirds of patients
     b. Typical pattern is homogeneous or speckled
     c. Titer does not correlate with the stage, activity, or prognosis

TABLE 1 Simplified Diagnostic Criteria for Autoimmune Hepatitis

Variable	Cutoff	Points	Cutoff	Points
ANA or SMA	≥1:40	1	≥1:80	2
LKM			≥1:40	2
SLA			Positive	2
IgG	≥ULN	1	≥1.1 × ULN	2
Histology	Compatible with AIH	1	Typical of AIH	2
Absence of viral hepatitis			Yes	2

Maximum number of points for all antibodies = 2, total = 8. Probable AIH ≥6 points, definite AIH ≥7 points. 88% sensitivity and 97% specificity. *AIH,* Autoimmune hepatitis; *ANA,* antinuclear antibody; *IgG,* immunoglobulin G; *LKM,* liver/kidney microsomes; *SLA,* soluble liver antigen; *SMA,* smooth muscle antibody; *ULN,* upper limit of normal.

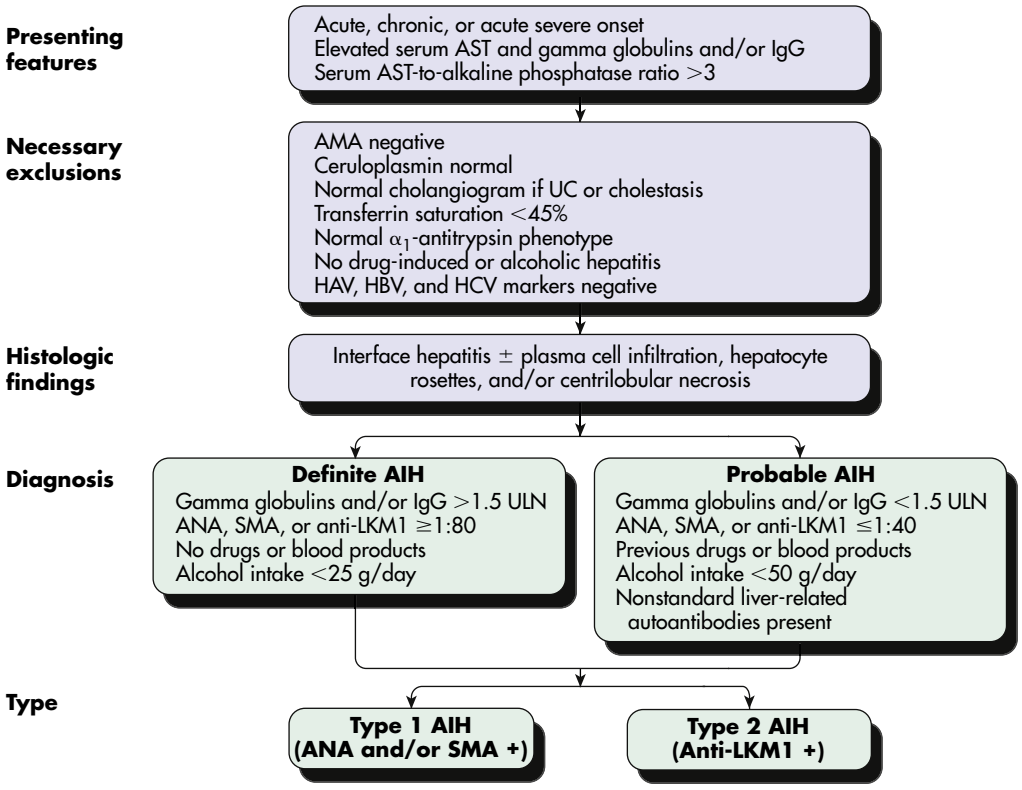

FIG. 1 Diagnostic algorithm for autoimmune hepatitis *(AIH)*. The diagnosis requires predominant elevation of the serum AST level and exclusion of other hepatic diseases (especially primary biliary cirrhosis, primary sclerosing cholangitis, Wilson disease, hemochromatosis, α1-antitrypsin deficiency, drug-induced or alcoholic hepatitis, and viral hepatitis). Antimitochondrial antibodies *(AMA)* should be absent; cholangiography should be negative in patients with concurrent UC or cholestasis; and the serologic markers of HAV, HBV, and HCV should be negative. Interface hepatitis should be present on histologic examination, and laboratory manifestations of immune reactivity should be evident by abnormal elevation of the serum gamma globulin and/or immunoglobulin G *(IgG)* level and the presence of antinuclear antibodies *(ANA)*, smooth muscle antibodies *(SMA)*, or antibodies to liver kidney microsome type 1 *(anti-LKM1)*. The degree of immune reactivity and the presence of confounding etiologic factors, such as alcohol and drug or blood product exposure, distinguish definite from probable AIH. Classification as type 1 AIH or type 2 AIH is based on the type of autoantibodies that predominate in the disease. *AST*, Aspartate aminotransferase; *HAV*, hepatitis A virus; *HBV*, hepatitis B virus; *HCV*, hepatitis C virus; *UC,* ulcerative cholitis; *ULN*, upper limit of normal. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fortran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.)

3. Anti-SMA:
   a. Present in 87% of patients
   b. Titer does not correlate with course or prognosis
4. Anti-LKM antibodies:
   a. Typically found in patients who are ANA negative and SMA negative
   b. Characterizes type 2 AIH
   c. Present in pediatric population and up to 20% of adults in Europe; also present in patients with drug-induced hepatitis
5. Autoantibodies against soluble liver antigen and liver-pancreas antigen (anti-SLA/LP):
   a. Present in 10% to 30% of patients
   b. Associated with higher rate of relapse after corticosteroid therapy
   c. Several studies suggest that patients with anti-SLA/LP have a more severe course

Serum perinuclear anti-neutrophil cytoplasmic antibodies levels are useful for diagnosis of the 10% to 15% of patients with negative ASMA, negative ANA, and low gamma globulin levels.

- Hypoalbuminemia and prolonged prothrombin time with advanced disease
- There is a well-described overlap syndrome with primary biliary cirrhosis (7%), primary sclerosing cholangitis (6%), and autoimmune cholangitis (11%). In patients who do not respond to therapy after 3 mo, consider cholangiographic studies to evaluate for primary sclerosing cholangitis

IMAGING STUDIES

- Ultrasound of liver and biliary tree to rule out obstruction or hepatic mass.
- MR cholangiography if signs of concurrent cholestatic liver disease.
- Cirrhosis secondary to AIH is a risk factor for development of hepatocellular carcinoma (although less so than viral hepatitis). Patients with cirrhosis should get ultrasonography and AFP every 6 mo.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoid alcohol and hepatotoxic medications.
- Liver transplantation is an option for end-stage disease or fulminant hepatic failure.

PHARMACOLOGIC THERAPY

- Initial treatment:
  1. Predniso(lo)ne 0.5 to 1 mg/kg/day followed by addition of azathioprine when bilirubin levels are <6 mg/dl, ideally 2 wk after initiation of steroid treatment. Initial dose 50 mg/day, increase depending on toxicity and response up to 1 to 2 mg/kg. A combination of oral budesonide (6 to 9 mg/day) and azathioprine (1 to 2 mg/kg/day) can be used to induce and maintain remission in patients with non-cirrhotic AIH, with a lower rate of steroid-specific side effects. Treatment of AIH should be response-guided, and regimens should be individualized. Steroids are contraindicated in brittle diabetes mellitus, uncontrolled hypertension, prior steroid intolerance, severe osteopenia, and psychosis. Azathioprine is contraindicated by thiopurine S-methyltransferase (TPMT) deficiency, leukopenia, or thrombocytopenia. Budesonide is contraindicated in cirrhosis because portal systemic shunting and abnormal hepatic metabolism prevent complete hepatic first-pass extraction, reducing therapeutic efficacy and causing systemic steroid side effects.
  2. The azathioprine metabolite, 6-mercaptopurine, has shown promise via small studies in maintaining remission for patients intolerant of azathioprine.

3. Combination therapy allows lower prednisone doses, fewer steroid side effects, and faster normalization of liver function tests.

- The primary goal of therapy in AIH is to achieve remission. The 2015 European Association for the Study of the Liver (EASL) Practice Guideline define biochemical remission as normalization of IgG and aminotransferases. Histologic remission is defined as normal histology or minimal hepatitis (HAI <4 or equivalent) based on the hepatic activity index (HAI). Secondary goals of therapy are the prevention of progression of fibrosis to cirrhosis and reversion of cirrhosis to a lower stage of fibrosis, which has been documented.
- Indications for treatment:
  1. Advanced fibrosis/cirrhosis
  2. Active disease (HAI >4) on histology
- Treatment not indicated:
  1. Mild disease with ALT <3× ULN; HAI <4 and no advanced fibrosis (in these cases treatment is optional)
  2. Patients can be monitored every 3 months with laboratory tests (ALT, IgG)
- Evaluation of treatment response:
  1. Goals are the absence of symptoms, normalization of liver function tests, and absence of inflammatory activity on liver biopsy. Generally, this is a steroid-responsive condition, but up to 20% do not respond.
  2. Patients whose transaminase levels normalize may continue to have ongoing active hepatitis involving inflammation and fibrosis.
  3. Histologic improvement may lag behind clinical and laboratory improvement by as much as 6 mo. Because of this, repeat liver biopsy should be considered after normalization of transaminase levels and before stopping treatment. A review of AIH studies between 1972 and 2013 shows that hepatic fibrosis improves in 53% to 57% of cases and that progressive fibrosis is slowed or prevented in 79% of patients.
  4. After initial remission is achieved and azathioprine has been added, steroid taper can be initiated as long as liver tests are normal. About 50% to 86% of patients will relapse after this and require long-term maintenance medications.
  5. Complete normalization on biopsy is associated with a 15% to 20% risk of relapse, whereas persistent interface hepatitis is associated with a 90% risk of relapse. Do not attempt multiple treatment withdrawals. The risk of developing cirrhosis with single relapse is 9.5%, whereas multiple relapses are associated with 37.5% risk of developing cirrhosis. The patient with sustained remission has a risk of cirrhosis of 4.5%.
  6. Suboptimal response: A failure to adequate response should lead to a reconsideration of the diagnosis or re-evaluation of adherence to treatment. In patients with suboptimal response despite reconfirmation of diagnosis and adherence, doses of prednisolone and azathioprine should be increased, or alternative medications should be used. Patients with acute severe AIH should be treated with high doses of intravenous corticosteroids (>1 mg/kg) as early as possible. Lack of improvement within 7 days should lead to consideration of emergency liver transplantation.

DISPOSITION

- Long-term treatment may be necessary for sustained remission in individuals who relapse after initial immunosuppression withdrawal and in partial responders.
- 65% of patients achieve remission by 18 mo; 80% achieve remission by 3 yr.
- Approximately 10% to 15% of patients do not respond to conventional therapy. The risk factors for nonresponse include presence of underlying cirrhosis, younger age, or longer duration of disease, HLA-B8 or DR3. High-dose therapy can achieve remission in 70%: Prednisone 60 mg or dual therapy with prednisone 30 mg and AZA 150 mg. Other alternatives such as mycophenolate, the calcineurin inhibitors (CNIs), tacrolimus (TAC) and cyclosporine (CSA), sirolimus (SIR), everolimus (EVR), rituximab, and infliximab, have been used successfully. However, none of the alternative therapies has been studied in multicenter, randomized, controlled trials.
- Orthotopic liver transplantation (OLT) is a lifesaving option for AIH patients with acute liver failure, decompensated cirrhosis, or HCC. Allograft and patient survival are excellent; however, AIH recurs in the allograft in a minority (25% probability in first 5 yr, 50% in 10 yr).

REFERRAL

Patients with advanced cirrhosis or who progress to end-stage liver disease are candidates for liver transplantation and should be referred to appropriate medical centers that provide liver transplantation services.

PEARLS & CONSIDERATIONS

COMMENTS

- ANA and SMA are observed together in 60% of cases. Serum titers >1:40 suggest autoimmune hepatitis.
- A variety of autoimmune conditions can be seen in association with autoimmune hepatitis, including thyroiditis, Graves disease, ulcerative colitis, rheumatoid arthritis, uveitis, pernicious anemia, Sjögren syndrome, mixed connective tissue disease, CREST syndrome, and vitiligo.
- Variant forms of autoimmune hepatitis (overlap syndrome) have clinical and serologic findings of autoimmune hepatitis plus features of other forms of chronic liver disease such as PBC or PSC.

Autoimmune Hepatitis (Patient Information)

AUTHORS: **Jaspreet S. Suri, MD,** and **Andreea M. Catana, MD**

TABLE E2 Serologic Markers of Autoimmune Hepatitis

Autoantibodies	Antigenic Target	Clinical Implications
ANA	Multiple nuclear antigens	Type 1 AIH Variably expressed with SMA
SMA	Actin (F and G) Nonactin components (14%)	Type 1 AIH Variably expressed with ANA
Anti-LKM1	CYP2D6 (main epitope, 193-212 amino acid sequence)	Type 2 AIH Usually exclusive of ANA, SMA Mainly in children Associated with HLA DRB1*07
Anti-SLA	Transfer ribonucleoprotein ($tRNP^{(ser)sec}$); renamed Sep [O-phosphoserine] tRNA:Sec [selenocysteine] tRNA synthase (SEPSECS)	Diagnostic specificity of 99% for AIH Associated with HLA DRB1*0301 and anti-Ro/SSA Of prognostic value (severe disease, relapse, treatment dependence)
Atypical pANCA	Nuclear lamina proteins	Present in 50%-92% of type 1 AIH Absent in type 2 AIH Associated with PSC and UC
Anti-actin	Actin (F and G)	Present in 86% of AIH with SMA Of possible prognostic value (assay dependent) Double reactivities to actin and α-actinin are associated with severe disease
Anti-asialoglycoprotein receptor	Asialoglycoprotein receptor (recombinant H1 subunit in investigational EIA)	Associated with histologic activity and relapse after drug withdrawal Disappears with effective treatment
Anti-liver cytosol type 1	Formiminotransferase cyclodeaminase	Frequently concurrent with anti-LKM1 (32%) Mainly in young patients (≤20 yr of age) Associated with concurrent immune diseases, severe liver inflammation, and rapid progression to cirrhosis Rare in North American patients

Anti-LKM1, Antibodies to liver kidney microsome type 1; *anti-SLA,* antibodies to soluble liver antigen; *AIH,* autoimmune hepatitis; *ANA,* antinuclear antibodies; *CYP2D6,* cytochrome P450 2D6; *EIA,* enzyme immunoassay; *pANCA,* perinuclear antineutrophil cytoplasmic antibodies; *PSC,* primary sclerosing cholangitis; *Ro/SSA,* ribonucleoprotein/Sjögren syndrome A protein; *SMA,* smooth muscle antibodies.

Autosomal Dominant Polycystic Kidney Disease (ADPKD)

BASIC INFORMATION

DEFINITION

Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease. ADPKD is a systemic, inherited disorder due to mutations in either the *PKD1* or *PKD2* genes. These mutations lead to continual, fluid-filled cyst formation and growth in multiple organs including the kidneys, liver, and pancreas. ADPKD is also associated with multiple gastrointestinal and cardiovascular abnormalities.

SYNONYMS

Polycystic kidney disease
ADPKD
PKD

ICD-10CM CODES

Q61.3	Polycystic kidney, unspecified
Q61.2	Polycystic kidney, adult type
Q61.19	Other polycystic kidney, infantile type
Z82.71	Family history of polycystic kidney

EPIDEMIOLOGY & DEMOGRAPHICS

- Most common, single, genetic cause of chronic kidney disease (CKD).
- Mendelian dominant disorder.
- Affects all ethnic groups equally worldwide.
- Autosomal dominant polycystic kidney disease type 1: Approximately 78% of affected individuals with genetically resolved cases have a gene mutation on chromosome 16 (*PKD1* gene).
- Autosomal dominant polycystic kidney disease type 2: Approximately 15% of affected individuals with genetically resolved cases have a gene mutation located on chromosome 4 (*PKD2* gene).
- Autosomal dominant polycystic kidney disease type 3: An increasing number of cases have been linked to mutations of the alpha glucosidase II gene (*GANAB*) located on chromosome 11q12.3.
- Each child of an affected parent has a 50% chance of inheriting the mutated gene.
- The disease has 100% penetrance and does not skip generations.

INCIDENCE: ADPKD prevalence was reported to be between 1 in 400 and 1 in 1000 live births based on earlier studies from Denmark and U.S. ADPKD prevalence reported in subsequent studies from Europe and Japan is between 1 in 2525 and 1 in 4000.

GENETICS: The bulk of ADPKD cases stem from a mutation in the *PKD1* gene, located on the short arm of chromosome 16. The gene encoding polycystin-1 (PC1) plays a vital role in cell-cell and cell-matrix interactions and primary ciliary function. Mutations in the *PKD1* gene lead to altered differentiation of epithelial cells and the abnormal phenotypic expression that characterizes ADPKD. ADPKD is less commonly caused by a mutation in the *PKD2* gene located on chromosome 4. The *PKD2* gene encodes the protein polycystin-2 (PC2) that is involved in intracellular calcium signaling. *PKD2* patients typically have milder disease with later onset of end-stage renal disease (ESRD), death, and hypertension. Polycystins 1 and 2 form a single functional protein complex via interactions of their intracellular carboxy termini. Consequently, a mutation of either the *PKD1* or *PKD2* gene produces a similar phenotype that cannot be distinguished.

ADPKD is also caused by mutations in the *GANAB* gene in up to 3% of ADPKD patients. This gene is located on chromosome 11q12.3 and is expressed in kidney and liver. The gene product plays an important role in PC1 maturation. Typically, ADPKD patients with *GANAB* gene mutations have mild PKD and mild-to-severe polycystic liver disease.

CLINICAL PRESENTATION

ADPKD is a systemic disorder, and symptoms relate primarily to kidney cyst burden and extrarenal involvement, including polycystic liver disease and vascular complications (Fig. E1). Total kidney volume (TKV) and cyst volume in ADPKD increase exponentially over time in patients with ADPKD.

RENAL MANIFESTATIONS

Many patients with ADPKD are relatively asymptomatic, particularly in the first three decades of life. A diagnosis of ADPKD is typically established by identification of an afflicted family member with asymptomatic screening (approximately 40% of cases), or renal imaging performed for clinical indications. Patients may present with gross hematuria, flank mass/pain, polyuria/nocturia, fever due to a kidney or lower urinary tract infection, nephrolithiasis, or blood pressure elevation. Typically more than half of patients will have one of these complications by age 30. Importantly, all of these complications are manifested through increased cyst burden or TKV.

Gross hematuria occurs in 35% to 50% of patients with ADPKD and is associated with greater TKV. Gross hematuria may also result from spontaneous or traumatic cyst rupture into the collecting system and more typically microscopic hematuria is secondary to nephrolithiasis. Nephrolithiasis occurs in approximately 27% of ADPKD patients, due in part to low levels of urinary citrate, increased serum uric acid concentrations, and alterations in calcium oxalate and calcium phosphate supersaturation. Nephrolithiasis may present with acute flank pain with radiation to the groin, often with a fever and hematuria, commonly microscopic.

Polyuria, nocturia, and increased thirst in ADPKD occur from impaired urinary concentrating ability and increase in circulating vasopressin levels.

Proteinuria is not a common feature of ADPKD and is usually less than 1 g/day. However, the presence of detectable proteinuria and microalbuminuria is correlated with increased TKV and more severe kidney disease.

Lower urinary tract infections are common in patients with ADPKD but may not occur more frequently than in the general population. Renal cyst infections are specific to ADPKD, and patients typically present with localized flank pain, fevers, and nausea and vomiting, similar to pyelonephritis.

Acute flank pain can be caused by a kidney stone, kidney or liver cyst rupture, or hemorrhage. Chronic pain is typically due to enlarged kidneys, unilaterally or bilaterally.

CARDIAC MANIFESTATIONS

Hypertension occurs in 60% of patients with ADPKD before any substantial decline in kidney function, and appears earlier in males than in females. Hypertension in ADPKD is due to upregulation of the renin-angiotensin-aldosterone system (RAAS). Hypertension is a predictor of worse renal outcome and is associated with cardiovascular morbidity and mortality. Cardiac valvular abnormalities occur in 25% to 30% of patients and include mitral valve prolapse and aortic regurgitation.

EXTRARENAL MANIFESTATIONS

- The prevalence of intracranial aneurysms (ICAs) in ADPKD is approximately 5% and increases to as high as 20% in patients who have a first-degree relative with a known intracranial aneurysm rupture.
- Rupture of an ICA is a serious complication of PKD and may produce significant permanent morbidity or death. Routine screening for ICA is recommended for patients with a family history of ICA or intracerebral bleed. Recently, smoking exposure and the presence of hypertension have been shown to associate with ICA in ADPKD. Screening is also recommended for ADPKD patients before major elective surgery, patients employed in high-risk occupations that would potentially place the lives of others at risk from a ruptured aneurysm (e.g., pilots, heavy machine operators), or patients with warning symptoms such as a sentinel headache.
- In addition to kidney cysts, cysts can develop in the liver, pancreas, and seminal vesicles. Hepatic cysts are common and occur in nearly 85% of ADPKD patients by age 30 yr. Hepatic cysts represent the most common extrarenal manifestation of ADPKD. Liver cystic disease is typically asymptomatic and develops slightly later than kidney cysts in ADPKD. However, hepatic cysts can cause serious complications including pain, infection, bleeding, and biliary obstruction. Liver cysts continue to grow and expand after patients reach kidney failure.
- Colonic diverticula and abdominal or inguinal hernias occur more frequently in ADPKD patients.
- Seminal vesical cysts have been reported to occur in up to 40% of men with ADPKD, but are not associated with reduced fertility.
- Patients with ADPKD may be at an increased risk of developing liver, colon, and kidney cancer. However, there is sparse evidence on which to recommend any change in current cancer-screening guidelines for ADPKD patients.

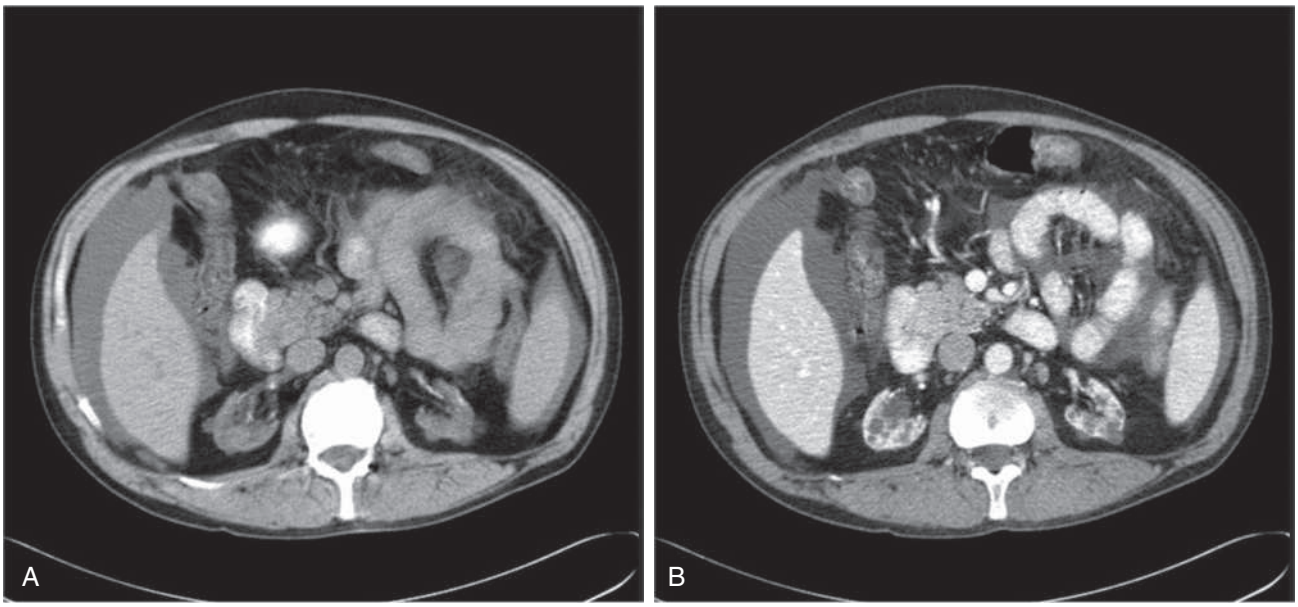

FIG. 3 Adulthood-acquired polycystic kidney disease: computed tomography scan, axial image without contrast material **(A),** and axial image after administration of contrast material **(B).** The kidneys are small bilaterally with multiple 1-cm cysts primarily in the cortex. (From Skorecki K et al: *Brenner & Rector's the kidney*, ed 10, Philadelphia, 2016, Elsevier.)

NATURAL HISTORY

- Patients with *PKD1* gene mutations have faster disease progression than patients with *PKD2* gene mutations. The median age of onset of ESRD is 54 yr in *PKD1* gene patients and 74 yr in *PKD2* patients.
- Patients with truncating *PKD1* gene mutations have faster disease progression than patients with nontruncating *PKD1* gene mutations. The median age of onset of ESRD is 55 yr in *PKD1* patients with truncating mutations and 67 yr in patients with nontruncating mutations.
- Other clinical risk factors associated with progressive kidney disease in ADPKD include male sex, onset of hypertension before 35 yr of age, gross hematuria before age 40, presence of proteinuria or microalbuminuria, increased urinary sodium excretion, and increased circulatory low-density lipoprotein cholesterol levels. However, all of these risk factors are mediated through cyst burden or TKV.
- Data from the Consortium of Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP) indicate that a decline in renal blood flow and increases in TKV and cyst volume are strong predictors of future renal functional decline and progression to CKD stage 3. A baseline height-adjusted TKV (htTKV) of 600 ml/m predicts the risk of developing CKD stage 3 within 8 yr. Patients with ADPKD may be classified as 1A to 1E based on the Mayo Clinic Imaging Classification of ADPKD (https://www.mayo.edu/research/documents/pkd-center-adpkd-classification/doc-20094754). This classification is based on growth rates estimated from age-based htTKV (<1.5%, 1.5% to 3%, 3% to 4.5%, 4.5% to 6%, >6%/yr). This classification should only be applied to patients previously classified as having typical ADPKD (i.e., large kidneys with extensive cysts scattered throughout both kidneys at ages 15 to 80 yr). Patients in class 1A are at a low risk for renal function decline. Patients in classes 1C to 1E are at a high risk for progressive disease. This classification helps physicians identify patients with severe disease.

Dx DIAGNOSIS

- Ultrasound of the kidneys is the most commonly used imaging modality for screening and diagnosis. It is inexpensive, readily available, noninvasive, and free of radiation. CT and MRI are also used, but typically in the setting of acute complications. CT scans (Fig. E2) and MRI are more sensitive than ultrasound, with cyst detection at <1 cm in size.
- The following diagnostic criteria are used for diagnosis of ADPKD in asymptomatic individuals at risk for development of ADPKD (i.e., those with positive family history of ADPKD):
  1. Individuals 15 to 39 yr of age: At least three unilateral or bilateral kidney cysts.
  2. Individuals 40 to 59 yr of age: At least two cysts in each kidney.
  3. Individuals older than 60 yr of age: At least four cysts in each kidney.
- With no family history of ADPKD, there is no definitive number of cysts and/or cyst location that provides an unequivocal diagnosis. The diagnosis is strongly suspected when multiple and bilateral kidney cysts are present along with hepatic cysts.
- Genetic testing can be done to diagnose ADPKD when imaging results are equivocal and when a definitive diagnosis is required in a young individual such as a potential living donor.

DIFFERENTIAL DIAGNOSIS

- Multiple benign simple cysts
- Autosomal recessive PKD
- Familial juvenile nephronophthisis
- Medullary cystic or UMOD (uromodulin) disease
- Medullary sponge kidney
- Tuberous sclerosis
- von Hippel-Lindau syndrome
- Acquired cystic kidney disease (Fig. 3)
- Table 1 compares renal cystic diseases

LABORATORY TESTS

- Hemoglobin and hematocrit may be elevated because of increased erythropoietin production but are typically similar to levels in other patients with CKD.
- Urinalysis can show microscopic hematuria and proteinuria (rarely >1 g per day).
- With decreased kidney function, blood urea nitrogen and creatinine are elevated.
- Platelet counts can be mildly reduced in patients with extensive polycystic liver disease.
- Metabolic acidosis, hyperparathyroidism, and hyperphosphatemia are all associated with CKD in ADPKD.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Dietary intervention should be prescribed to all ADPKD patients.

- Restriction of dietary salt (<2 g sodium per day) and calories is recommended. Post hoc analysis of the HALT-PKD trial in which all patients were instructed to follow a sodium-restricted diet (2.4 g per day) showed that greater urine sodium excretion was

TABLE 1 Comparison of Renal Cystic Diseases

	ADPKD	Tuberous Sclerosis	ARPKD	MCDK	Simple Cyst
Inheritance	AD	AD	AR	None	None
Distribution	Bilateral unequal	Bilateral	Bilateral equal	Unilateral or bilateral	Unilateral
Kidney size	Normal or large	Normal or large	Very large (>90th percentile)	Small or large	Normal
Extrarenal manifestations	Cysts in the liver, spleen, pancreas	Cardiac rhabdomyomas, intracranial tubers	Congenital hepatic fibrosis	None	None
Age at presentation	Third decade	Often <18 mo	Neonate and childhood	Antenatal, rare in childhood	Onset in adult life
Cyst size	Visible cysts of variable size	Similar to ADPKD, ± angiomyolipomas	Generally small	Large then often involute	Variable
Diagnosis	US, genetic	US, cardiac echo, cranial MRI	US, IVU, liver biopsy	US, MAG3	US, IVU
Malignancy risk	No	Yes	No	Rare	No

associated with kidney growth and faster renal function decline.
- Cyclic adenosine monophosphate (cAMP) contributes to cyst formation and growth in ADPKD. Circulating vasopressin stimulates renal cAMP production. Increasing water intake to greater than 3 L per day can suppress vasopressin. Consequently, increasing water intake is recommended for all ADPKD patients with preserved renal function. However, serum sodium should be monitored carefully in patients with advanced CKD because these individuals are vulnerable to the development of hyponatremia.

CHRONIC GENERAL Rx

- Data from the HALT-PKD trial showed that in young individuals with preserved kidney function, strict BP control of <110/75 mm Hg was associated with slower increase in TKV, reduced urinary albumin excretion, and a greater reduction of left ventricular mass index.
- For all ADPKD patients, the goal BP is <130/80 mm Hg. For young, healthy patients with ADPKD and with intact kidney function, the goal BP target can be <110/75 mm Hg.
- ACE inhibitors or angiotensin II receptor blockers are the drugs of first drug for treatment of hypertension.
- Hyperlipidemia should be aggressively treated, and LDL-cholesterol targets are <80 mg/dl.
- Pravastatin was found to have a beneficial effect on htTKV, left ventricular mass index, and urinary albumin excretion in a randomized, double-blind, placebo-controlled phase 2 trial involving 91 children and young adults with ADPKD. A 23% change in htTKV was observed in the pravastatin group compared to 31% in the placebo group.
- Statin therapy did not show any benefit in a post hoc analysis of the HALT-PKD trials. However, this study was not randomized, different statin drugs and doses were used, and only a small number of statin users were in that study.
- Use of statins in the management of patients with ADPKD is a personal physician choice. A larger, randomized controlled trial is required to study the effect of statins on cyst growth.
- Patients who progress to ESRD require renal replacement therapy. Both peritoneal dialysis and hemodialysis can be used as a bridge to kidney transplantation.

The complication rates after nephrectomy are higher with pre–kidney transplant nephrectomy compared with posttransplant nephrectomy. Blood transfusion during pre–kidney transplant nephrectomy my cause allosensitization and can delay kidney transplantation evaluation. Consequently, routine pre–kidney transplant nephrectomy is not recommended. Pre–kidney transplant unilateral or bilateral nephrectomy is recommended only in select patients with recurrent infections, recurrent or severe bleeding, renal cell carcinoma, and significant kidney enlargement causing limitation of daily activities, and malnutrition.

ACUTE GENERAL Rx

- The treatment of gross hematuria is typically supportive with bed rest, hydration, and analgesics. Antihypertensive medications should be stopped during this time.
- Extracorporeal shock wave lithotripsy (ESWL) has been used in patients with small obstructing kidney stones (<2 cm diameter) in the renal pelvis or calyces. Percutaneous nephrolithotomy is another potential option.
- Infections are treated with antibiotics that penetrate cysts, such as fluoroquinolones, trimethoprim/sulfamethoxazole, vancomycin, and chloramphenicol.
- New therapies affecting cyst growth
- Tolvaptan
- In a phase 3, double-blind, placebo-controlled, randomized trial (TEMPO 3:4 trial) involving 1450 patients with PKD and preserved kidney function, the vasopressin-receptor 2 antagonist, tolvaptan, significantly decreased kidney volume and slowed the decline in kidney function. The benefits of tolvaptan on TKV rate of increase and decline of kidney function are greater in patients with increased albuminuria. The benefits of tolvaptan on TKV were seen across CKD stages 1 to 3.
- The effect of tolvaptan on delaying renal function decline was maintained for additional 2 yr in an extension study TEMPO 4:4 trial, where all TEMPO 3:4 participants were offered treatment with tolvaptan for an additional 2 yr.
- A second tolvaptan trial (REPRISE) was conducted and examined the safety and efficacy of tolvaptan in patients with more advanced ADPKD. This was a 12-mo phase III, randomized withdrawal, multicenter, placebo-controlled double-blind trial that included 1370 patients with eGFR between 25 and 65 ml/min/1.73 m^2. Tolvaptan-treated patients demonstrated a reduction in eGFR decline of 35% compared to placebo. Those receiving placebo lost 3.61 ml/min per 1.73 m^2 per yr. Tolvaptan-treated patients demonstrated an eGFR decline of 2.34 ml/min per 1.73 m^2 per yr, a difference of 1.27 ml/min per 1.73 m^2 per yr, which was statistically significant. The beneficial effect of tolvaptan on renal function decline was established in all subgroups (<55 yr of age, men and women, and patients with CKD stages 3A, 3B, and 4). This beneficial effect was not observed in patients older than 55 yr of age. However, firm conclusions cannot be made in this subgroup due to relatively smaller numbers.
- Based on the above studies, the FDA approved tolvaptan for treatment of ADPKD in adult patients at risk for rapidly progressing ADPKD on April 24, 2018.
- Patients at Mayo classes 1C–1E levels of cyst burden (faster rates of cyst growth) likely have rapidly progressive disease and should be considered for treatment with tolvaptan. Treated individuals may experience polyuria, nocturia, abnormally frequent urination, and polydipsia. Post-hoc analysis of TEMPO 3:4 and TEMPO 4:4 trials suggests that the drug effects are more pronounced early after drug initiation and in patients with better kidney function. Appropriate hydration

is essential to prevent thirst, dehydration, and hypernatremia.

A minor reversible eGFR reduction of 5% to 10% is anticipated after initiation of tolvaptan. Tolvaptan dose reduction or withholding of the agent is recommended if a significant decline of GFR of >20% is observed. Renal function testing should be carried out 2 and 4 wk after initiation, then monthly for the first 18 mo, and every 3 mo thereafter. To ensure that patients are maintaining hydration while on tolvaptan, plasma sodium concentration measurements must be obtained.

- Another important adverse event associated with tolvaptan is liver toxicity. Two patients in the TEMPO 3:4 trial and 1 patient in the TEMPO 4:4 trial developed serious drug-induced liver injury. In the REPRISE trial, liver adverse effects were greater in the tolvaptan group compared to placebo (5.6% vs. 1.2%). Because of the risks of serious liver injury, tolvaptan prescriptions are only available through a restricted distribution program called the Risk Evaluation and Mitigation Strategy (REMS). Under this program, liver function testing is done before initiation of treatment, at 2 wk and 4 wk after initiation, then monthly for the first 18 mo, and every 3 mo thereafter.

Other therapies affecting cyst growth:

- A small trial involving the somatostatin analogue, octreotide long-acting repeatable depot, showed that there was significantly less increase in TKV in the octreotide group compared with placebo. Another randomized phase III trial involving 100 ADPKD patients with eGFRs between 15 and 40 ml/min per 1.73 m^2 demonstrated that a 3-yr treatment with octreotide long-acting release (octreotide LAR) significantly slowed kidney volume growth. Octreotide LAR did not affect GFR decline compared with placebo. However, fewer patients in the octreotide group progressed to the combined end point of doubling of serum creatinine or ESRD when compared with placebo (19% vs. 43%).
- In a phase 2, randomized, double-blind, placebo-controlled study, the oral tyrosine kinase inhibitor bosutinib reduced kidney growth and preserved kidney function. However, medication-related adverse events (diarrhea, rash, and pancreatitis) and acute declines in kidney function have limited development of this agent.
- Two randomized, double-blind trials investigating the mammalian target of rapamycin inhibitors, sirolimus and everolimus, did not show any effect on renal function in these patients. The shorter duration of these trials and inadequate dosing of the medications may have affected the outcome.

REFERRAL

- Patients with ADPKD should be referred at time of diagnosis to a nephrologist for ongoing care. Urology can also be consulted in patients with nephrolithiasis for recurrent episodes of gross hematuria, or consideration for nephrectomy before transplantation.

Genetic counseling should be offered if patients plan to start a family or are considering having their children undergo screening examinations. Individuals at risk for ADPKD should undergo pretest and posttest counseling if they are found to have ADPKD.

PEARLS & CONSIDERATIONS

- ADPKD is the most common, single, genetic cause of CKD.
- TKV increases exponentially over time, and the increase in TKV is a strong predictor of future kidney functional decline.
- Increasing water intake to >3 L per day is recommended in patients with ADPKD and preserved kidney function.
- Tolvaptan is recommended for patients with rapidly progressing ADPKD.
- Strict blood pressure control is recommended for all ADPKD patients.

BASIC INFORMATION

DEFINITION

Cerebral arteriovenous malformations (AVMs) are congenital vascular lesions that are characterized by blood flow from high-pressure arterial vessels directly into thin-walled veins without passing through an intervening capillary/venule system (Fig. 1).

SYNONYMS

Arteriovenous malformations of the brain
AVM
Brain AVM

ICD-10CM CODE
Q28.2 Arteriovenous malformations of cerebral vessels

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:
- Detection rates in large prospective studies range from 1.1 to 1.4 per 100,000 person-yr.
- Incidence of hemorrhage, the most common and often most clinically dangerous presentation, is estimated to be 2% to 4% per yr.

PREVALENCE: Estimated about 1.3 per 100,000
PREDOMINANT SEX AND AGE:
- There is a slight male preponderance; studies of varying populations show 1.04:1 to 1.2:1 male:female ratio.
- Peak age at time of hemorrhage occurrence is about 20 yr, but it can occur in younger and older patients.

RISK FACTORS:
- Male sex and presence of HHT are risk factors for AVM.
- The risk of hemorrhage is increased with prior hemorrhage, presence of a single draining vein, and diffuse nidus morphology.

GENETICS:
- Cerebral AVMs are sporadic in most cases.
- AVMs are present in about 20% of cases of Osler-Weber-Rendu syndrome (also known as hereditary hemorrhagic telangiectasia [HHT]), an autosomal dominant disorder that results in abnormal blood vessel formation in the skin, lungs, liver, brain, and other organs.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The most common presentation is hemorrhage; symptoms vary based on location and magnitude of hemorrhage.
- Patients may present with seizures or neurologic deficits related to mass effect of the AVM nidus.
- Headache and pulsatile tinnitus may be present.
- In infants, AVM may present as cyanotic heart failure, macrocephaly, or hydrocephalus.
- A bruit may be auscultated through the scalp or orbit.
- AVMs may also present with associated intracranial aneurysms that occur on distant, unrelated vessels, on a proximal artery that feeds the aneurysm (flow-related aneurysm), or within the AVM nidus itself (intranidal aneurysm). Patients may present with a subarachnoid hemorrhage related to the aneurysm rather than to the AVM.

ETIOLOGY

In most cases, AVMs are congenital abnormalities caused by failure of formation of a capillary bed between embryonic arterial and venous vascular plexuses during the first trimester of gestation; however, de novo sporadic AVMs have been reported.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of cerebral AVMs includes other vascular lesions such as cavernous malformations, dural arteriovenous fistulas, and intracranial aneurysms. Table E1 compares vascular malformations, and Table E2 describes major differences between hemangiomas and vascular malformations.

LABORATORY TESTS

- CBC and basic metabolic panel (BMP) with renal function panel prior to contrast dye administration with CT angiography/cerebral angiogram.
- Prothrombin time/international normalized ratio/partial thromboplastin time (PT/INR/PTT) should be drawn and corrected in the case of bleeding diathesis.

IMAGING STUDIES

- In the acute setting, a CT scan of the head to check for hemorrhage and a CT angiogram of the head for characterization of the lesion may be helpful (although calcification may be present and potentially pose as small acute blood).
- MRI of the brain delineates the nidus and its relationship to surrounding soft tissue structures better than a CT scan; however, in the setting of an acute hemorrhage these details will be obscured.
- Four-vessel cerebral angiogram (arteriogram) is the best study to evaluate AVM. Angiography in multiple projections helps identify the number and location of feeding and draining vessels for treatment planning (Fig. 2). High-resolution images of the nidus may also reveal other irregularities such as aneurysms that often arise given the abnormal histology of the vessel walls and the high-pressure blood flow traversing them.

TREATMENT

Pharmacologic management of seizures with antiepilepsy drugs and of headaches with oral analgesics can provide symptomatic relief.

NONPHARMACOLOGIC THERAPY

- Nonemergent outpatient setting: Cerebral angiogram provides characterization of the lesion. Based on angiographic characteristics, the Spetzler-Martin AVM grading system may be used to help guide treatment. In general, grade 5 AVMs are considered unresectable; they are not treated because the risks of treatment likely outweigh the risk of hemorrhage. Current tools for the treatment of AVMs include surgical resection, radiosurgery, and endovascular embolization (with liquid glues or embolic agents).
- Surgical resection: In low-grade lesions by an experienced neurosurgeon yields a high cure rate (~95% in published studies). Resection should include removal of all of the nidus of the AVM; failure to remove the complete nidus may increase the risk of recurrence. An increasing Spetzler-Martin grading scale increases risk of neurologic complications. Intraoperative imaging techniques such as indocyanine-green in-field angiography and conventional digital subtraction angiography are used to verify complete resection.
- Radiosurgery: Alternative definitive treatment for AVMs. Traditionally employed to treat

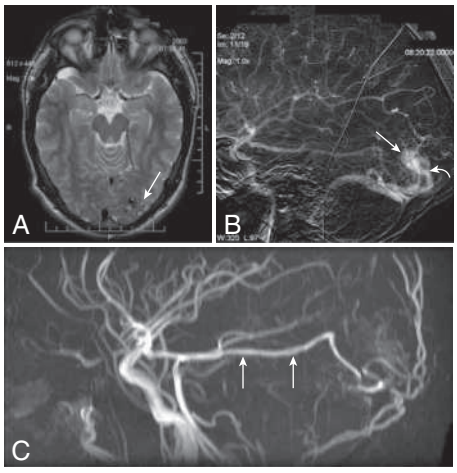

FIG. 1 A 14-year-old child with a left occipital arteriovenous malformation (AVM). A, Magnetic resonance image shows multiple flow voids in the left occipital lobe *(arrow).* **B,** Lateral view from catheter angiogram confirms the presence of an AVM *(arrow)* and early draining veins *(curved arrow).* **C,** Lateral maximum intensity projection image from a magnetic resonance angiogram shows an enlarged posterior cerebral artery branch *(arrows),* which feeds the tangle of abnormal vessels. (From Fuhrman BP et al: *Pediatric critical care,* ed 4, Philadelphia, 2011, WB Saunders.)

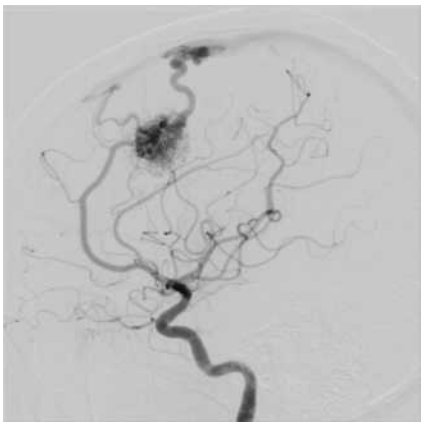

FIG. 2 Arteriovenous malformation of the frontal lobe. The anterior cerebral artery provides primary arterial supply with venous drainage superficially into the superior sagittal sinus.

AVMs in eloquent areas (e.g., brainstem); stereotactic radiosurgery is increasingly used for higher Spetzler-Martin grade AVM. Reported rates of confirmed radiographic obliteration after AVM radiosurgery range from 47% to 90%.

- Endovascular embolization involves transarterial superselective blockage of the AVM. It has become an important adjunctive tool. Currently recommended and approved for use before resection, preoperative embolization can reduce arterial flow and pressure within the AVM, assisting in speed and safety of surgical resection. In addition, embolization may often be used to treat intranidal or flow-related aneurysms in coordination with either resection or radiosurgery. Embolization alone in obliterating an AVM is not routinely recommended.
- Treatment decisions should take into consideration the morbidity associated with the treatment modality versus the risk of future hemorrhage or neurologic deterioration. Disability stemming from intractable seizures or severe headaches may make invasive definitive treatment a more attractive option.
- Acute cerebral hemorrhage: In the case of an acute hemorrhage, airway and breathing must be maintained, with intubation if necessary. Acute neurosurgical intervention for clot evacuation may be warranted. Microsurgical resection of the AVM may or may not be feasible in the acute setting and is controversial.

DISPOSITION

Whether the patient is receiving elective treatment of a known lesion or presenting with an acute hemorrhage, the patient should receive care in a progressive or intensive care unit with experience dealing with cerebrovascular disease. Once the patient is stabilized, appropriate rehabilitation should be arranged.

REFERRAL

- Cerebral AVMs should be managed by a qualified neurosurgeon.
- Referral to radiation medicine for adjuvant radiosurgery should be made when indicated.
- Referral to an interventional radiologist for endovascular treatment may be warranted.
- Treatment in a primary stroke center or other specialized center that offers all treatment modalities is recommended.

PEARLS & CONSIDERATIONS

COMMENTS

- No two AVMs are exactly the same; individualization of treatment decisions is the mainstay. Additionally, many AVMs could be effectively treated through one of several modalities or a combination thereof. Factors such as patient age, overall health status, radiographic characteristics, route of surgical access, and potential morbidities of each treatment modality are vital variables in consideration for treatment. The advisability of intervention for unruptured AVMs remains controversial. In a recent randomized trial comparing medical management with specific interventions to obliterate AVMs (neurosurgery, embolization, radiotherapy, or a combination) the rates of neurological disability were higher in the intervention group than with conservative treatment.[1]
- The annual risk of hemorrhage from a cerebral AVM is approximately 3%, but depending on the clinical and anatomical features of the malformations, the risk may be as low as 1% or as high as 33%. The risk of bleeding is increased if the patient has had previous episodes of bleeding, if there is a berry aneurysm on an artery feeding the AVM, and if there is a restriction of venous drainage from the AVM.[2]

PATIENT & FAMILY EDUCATION

If a patient with a known AVM suffers from acute-onset neurologic deficits or stroke-like symptoms, emergency medical attention is warranted for potential hemorrhage. Presence of AVMs, cerebral or otherwise, in family members should be disclosed to the patient's primary care physician because the presence of a genetic condition predisposing to cerebral AVMs should be considered.

TABLE E1 Vascular Malformations

Type	Example(s)
Capillary	Port-wine stain
Venous	Venous malformation Angiokeratoma circumscriptum (hyperkeratotic venule) Cutis marmorata telangiectasia congenita (congenital phlebectasia)
Arterial	Arteriovenous malformation
Lymphatic	Superficial lymphatic malformation (lymphangioma circumscriptum) Deep lymphatic malformation with macrocysts and/or microcysts (cystic hygroma)

From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, WB Saunders.

TABLE E2 Major Differences Between Hemangiomas and Vascular Malformations

	Hemangiomas	Vascular Malformations (Capillary, Venous, Lymphatic, Arterial, and Arteriovenous, Pure, or Complex-Combined)
Clinical	Variably visible at birth	Usually visible at birth (AVMs may be quiescent)
	Subsequent rapid growth	Growth proportionate to the skin's growth (or slow progression); present lifelong
	Slow, spontaneous involution	
Sex ratio F:M	3:1-5:1; 7:1 in severe cases	1:1
Pathology	Proliferating stage: Hyperplasia of endothelial cells and smooth muscle cell actin–positive cells	Flat endothelium
	Multilaminated basement membrane	Thin basement membrane
	Higher mast cell content in involution	Often irregularly attenuated walls (VM, LM)
Radiology	Fast-flow lesion on Doppler sonography	Slow-flow (CM, LM, VM) or fast-flow (AVM) on Doppler ultrasonography
	Tumoral mass with low voids on MRI	MRI: Hyperintense signal on T2-weighted images when slow-flow (LM, VM); flow voids on T1- and T2-weighted images when fast-flow (AVM)
	Lobular tumor on arteriogram	Arteriography of AVM demonstrates AV shunting
Bone changes	Rarely mass effect with distortion but no invasion	*Slow-flow VM:* Distortion of bones, thinning, underdevelopment *Slow-flow CM:* Hypertrophy *Slow-flow LM:* Distortion, hypertrophy, and invasion of bones *High-flow AVM:* Destruction, rarely extensive lytic lesions *Combined malformations* (e.g., slow-flow [capillary lymphatic venous malformation, Klippel-Trenaunay syndrome] or fast-flow [capillary arteriovenous malformation, Parkes Weber syndrome]): Overgrowth of limb bones, gigantism
Immunohistochemistry on tissue samples	*Proliferating hemangioma:* High expression of PCNA, type IV collagenase, VEGF, urokinase, and bFGF, glucose transporter-1	Lack expression of PCNA, type IV collagenase, urokinase, VEGF, and bFGF
	Involuting hemangioma: High levels of tissue inhibitor of metalloproteinase-1, bFGF	One familial (rare) form of VM linked to a mutated gene on 9p *(VMCM1)*
Hematology	No coagulopathy (Kasabach-Merritt syndrome is a complication of other vascular tumors of infancy, e.g., kaposiform hemangioendothelioma and tufted angioma)	Slow-flow VM, LM, or LVM may have an associated localized intravascular coagulopathy with risk of bleeding (disseminated intravascular coagulation)

AV, Atrioventricular;*AVM,* arteriovenous malformation; *bFGF,* basic fibroblast growth factor; *CM,* capillary malformation/port-wine stain; *F:M,* female:male; *LM,* lymphatic malformation; *LVM,* lymphovenous malformation; *MRI,* magnetic resonance imaging; *PCNA,* proliferating cell nuclear antigen; *VEGF,* vascular endothelial growth factor; *VM,* venous malformation.

Babesiosis PTG

BASIC INFORMATION

DEFINITION

Babesiosis is a tick-transmitted protozoan disease of animals, caused by intraerythrocytic parasites of the genus *Babesia.* Humans are incidentally infected, resulting in a nonspecific febrile illness. The disease can be severe in immunocompromised hosts.

ICD-10CM CODE
B60.0 Babesiosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): From 2011 to 2015 the CDC was notified of 7612 cases of babesiosis. Cases were reported in 27 states, with 94.5% of cases occurring in 7 states (Fig. 1).

PREVALENCE (IN U.S.):

- In areas of high endemicity, seropositivity ranging from 9% (Rhode Island) to 21% (Connecticut)
- Highest number of reported cases in New York

PREDOMINANT SEX: Males (most likely through increased exposure to vectors during recreational or occupational activities)

PREDOMINANT AGE: Severity apparently increasing with age greater than 50 yr or neonate

PEAK INCIDENCE: Spring and summer months, May through September

GENETICS: None known

CONGENITAL INFECTION: Definite evidence of vertical transmission

NEONATAL INFECTION: Many cases of perinatal transmission

BLOOD TRANSFUSION: Many instances. Blood donation screening for antibodies to and DNA from *B. microti* has been shown to significantly decrease the risk of transfusion-transmitted babesiosis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Incubation period is 1 to 4 wk, or 6 to 9 wk, occasionally longer in transfusion-associated disease.
- Gradual onset of irregular fever, chills, diaphoresis, headache, myalgia, arthralgia, fatigue, and dark urine. Symptoms usually begin within 1 mo after tick bite and within 6 mo after transfusion of infected blood products. Fever is the most frequently reported clinical manifestation.
- On physical examination: Petechiae, frank or mild hepatosplenomegaly, and jaundice. Most patients have a normal physical examination.
- Infection with *B. divergens* (Europe) produces a more severe illness with a rapid onset of symptoms and increasing parasitemia progressing to massive intravascular hemolysis and renal failure.

ETIOLOGY

- Vector: Deer tick, *Ixodes scapularis* (also known as *I. dammini*).
  1. Feeds on rodents during the spring and summer while in its larval and nymphal stages and on deer as an adult
  2. Requires a blood meal to mature to each stage, hence human infection
  3. During the warmer months in endemic areas, humans are readily infected while engaging in outdoor activities
  4. Tick must attach for 36 to 72 hours to transmit infection
- *B. microti* and *B. divergens* account for most human infections. Table 1 compares causal agents and clinical manifestations of babesiosis.
- In the U.S., cases caused by *B. microti* are acquired on offshore islands of the northeastern coast, including Nantucket Island, Cape Cod, and Martha's Vineyard in Massachusetts; Block Island in Rhode Island; and Long Island, Fire Island, and Shelter Island in New York; as well as the nearby mainland including Connecticut, Rhode Island, Massachusetts, New York, and New Jersey.
- Sporadic cases reported from California, Georgia, Maryland, Minnesota, Virginia, Wisconsin, and most recently the WA-1 strain from Washington State and the MO-1 strain from Missouri.
- *B. divergens* is implicated in human disease in Europe, where the disease remains rare and predominantly associated with asplenia.
- *B. venatorum* is emerging as an important pathogen in mainland China.
- Majority of cases of *B. microti* are asymptomatic.
- Is transmissible by transfusion of erythrocytes, or through red cell-contaminated platelets.
- Mixed infections (*B. microti* and *Borrelia burgdorferi,* the causative agent of Lyme disease) are estimated to occur in 30% (Rhode Island and Connecticut) to 60% (New York) of cases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Malaria
- Ehrlichiosis
- Leptospirosis
- Salmonellosis, including typhoid fever
- Acute viral hepatitis
- Hemorrhagic fevers
- Subacute bacterial endocarditis

WORKUP

Should be suspected in any febrile patient living or traveling in an endemic area, irrespective of exposure history to ticks or tick bites, especially if asplenic. The hallmark of babesiosis is hemolysis with resulting anemia. Elevated liver enzymes, thrombocytopenia, and acute kidney injury may occur.

LABORATORY TESTS

- The preferred method for diagnosing babesiosis is polymerase chain reaction (PCR) using whole blood specimens.
- In experienced hands, sequential examination of Giemsa stained thin smears is equally effective.

FIG. 1 Reported cases of babesiosis, by patient's county of residence*—33 states, 2015.† *N = 2070; county of residence was known for all but four (<1%) of the 2074 total patients. Each dot represents one case; dots were placed randomly within the patient's county of residence. †Year as reported by the health department. (From Gray EB, Herwaldt BL: Babesiosis Surveillance—United States, 2011-2015. *MMWR Surveill Summ* 2019;68(No. SS-6):1-11. DOI: http://dx.doi.org/10.15585/mmwr.ss6806a1external icon.)

TABLE 1 Causal Agents and Clinical Manifestations of Babesiosis

Babesia Species	Geographic Distribution	Tick Vectors	Animal Reservoirs	Epidemiology	Clinical Manifestations
B. divergens	United Kingdom, Western Europe, Eastern Europe, Sweden, Russia; not reported in United States	*Ixodes ricinus*	Cattle, reindeer	Incubation, 1-4 wk. Occurs during summer months in cattle-raising regions Targets splenectomized or immunocompromised patients primarily	Fulminant course with high case-fatality rate Fever, rigors, headache, myalgia, jaundice, hemoglobinuria, hemolytic anemia, acute renal failure, multiorgan failure
B. microti	Parallels the U.S. Northeast endemic regions for *Borrelia burgdorferi*, especially the islands off New York, Massachusetts, Connecticut, and Rhode Island and focal areas in Connecticut, New Jersey, Wisconsin, and Minnesota	Deer ticks: *Ixodes dammini* and *Ixodes scapularis*	White-footed mouse *(Peromyscus leucopus)*	Incubation, 1-4 wk after tick bites or 4-9 wk after blood transfusions Transmission primarily by nymphal ticks Targets older, not necessarily immunocompromised patients, particularly severe in those immunocompromised by HIV infection, advanced age, coinfections with *B. burgdorferi* Seasonality parallels tick nymph activity; 80% of cases occur from May to August	Often asymptomatic in young, healthy patients Self-limited influenza-like febrile illness with onset of anorexia, malaise, and lethargy followed in 1 wk by high fever, diaphoresis, myalgias; mild splenomegaly and rarely hepatomegaly Later hemolysis, hemolytic anemia, thrombocytopenia, jaundice, acute renal failure, especially in the splenectomized, older adults, or the immunocompromised Complications include ARDS and DIC Case-fatality rate, 5%
MO-1 (a relative or subspecies of *B. divergens*)	Rural Missouri and Kentucky	*Ixodes dentatus* (rabbit tick)	Rabbits, birds	Incubation, 1-4 wk after tick bites Spring to autumn seasonality Targets the splenectomized, like *B. divergens*	Same as above—often asymptomatic, except in the splenectomized, who will develop high parasitemia and multiorgan failure
WA-1 (a relative or subspecies of *B. gibsoni*)	Rural Washington state	Ixodid ticks, including *Ixodes dentatus*	Unknown—wild canids and ungulates suspected	Incubation, 1-4 wk Targets the splenectomized, older adults, immunocompromised, premature infants May be transmitted by blood transfusion	Same as above—often asymptomatic, except in the splenectomized, who will develop high parasitemia and multiorgan failure
CA-1, CA-2, etc. subspecies (relatives or subspecies of mule deer and bighorn sheep *Babesia* species)	U.S. Pacific coast, primarily rural and semirural areas of California	Ixodid ticks	Unknown—mule deer and bighorn sheep suspected	Incubation, 1-4 wk Targets the splenectomized, elderly, immunocompromised, and premature infants	Same as above—often asymptomatic, except in the splenectomized, who will develop high parasitemia and multiorgan failure

ARDS, Acute respiratory distress syndrome; *DIC,* disseminated intravascular coagulation.
From Bennett JE, Dolin R, Blaser MJ: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Saunders.

- Babesial DNA by PCR has comparable sensitivity and specificity to microscopic analysis of thin blood smears. PCR is more sensitive than smears at the onset of infection when parasite load may be minimal.
- Diagnosis achieved serologically by indirect immunofluorescence assay (IFA) is specific for *B. microti.*
  1. Assay is hampered by the inability to distinguish between exposed patients and those who are actively infected.
  2. Immunoglobulin G titer of ≥1:64 is indicative of seropositivity, whereas one ≥1:1024 is considered diagnostic of acute infection. Immunoglobulin M (IgM) titer of 1:64 is considered indicative of acute infection.
  3. IgM indirect immunofluorescent-antibody test may be highly sensitive and specific for diagnosis. IgM titer of 1:64 is considered indicative of acute infection.
- CBC to reveal mild to moderate thrombocytopenia and anemia. The white blood cell (WBC) count may be normal, elevated, or low. Abnormally elevated serum chemistries, including creatinine, liver function profile, lactate dehydrogenase, and indirect and total bilirubin levels; haptoglobin is low.
- Urinalysis to reveal proteinuria and hemoglobinuria.
- Examination of Giemsa- or Wright-stained thin blood films for intraerythrocytic parasites (Fig. 2):
  1. In its classic, though infrequently seen, form a "tetrad" or "Maltese cross" composed of four daughter cells attached by cytoplasmic strands is observed.
  2. More commonly, smaller forms composed of a single chromatin dot are eccentrically located within bluish cytoplasm.
  3. Parasitized erythrocytes may be multiply infected but not enlarged.
  4. Extra-erythrocytic forms may be seen.
  5. Gametocytes are *not* seen; this is a characteristic of malaria.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Supportive care with adequate hydration

ACUTE GENERAL Rx

- In patients with intact spleens: Predominantly asymptomatic or if symptomatic, generally self-limited

- Therapy may be offered to any symptomatic patient. Table 2 summarizes treatment recommendations.
- Therapy is mandatory for the severely ill patient, especially if asplenic, elderly, or immunosuppressed. Combination of atovaquone 750 mg q12h and azithromycin 500 mg on day 1 and 250 mg per day thereafter for 7 to 10 days appears to be as effective as a regimen of clindamycin and quinine with fewer adverse reactions. This is the preferred regimen for mild disease.
- Combination of quinine sulfate 650 mg PO tid plus clindamycin 600 mg PO tid (600 mg parenterally qid) taken for 7 to 10 days. Severely ill patients are hospitalized and treated with clindamycin and quinine or azithromycin plus atovaquone.
- Exchange transfusions in addition to antimicrobial therapy: Successful treatment for severe infections in asplenic patients associated with high levels of *B. microti* or *B. divergens* parasitemia. Exchange transfusion is recommended for patients with >10% parasitemia, but may be considered for any severely ill patient.
- Relapsed and immunocompromised patients may require a longer duration of therapy.

DISPOSITION

Prognosis is usually good and fatal outcomes are rare.

REFERRAL

- For prompt consultation with an infectious disease specialist if the diagnosis is acutely suspected, especially in the asplenic, elderly, or immunocompromised patient
- For hospitalization for the severely ill patient who may require exchange transfusions in addition to antibiotic therapy

PEARLS & CONSIDERATIONS

COMMENTS

- Prevention of babesiosis in asplenic or immunocompromised hosts is best achieved by avoidance of areas where the vector is endemic, especially May through September.
- If residence or travel in endemic areas is unavoidable, advise patients to perform daily cutaneous self-examination, wear light-colored clothing (to facilitate removal of ticks), tuck pants into socks, and apply tick repellent (diethyltoluamide and dimethyl phthalate) to skin or clothing.
- Advise a daily inspection for ticks in family pets (e.g., cats and dogs).

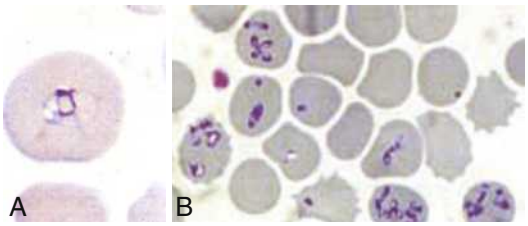

FIG. 2 Babesia parasites. Human infection with species of piroplasm transmitted by the bite of the tick *Ixodes ricinus* infected from cattle is a rare occurrence. Infection in normal people with this piroplasm may give rise to a self-limiting fever and parasitemia, as in the case of infection with the rodent parasite *Babesia microti* on the northeastern seaboard of the United States via the tick *Ixodes scapularis* **(A).** Heavy red-cell infection may develop, however, in splenectomized patients, leading to fatal hemolytic anemia. This patient died as a result of an infection acquired from the cattle parasite *Babesia divergens* in Scotland **(B).** Other species of *Babesia* that occasionally infect humans, for example, the WA1, CA1, and MO1 isolates from the United States, are distinguished by molecular means. (Hoffman R et al: *Hematology, basic principles and practice*, ed 7, Philadelphia, 2018, Elsevier.)

TABLE 2 Treatment of Human Babesiosis

Organism	Severity	Adults	Children
Babesia microti *	Mild†	Atovaquone 750 mg q12h PO plus azithromycin 500 mg PO on day 1 and 250 mg/day PO from day 2 on	Atovaquone 20 mg/kg q12h PO (maximum 750 mg/dose) plus azithromycin 10 mg/kg PO on day 1 (maximum 500 mg/dose) and 5 mg/kg/day PO from day 2 on (maximum 250 mg/dose)
	Severe‡,§	Clindamycin 300-600 mg q6h IV or 600 mg q8h PO plus quinine 650 mg q8h PO	Clindamycin 7-10 mg/kg q6-8h IV or 7-10 mg/kg q6-8h PO (maximum 600 mg/dose) plus quinine 8 mg/kg q8h PO (maximum 650 mg/dose)
*Babesia divergens**		Immediate complete RBC exchange transfusion plus clindamycin 600 mg q6-8h IV plus quinine 650 mg q8h PO	Immediate complete RBC exchange transfusion plus clindamycin 7-10 mg/kg q6-8h IV (maximum 600 mg/dose) plus quinine 8 mg/kg q8h PO (maximum 650 mg/dose)

IV, Intravenously; *PO,* orally; *RBC,* red blood cell.
NOTE: Monitor patients on quinine with electrocardiography; monitor quinine serum levels in the setting of hepatic or renal disease.
*Treatment for 7 to 10 days, but duration may vary.
†Atovaquone (750 mg twice daily) combined with higher doses of azithromycin (600 to 1000 mg/day) has been used in immunocompromised patients. With this regimen, symptoms and parasitemia resolve faster.
‡Consider partial or complete RBC exchange transfusion in cases of high-grade parasitemia (≥10%), severe anemia (<10 g/dl), or pulmonary, renal, or hepatic compromise. Even when parasitemia is less than 10%, consider exchange transfusion if acute respiratory distress syndrome or syndrome resembling a systemic inflammatory response syndrome is present.
§In asplenic individuals and in immunocompromised patients, persistent or relapsing babesiosis should be treated for at least 6 wk, including 2 wk during which parasites are no longer detected.
From Bennet et al: *Principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Elsevier.

- Infection with *B. divergens,* especially in the asplenic patient, is often fatal.
- Concurrent cases of babesiosis and Lyme disease, anaplasma, *Borrelia miyamotoi*, and Powassan virus have been documented—check for combined infection in severely ill patients.
- A combination of clindamycin and quinine has been successfully used to treat babesiosis during the third trimester of pregnancy without incurring apparent adverse effect on the fetus.
- In 2011 the CDC added babesiosis to the list of nationally notifiable diseases.
- Tick avoidance is paramount in prevention of babesiosis.

Baker Cyst (PTG)

BASIC INFORMATION

DEFINITION

Baker cyst is a fluid-filled popliteal bursa located along the medial border of the popliteal fossa. It is an extension of the semimembranosus bursa posteriorly (see Fig. E1).

SYNONYM

Popliteal synovial cyst

ICD-10CM CODES

M71.2	Synovial cyst of popliteal space [Baker], unspecified knee
M71.21	Synovial cyst of popliteal space [Baker], right knee
M71.22	Synovial cyst of popliteal space [Baker], left knee

EPIDEMIOLOGY & DEMOGRAPHICS

- Most are asymptomatic and incidentally found on imaging exams.
- Occurs at all ages, most commonly between age 35 to 70 yr, increasing with age.
- The prevalence of popliteal cysts varies based on the imaging technique used and the age of the patient population.
- Between 2% and 6% of all patients believed to have clinical deep venous thrombosis (DVT) have symptomatic Baker cysts.
- Approximately 5% to 40% of MRIs performed for osteoarthritis or internal derangement reveal popliteal cysts.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms associated with associated joint pathology (knee swelling or stiffness)
- Pain in the popliteal space
- Leg edema
- Prominence of the popliteal fossa
- Decreased range of motion of the knee
- Locking of the knee
- Foucher sign: The cyst becomes hard with knee extension and soft with knee flexion
- Neuropathic lancinating pains radiating from the knee down the back of the leg

FIG. E1 Baker cyst is an extension of the semimembranosus bursa posteriorly. This bursa is often connected with a joint cavity. (From Marx J: *Rosen's emergency medicine: concepts and clinical practice,* ed 6, Philadelphia, 2006, Saunders.)

- Pain or discomfort with prolonged standing and hyperflexion of the knee
- Presence of associated DVT

ETIOLOGY

- Believed to be fluid distention of bursal sac separating semimembranous tendon from medial head of gastrocnemius
- May represent a true cyst but more often a degenerative or inflammatory joint disease or injury; they usually communicate with adjacent knee joint space. Thus, a Baker cyst usually denotes increased intraarticular pressure from underlying joint disease. Sequestration of synovial fluid in the popliteal fossa can result from a valve-like effect between joint space and cyst controlled by gastrocnemius-semimembranosus muscle changes with knee flexion and extension
- In children, popliteal cysts are usually a primary process arising from the gastrocnemius-semimembranosus bursa without direct communication with the joint space
- In adults, Baker cysts are usually associated with pathologic changes of the knee joint, such as the following:
  1. Rheumatoid arthritis (RA)
  2. Osteoarthritis of the knee
  3. Meniscal tears
  4. Patellofemoral chondromalacia
  5. Fracture
  6. Gout
  7. Pseudogout
  8. Infection (tuberculosis)

DIAGNOSIS

Baker cyst frequently mimics DVT and is sometimes referred to as *pseudothrombophlebitis syndrome.*

DIFFERENTIAL DIAGNOSIS

- DVT
- Popliteal artery aneurysm
- Abscess
- Tumor (sarcomas/lymphomas)
- Lymphadenopathy
- Varicosity
- Synovial or ganglion cysts

WORKUP

The diagnosis can be made by physical examination alone. However, anyone suspected of having a popliteal cyst should undergo imaging studies to exclude other causes.

LABORATORY TESTS

Blood tests are not specific.

IMAGING STUDIES

- Plain radiographs (anteroposterior and lateral views) may show calcification in a solid tumor or in the posterior meniscal area.
- Ultrasound (Fig. E2) is safe, portable, and cost effective and excludes other clinically important causes of popliteal fossa pathology, including DVT.

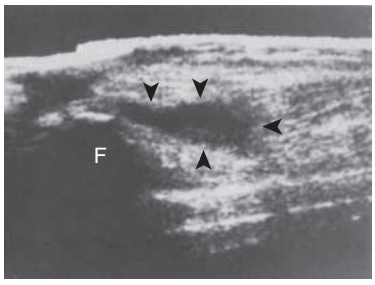

FIG. E2 Sonography of a popliteal cyst. Sagittal sonographic section through the popliteal space in this patient demonstrates a sonolucent fluid collection *(arrowheads)* posterior and inferior to the medial femoral condyle *(F).* (From DeLee D, Drez D [eds]: *DeLee and Drez's orthopaedic sports medicine,* ed 2, Philadelphia, 2003, Saunders.)

- MRI if internal derangement is suspected, surgery being considered, or diagnosis unclear after ultrasound.

TREATMENT

Asymptomatic cysts found incidentally do not require treatment.

NONPHARMACOLOGIC THERAPY

- Rest
- Strenuous activity avoidance
- Knee immobilization sometimes necessary

ACUTE GENERAL Rx

- NSAIDs can be used to treat underlying joint pathology (RA, gout, and pseudogout).
- Arthrocentesis with intraarticular injection or injection of the cyst (Fig. E3) with corticosteroids (triamcinolone acetonide 40 mg).

CHRONIC Rx

- The majority of Baker cysts are successfully treated conservatively
- If refractory symptoms, surgical procedures addressing the underlying cause include:
  1. Arthroscopic surgery to remove loose cartilaginous fragment
  2. Partial or total meniscectomy
  3. Open excision of the cyst

DISPOSITION

- Baker cysts may spontaneously resolve without treatment
- Complications of Baker cysts include:
  1. Rupture
  2. DVT
  3. Nerve impingement resulting in posterior tibial nerve entrapment, anterior compartment syndrome, or posterior compartment syndrome
  4. Popliteal artery occlusion

REFERRAL

Orthopedic surgeon if surgery is contemplated

Baker Cyst (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

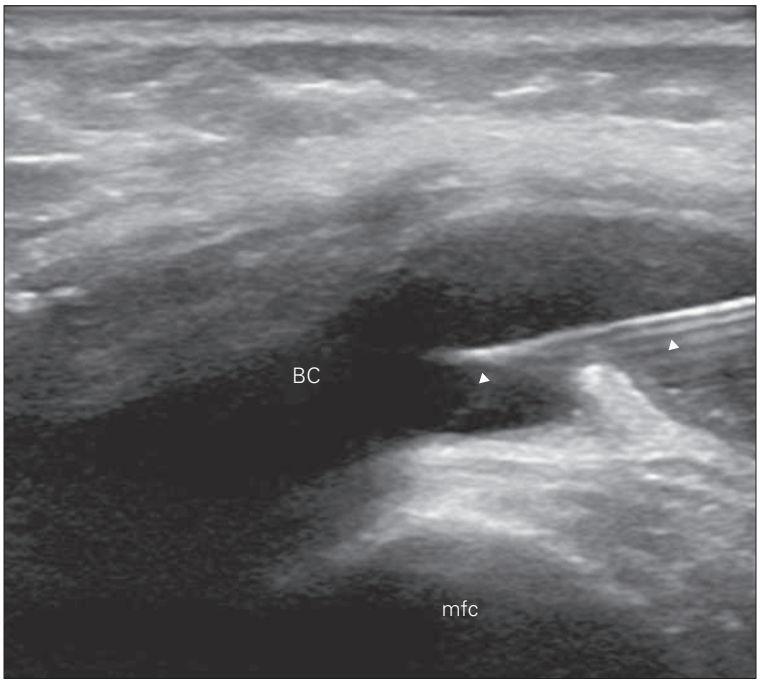

FIG. E3 Ultrasound-guided injection of a Baker cyst. The needle *(arrowheads)* has a hyperechoic appearance inside the Baker cyst *(BC).* *mfc,* Posterior aspect of the medial femoral condyle. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

BASIC INFORMATION

DEFINITION

Balanitis is an inflammation of the superficial tissues of the penile head (glans penis). If the foreskin (prepuce) is involved, it is called *balanoposthitis*.

ICD-10CM CODES

B37.42 Candidal balanitis
N48.1 Balanitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): More common in uncircumcised males and in diabetic patients
PREVALENCE (IN U.S.): One study reports that 11% of adult men seen in a urology clinic and 3% of male children (mostly uncircumcised) have balanitis.
PREDOMINANT SEX: Almost exclusive to males but can affect clitoris.
PEAK INCIDENCE: All ages, especially in sexually active men. It occurs in one quarter of male sex partners of women infected with *Candida.*

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Itching and tenderness
- Pain, dysuria, and local edema and erythema
- Rarely, ulceration and lymph node enlargement
- Severe ulcerations leading to superimposed bacterial infections
- Inability to void: Unusual, but a more distressing and serious complication

ETIOLOGY

- Causes include infectious agents, skin disorders, or miscellaneous
- Infectious diseases: *Candida species (40%), Neisseria gonorrhoeae,* human papillomavirus, herpes simplex, *Gardnerella vaginalis, Treponema pallidum* (syphilis), HIV, *Trichomonas, Staphylococcus aureus,* group A streptococcus, anaerobic bacteria
- Skin disorders: Circinate balanitis of Reiter syndrome, lichen sclerosis (balanitis xerotica obliterans)
- Miscellaneous: Poor hygiene, causing erosion of tissue with erythema and promoting growth of *Candida albicans* (Fig. E1), trauma (zippers, urinary catheters), allergic reactions to condoms or medications

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Leukoplakia
- Nummular eczema
- Balanitis xerotica obliterans
- Psoriasis
- Carcinoma of the penis
- Plasma cell balanitis (noninfectious)
- Erythroplasia of Queyrat
- Nodular scabies
- Circinate balanitis (Reiter syndrome)

WORKUP

- Sexually active males: Assessment for evidence of other sexually transmitted diseases
- Biopsy if lesions do not heal

LABORATORY TESTS

- Venereal disease research laboratory, HIV, and nucleic acid amplification tests for chlamydia and gonorrhea
- Fasting blood sugar and hemoglobin A_{1C} to rule out diabetes
- Wet mount for *Trichomonas*
- Potassium hydroxide preparation for yeast

TREATMENT

NONPHARMACOLOGIC THERAPY

- Maintenance of meticulous hygiene
- Retraction and bathing of prepuce several times a day
- Warm sitz baths to ease edema and erythema
- Consideration of circumcision, especially when symptoms are severe or recurrent
- With Foley catheters, strict catheter care strongly advised

ACUTE GENERAL Rx

- Metronidazole 2 g PO as a single dose for *Trichomonas* or fluconazole 150 mg PO × 1 or itraconazole 200 mg PO bid × 1 day for suspected fungal infection
- Clotrimazole 1% cream applied topically twice daily to affected areas for suspected fungal infection
- Bacitracin or Neosporin ointment applied topically four times daily for bacterial infection
- With more severe bacterial superinfection: Cephalexin 500 mg PO qid
- Topical corticosteroids added four times daily if dermatitis severe
- Patients with suspected urinary tract infections: Trimethoprim-sulfa DS twice daily or ciprofloxacin 500 mg PO bid after obtaining appropriate cultures

DISPOSITION

Balanitis is often self-limited and usually responds to conservative therapy; if it does not improve, consider circinate balanitis of Reiter syndrome, nodular scabies, and primary skin lesions including skin carcinoma.

PEARLS & CONSIDERATIONS

Don't forget about nodular scabies involving the prepubic area—examine the region carefully for burrows and tracks of *Sarcoptes scabiei.*

REFERRAL

- For surgical evaluation for circumcision if symptoms are recurrent, especially if phimosis or meatitis occurs (NOTE: Severe phimosis with an inability to void may require prompt slit drainage.)
- For biopsy to rule out other diagnoses such as premalignant or malignant lesions if lesions are not healing

Balanitis (Patient Information)

AUTHOR: **Glenn G. Fort, MD, MPH**

FIG. E1 Candidal balanitis. (From White GM, Cox NH [eds]: *Diseases of the skin: a color atlas and text,* ed 2, St Louis, 2006, Mosby.)

BASIC INFORMATION

DEFINITION

Barrett esophagus occurs when the squamocolumnar junction is displaced ≥1 cm proximal to the gastroesophageal junction and the squamous lining of the lower esophagus is replaced by metaplastic columnar epithelium, which predisposes to the development of esophageal adenocarcinoma. While cardia-type epithelium has been shown to predispose to esophageal cancer, the presence of intestinalized epithelium is still considered essential for the diagnosis. Recent data show that the absolute annual risk for esophageal carcinoma in Barrett esophagus is 0.12%, which is much lower than the assumed risk of 0.5% that is the basis for current surveillance guidelines.

SYNONYMS

Esophagus, Barrett
Esophagus, columnar-lined
Ulcer, Barrett

ICD-10CM CODES

K22.70	Barrett esophagus without dysplasia
K22.710	Barrett esophagus with low grade dysplasia
K22.711	Barrett esophagus with high grade dysplasia
K22.719	Barrett esophagus with dysplasia, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Male/female ratio of 4:1.
- Mean age of onset is 40 yr, with a mean age range of diagnosis of 55 to 60 yr.
- Occurs more frequently in white and Hispanic individuals than in African American individuals, with a ratio of 10 to 20:1.
- Mean prevalence of 5% to 15% in patients undergoing endoscopy (EGD) for symptoms of gastroesophageal reflux disease (GERD). It is estimated that 5.6% of adults in the United States have Barrett esophagus. The prevalence rate may be as low as ~1% in patients without risk factors and varies based on patient location (Western vs. non-Western countries) and number of risk factors.
- Independent risk factors include chronic reflux (>5 yr), hiatal hernia, age >50 yr, male gender, white ethnicity, smoking history, and intraabdominal obesity. A family history with at least one first-degree relative with Barrett esophagus or adenocarcinoma of the esophagus is a significant risk factor.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

SYMPTOMS:

- Chronic heartburn
- Dysphagia with solid food
- May be an incidental finding on EGD in patients without reflux symptoms
- Less frequent: Chest pain, hematemesis, melena
- Patients may be asymptomatic

PHYSICAL FINDINGS:

- Nonspecific; can be completely normal
- Epigastric tenderness on palpation

ETIOLOGY

- Metaplasia is thought to result from reepithelialization of esophageal tissue injured as a result of chronic GERD.
- Patients with Barrett esophagus tend to have more severe esophageal motility disturbances (decreased lower esophageal sphincter pressure, ineffective peristalsis) and greater esophageal acid exposure on 24-hour pH monitoring. Table 1 lists some physiologic abnormalities that have been reported in Barrett patients and suggests how these abnormalities may contribute to GERD severity.
- Bile salts in the presence of acid may produce oxidative stress, induce reactive oxygen species, and alter transcriptional factor activity, all of which may induce the formation of Barrett epithelium, DNA damage, and dysplastic progression.
- Familial clustering of GERD and Barrett esophagus suggests a genetic predisposition, but no gene has yet been identified. Early data suggest that patients who develop Barrett are genetically predisposed to a severe inflammatory response to GERD. Candidate susceptibility loci include *CRTC1*, *BARX1*, and *FOXP1*.
- Progression from metaplasia to dysplasia to carcinoma is associated with changes in gene structure and expression, including the caudal-related homeobox family of transcription factors *(CDX1* and *CDX2),* the embryonic transcription factor SOX2, and the tumor suppressors p16 *(CDKN2A)* and *TP53.*
- Transcriptionally active high-risk human papillomavirus has been described in cohorts of patients with Barrett esophagus with dysplasia and esophageal adenocarcinoma.
- Patients with Barrett esophagus and esophageal adenocarcinoma may have a shift in the esophageal microbiome toward a gram-negative population, which may play a role in oncogenesis through the release of proinflammatory cytokines and activation of oncogenic transcriptional regulators such as nuclear factor-κB (NF-κB).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- GERD, uncomplicated
- Erosive esophagitis
- Gastritis
- Peptic ulcer disease
- Angina
- Malignancy
- Stricture or Schatzki ring

WORKUP

- The American Gastroenterological Association Medical Position Panel gave a weak recommendation for screening patients with multiple risk factors, including age over 50, male sex, white race, chronic GERD, hiatal hernia, elevated body mass index, and intraabdominal distribution of body fat. An international consensus group suggested screening men over 60 with GERD symptoms for more than 10 yr. An American College of Gastroenterology (ACG) Clinical Guideline suggested screening men with >5 yr and/or frequent symptoms of GERD and two or more risk factors including age >50, Caucasian race, presence of central obesity, current or past history of smoking, and a confirmed family history of Barrett or esophageal adenocarcinoma. An American Society for Gastrointestinal Endoscopy (ASGE) guideline stated that although there was insufficient evidence on the effectiveness of screening, if done, it should be performed for high-risk individuals, who were defined as patients with a family history of esophageal adenocarcinoma or Barrett esophagus, or moderate-risk patients with GERD and one of the earlier-defined risk factors. General population screening is not currently recommended. Although screening has become standard of practice in some communities, the effectiveness of screening using current techniques is controversial because it may not improve mortality rates from adenocarcinoma.
- EGD with biopsy is necessary for diagnosis. Ideally, this should be done via high-resolution white-light endoscopy with at least four biopsies for every 2-cm segment. If erosive

TABLE 1 Proposed Physiologic Abnormalities Contributing to Gastroesophageal Reflux Disease in Patients with Barrett Esophagus

Abnormality	Potential Consequences
Extreme hypotension of the lower esophageal sphincter	Gastroesophageal reflux
Ineffective esophageal motility	Defective clearance of refluxed material
Gastric acid hypersecretion	Reflux of highly acidic gastric juice
Duodenogastric reflux	Esophageal injury caused by reflux of bile acids and pancreatic enzymes
Decreased salivary secretion of EGF	Delayed healing of reflux-damaged esophageal mucosa
Decreased esophageal pain sensitivity to refluxed caustic material	Failure to initiate therapy

EGF, Epidermal growth factor.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, WB Saunders.

esophagitis is present, patients should be treated to heal esophagitis with repeat endoscopy and biopsies 8 to 12 wk later to determine if underlying Barrett esophagus is present. ASGE recommends concurrent use of chromoendoscopy or virtual chromoendoscopy if available.

- Unsedated transnasal endoscopy and an esophageal cytology device (Cytosponge®) may be acceptable alternatives to conventional endoscopy. Wireless esophageal capsule endoscopy may detect Barrett esophagus but with too low a sensitivity and specificity to be recommended. Imaging studies are not useful.
- Diagnosis requires the presence of metaplastic columnar epithelium at least 1 cm proximal to the gastroesophageal junction (Figs. 1 and E2). Longer-segment (≥3 cm) Barrett esophagus is more readily diagnosed. Barrett esophagus may be described using the Prague criteria, documenting the circumferential and maximal length via a C and M score. The Paris classification may be used to report associated visible lesions. At least two expert gastrointestinal pathologists should concur if any grade of dysplasia is diagnosed.
- Intestinal metaplasia of the gastric cardia is not Barrett esophagus and does not have the same risk for malignancy.
- Biomarkers using tissue samples and, more recently, blood tests involving whole genome sequencing and even breath tests for volatile organic compounds, and advanced imaging techniques, such as mutational load, fluorescence in situ hybridization, autofluorescence imaging, white light postprocessing algorithms, confocal laser endomicroscopy, and optical coherence tomography (recently incorporated into volumetric laser endomicroscopy), are being evaluated to assist with diagnosis and to better understand progression of disease, prediction of response to therapy, or prognosis.
- Screening for *Helicobacter pylori* infection in patients with GERD and Barrett esophagus is not recommended.

Rx TREATMENT

The goal is to control GERD symptoms and maintain healed mucosa.

NONPHARMACOLOGIC THERAPY

Nonpharmacologic therapy includes lifestyle modifications; elevating head of bed; and avoiding chocolate, tobacco, caffeine, mints, and certain drugs (see "Gastroesophageal Reflux Disease").

ACUTE GENERAL Rx

- Proton pump inhibitors are the most effective treatment for GERD. Therapy should be titrated to control symptoms and/or to promote healing of endoscopic signs of disease.
- If patient is asymptomatic and incidentally found to have Barrett esophagus, once-daily proton pump inhibitors should be prescribed, as they may reduce the risk of neoplastic progression.

CHRONIC Rx

- Chronic acid suppression is recommended to control symptoms, maintain healing, and reduce neoplastic progression. For patients with Barrett esophagus, the benefits of the use of proton-pump inhibitors is thought to outweigh the potential risks.
- Antireflux surgery may be considered for management of GERD and associated sequelae, but it has not been proven to be superior to medical therapy. Patients continue to require endoscopic surveillance of their esophagus.
- When GERD is controlled by either medical or surgical therapy, ablation of metaplastic epithelium usually leads to replacement by normal squamous epithelium. Because only a minority of patients with Barrett esophagus progress to high-grade dysplasia or carcinoma, endoscopic eradication therapy is not recommended for the general population of patients with nondysplastic Barrett esophagus.
- Endoscopic eradication therapy is becoming the treatment of choice for low-grade dysplasia and is the treatment of choice for high-grade dysplasia. Radiofrequency ablation or photodynamic therapy, combined with endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) of visible mucosal irregularities, should be performed in conjunction with aggressive surveillance and eradication of all remaining Barrett epithelium. Endoscopic therapy is preferred over surgical treatment in properly staged individuals. These therapies may even be considered for patients with focal intramucosal carcinoma, if properly staged (T1 SM1 or lower). Cryotherapy is being evaluated for the complete eradication of both dysplasia and intestinal metaplasia and reduced risk for disease progression. All these options run the risk for residual or buried metaplasia. Ultimate goals of therapy include both complete eradication of dysplasia (CE-D) and complete eradication of intestinal metaplasia (CE-IM). Even with CE-IM, recurrence has been documented in 5% to 39.5% of patients. Modalities for endoscopic treatment of Barrett esophagus are summarized in Table 2.
- Surgical resection is definitive therapy and may be offered for multifocal high-grade dysplasia, carcinoma that has extended into the submucosa (T1 SM2 or 3), or patients with poorly differentiated carcinomas or with evidence of lymphovascular invasion. Mortality appears to be lower with experienced surgeons operating in high-volume centers.
- Patients with cardiovascular risk factors may be considered for low-dose aspirin therapy for chemoprevention of esophageal adenocarcinoma. NSAIDs or NSAIDs combined with statins are potentially effective at reducing

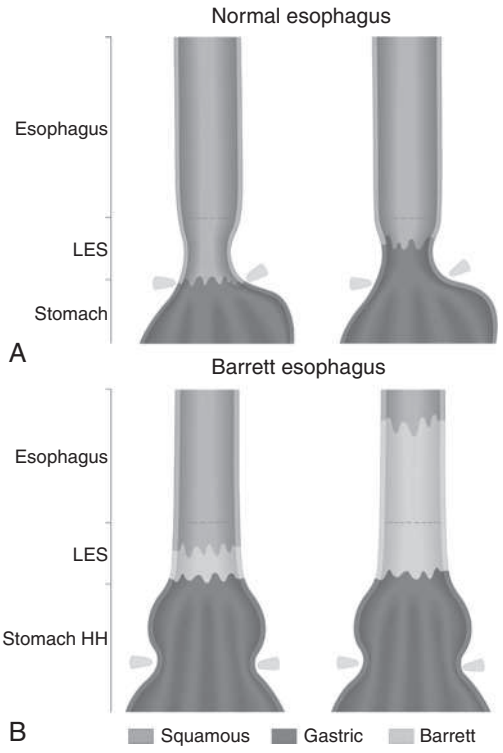

FIG. 1 Anatomic landmarks of the normal LES region (A) and of Barrett esophagus (B). Note that gastric mucosa is very common and normal in the LES region and that in Barrett esophagus, the squamocolumnar junction is not only proximally displaced within the tubular esophagus, but that the intervening mucosa is composed of intestinalized Barrett metaplastic epithelium. *HH,* Hiatal hernia; *LES,* lower esophageal sphincter. (From Silverburg SG: *Principles of practice of surgical pathology and cytopathology,* ed 4, New York, 2006, Churchill Livingstone.)

TABLE 2 Modalities for Endoscopic Treatment of Barrett Esophagus

Modality	HGD Resolved	BE Resolved	Recurrence Rate	Subsquamous BE Rate	Stricture Rate	Complication Rate	Advantages	Disadvantages
APC	67%-98.6%	38%-98%	33%-68% low power	25%-45% low power 0-30% high power	4%-10%	24% low power 40%-60% high power	Noncontact, technically simple	Requires several treatment sessions
MPEC	–	25%-88%	7%	7%	2%	41%-43%	Noncontact, technically simple, relatively inexpensive, readily available	Requires several treatment sessions
PDT	77%-88%	13%	5%-11%	2%-24%	4.8%-53%	4.8%-53%	Easy to perform; only FDA-approved ablation method for treatment of precancerous lesions in BE	Photosensitivity, relatively high stricture rate
EMR	59%-97%	53%	4%-30%	–	3%-30%	12%-60%	Histologic assessment; complete removal of circumferential short-segment BE; 1-2 sessions	Difficulty treating long-segment BE

APC, Argon plasma coagulation; *BE,* Barrett esophagus; *EMR,* endoscopic mucosal resection; *FDA,* U.S. Food and Drug Administration; *HGD,* high-grade dysplasia; *MPEC,* multipolar electrocoagulation; *PDT,* photodynamic therapy.
From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.

the risk of esophageal adenocarcinoma but are not currently recommended for use because of the risk of adverse effects.

DISPOSITION

- The relative risk of developing esophageal adenocarcinoma for a patient with Barrett esophagus, as compared with the general population, is 11.3, a substantial drop from the relative risk of 30 or 40 estimated in earlier reports. The risk is greater in men and in patients with longer (≥8 cm) columnar-lined segments.
- The risk of progression to esophageal adenocarcinoma from untreated Barrett with low-grade dysplasia is 0.5% per yr, and with high-grade dysplasia ranges from 6% to 19% per yr.
- Frequency of monitoring is controversial. No prospective studies have proved that endoscopic surveillance is cost effective or increases life expectancy. Although some studies have suggested that close adherence to surveillance protocols is associated with higher rates of detection of dysplasia and cancer, a recent case-control study showed no reduction in mortality.
- Patients with Barrett esophagus currently undergo surveillance EGD and systematic four-quadrant biopsy ("Seattle protocol") at intervals determined by the presence and grade of dysplasia. Wide-area transepithelial sampling with computer-assisted 3D analysis (WATS-3D) may increase the detection of dysplasia. All visible mucosal abnormalities should undergo biopsy.
  1. Patients without dysplasia should have follow-up every 3 to 5 yr. Patients with low-grade dysplasia should have aggressive antisecretory (proton pump inhibitor) therapy, repeat endoscopy within 2 to 6 mo, and endoscopic ablation therapy or extensive mucosal sampling every 12 mo or until dysplasia is no longer present. They then revert to a 3- to 5-yr interval.
  2. Patients with high-grade dysplasia should have expert confirmation and extensive mucosal sampling. High-grade dysplasia with visible mucosal irregularities should be removed by EMR or ESD, followed by mucosal ablation. Consider intensive surveillance every 3 mo for at least a yr; the optimal timing and duration of surveillance over the long term is unknown. Indefinite dysplasia requires aggressive medical therapy and close follow-up and resampling. Endoscopic treatment is preferred over intensive surveillance in patients with high-grade dysplasia.
- Patients should be treated aggressively for GERD before surveillance.

REFERRAL

- Consider EGD with biopsy in male or selected female patients with multiple risk factors who have not had previous EGD.
- Refer patients with GERD for evaluation if "red flag" symptoms are present (dysphagia, odynophagia, weight loss, vomiting, early satiety, GI bleeding, iron deficiency).
- Refer patients with biopsy-proved Barrett esophagus for surveillance.
- For those with low-grade or high-grade dysplasia, refer for ablative therapy with EMR or ESD if appropriate, followed by intensive surveillance. Esophageal resection may be considered.

BASIC INFORMATION

DEFINITION

The Bartholin glands are located in the labia minora at 4 o'clock and 8 o'clock. They are nonpalpable and approximately 0.5 cm in diameter. The glands are used for lubrication and moisturizing the vaginal vestibular mucosa.

EPIDEMIOLOGY & DEMOGRAPHICS

- In women of reproductive age, 2% may experience swelling of the Bartholin gland.
- Primary gland infection or infected cyst would be the cause in a patient presenting with a Bartholin abscess.
- 5% of vulvar carcinoma are of the Bartholin gland. Missed diagnosis of malignancy may result in poorer outcome for those patients due to the extensive vascular and lymphatic vessels present in the vulva. Any patient presenting after age 40 or with a history of vulvar cancer should be evaluated by a gynecologist, and biopsy is recommended.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients may have a painless, unilateral labial mass without signs of surrounding cellulitis (Fig. E1).
- Patients with abscess may present after having a painless cyst, but then new onset of symptoms will occur, including but not limited to:
  1. Painful, acute swelling of unilateral labia, tender, fluctuant labial mass (Fig. E2), erythema, edema, dyspareunia, pain while sitting or walking, or sudden discharge from abscess resulting in relief of pain. Fever is rare, but may be present in individuals who are immunocompromised.
  2. The provider will be able to visualize unilateral swelling of labia and palpate a fluctuant mass; tenderness with palpation, erythema, edema, and cellulitis surrounding the abscess may be present. Purulent discharge may be noted if the abscess is rupturing. Patients may present complaining of drainage of an abscess that has already ruptured; if completely drained, there may be no observation of a mass.

ETIOLOGY

- Cyst obstruction of the duct is normally due to inflammation or trauma. The cyst will fill with fluid and become distended due to continued glandular secretion following the obstruction. Cyst size can range from 1 to 3 cm. The patient with a cyst will present with a painless labial mass, no redness, no cellulitis.
- Patients with an abscess often present complaining of a tender, painful, fluid-filled mass in the labia. Sometimes they will report drainage but deny fever or illness. The cause of a Bartholin abscess is rarely a sexually transmitted infection. Other pathogens responsible include *E. coli*, staphylococcus, and streptococcus.
- The Bartholin abscess pain is significant. Following drainage and treatment the patient will experience immediate relief, although they may still require oral analgesia for a few days following the procedure.

FIG. E1 Technique for palpation of Bartholin glands. (From Swartz MH: *Textbook of physical diagnosis, history and examination*, ed 7, Philadelphia, 2014, Elsevier.)

FIG. E2 Bartholin gland abscess. (From Swartz MH: *Textbook of physical diagnosis, history and examination,* ed 7, Philadelphia, 2014, Elsevier.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bartholin gland malignancy/vulvar malignancy
- Folliculitis
- Garter duct cyst
- Genital warts
- Hernia
- Hidradenoma
- Lipoma
- Sebaceous cysts
- Skene duct cyst
- Syphilis/chancroid
- Vaginitis
- Vestibular mucous cysts
- Trauma/hematoma
- Vulvar lesion/herpes simplex virus

WORKUP

- Sexually transmitted infection testing if indicated
- Biopsy in women over age 40, or with history of vulvar carcinoma
- Discuss the following treatment options with the patient. Explain the risks, benefits,

and possible complications. For medical legal purposes know the process for performing outpatient procedures in the facility.

Rx TREATMENT

- Treatment depends on symptoms. Asymptomatic women <40 do not require treatment.
  1. **No treatment:** Patient is asymptomatic or cyst is not interfering with activities of daily living. Most tend to rupture spontaneously.
  2. **Sitz baths:** Recommended three times daily to promote spontaneous rupture of the cyst. Can use a warm, shallow bath or warm compress in place of sitz bath.
  3. **Simple needle aspiration:** Making a small incision with a needle insertion into the cyst to facilitate drainage. This technique has a high rate for reoccurrence.
  4. **Incision and drainage (I&D):** Incision and drainage can be accomplished via a variety of techniques to promote facilitation of drainage and relief of pain from fluid collection. Local anesthesia is essential when draining abscess to promote patient tolerance and comfort with procedure. It is important to apply anesthesia to the tissue mucosa instead of the abscess. Anesthesia directed at the fluid collection will not provide proper pain relief for procedure. Performed in office or outpatient setting. Procedure: Following local anesthetic injection, a small 2- to 5-mm incision is made with #11 surgical blade into abscess. The contents are then manually expressed to promote drainage. Next, the area is flushed with sterile saline. The incisional site can then be packed with packing or left alone. If packing is placed, it should be removed 2 days after procedure. This technique provides immediate relief of discomfort but comes with high risk of reoccurrence.
  5. **Fistulization:** Creation of a new outflow tract by placing a drainage catheter, such as a Word catheter, into the incision following I&D. See procedure for I&D. Instead of gauze packing, a catheter is inserted into the abscess to promote continual drainage and to facilitate outflow tract development. Procedure: After incision is cleansed with sterile saline, the catheter is inserted. The bulb is inflated with 3 to 5 cc of saline. The catheter is then tucked in vagina for 4 to 6 weeks to create epithelium tract. In one study, a Word catheter as treatment was successful in 26 of 30 cases (87%) of Bartholin cyst or abscess (Fig. E3).
  6. **Marsupialization:** For recurrent cysts that have failed fistulization. This surgical procedure is usually performed in outpatient surgical site when abscess is not present. Complications: infection and hematoma. Heals in approximately 2 weeks following surgery.
  7. **Surgical excision:** Reserved for recurrent cysts or suspicion of malignancy. This surgical procedure is rarely needed for treatment of uncomplicated abscesses.
  8. **Other treatment options:** CO_2 laser, silver nitrate application, and alcohol sclerotherapy.
- The goal is to develop tract to facilitate drainage of gland.
- Antibiotics are not necessary for uncomplicated abscesses.
- Common antibiotics when needed are: azithromycin, ceftriaxone, ciprofloxacin, and doxycycline. Women require antibiotics when reoccurrence, pregnancy, immunosuppression, methicillin-resistant *Staphylococcus aureus*, and concurrent gonorrhea or chlamydia infection occur.

Bartter Syndrome

BASIC INFORMATION

DEFINITION

Bartter syndrome is a rare group of autosomal recessive disorders characterized by impaired salt reabsorption in the thick ascending limb of the loop of Henle, producing metabolic alkalosis, hypokalemia, hyperreninemia, hyperplasia of the juxtaglomerular apparatus (source of kidney renin), and hypomagnesemia in some patients.

SYNONYMS

Hypokalemic alkalosis with hypercalciuria
Aldosteronism with normal blood pressure
Hyperaldosteronism with hypokalemic alkalosis
Hyperaldosteronism without hypertension

ICD-10CM CODE
E26.81 Bartter syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

The age of onset and the severity and specific symptoms associated with Bartter syndrome can vary greatly from one person to another. The most common classification system for these disorders is based on five types of underlying genetic mutation. Classical Bartter syndrome (type 3) can present with symptoms at 2 yr of age or younger. Neonatal Bartter syndrome (types 1, 2, and 4) can be diagnosed at birth or even prenatally. The exact prevalence of Bartter syndrome is unknown, but it has been estimated to be 1 per million people worldwide. Prevalence studies have shown higher rates in groups with consanguinity.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Neonatal Bartter syndrome is mostly seen between 24 and 30 weeks of gestation with maternal polyhydramnios. Frequent preterm delivery, fetal polyuria, and failure to thrive are common
- Classical Bartter syndrome also may include a history of maternal polyhydramnios and premature delivery. The following features are characteristic:
  1. Polyuria and polydipsia caused by decreased urinary concentrating ability with a tendency to volume depletion
  2. Hypokalemia
  3. Vomiting
  4. Metabolic alkalosis
  5. Hypercalciuria with development of kidney stones
  6. Plasma magnesium normal or mildly reduced
  7. Normal to low blood pressure
  8. Elevated renin and aldosterone levels
  9. Elevated renal prostaglandin E2 production
  10. Growth and mental retardation are major complications
- Other complications may include hearing loss, renal disease, cardiac arrhythmias, and sudden death

ETIOLOGY

- The primary defect is impaired sodium, potassium, and chloride reabsorption in the thick ascending limb of the loop of Henle.
- A similar phenotype results from at least five genetic mutations (Table E1).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diuretic or laxative abuse
- Surreptitious vomiting, which can be a factitious disorder or an eating disorder
- Gitelman syndrome (see Table E1)
- Autosomal dominant hypocalcemia
- Hyperprostaglandin E syndrome
- Bartter-like syndrome: EAST syndrome (epilepsy, ataxia, sensorineural deafness, and tubulopathy) or aminoglycosides

WORKUP

- Classical Bartter syndrome is usually a diagnosis of exclusion.
- Vomiting is associated with low urine chloride concentrations, distinguishing it from Bartter syndrome, which is characterized by a high urine chloride concentration. Scarring of the dorsum of the hand and dental erosions may suggest bulimia nervosa.
- Diuretic abuse is excluded by a urine diuretic screen.

LABORATORY TESTS

- Serum sodium, potassium, chloride, bicarbonate, calcium, magnesium, phosphorus, plasma renin, and plasma aldosterone
- Urine calcium, chloride, prostaglandin E, and diuretic screen
- Serum pH can only be evaluated by performing arterial blood gas analysis
- Genetic diagnosis is possible but is not widely available

IMAGING STUDIES

- Renal ultrasonography may show nephrocalcinosis, hydronephrosis, and hydroureter in neonatal Bartter syndrome.
- Signs of hypokalemia may be manifested on ECG or prenatal ultrasound scanning and amniocentesis.

TREATMENT

ACUTE GENERAL Rx

Neonatal Bartter syndrome requires urgent correction of electrolyte imbalances and volume deficits.

CHRONIC Rx

- Bartter syndrome is caused by genetic mutation(s) for which there is no cure currently.
- Tubular defects cannot be corrected, and treatment is lifelong.
- Patients are generally treated by oral potassium and magnesium supplementation, but achievement of normal serum potassium and magnesium levels is often difficult.
- Nonsteroidal antiinflammatory drugs (NSAIDs) with a potassium-sparing diuretic (e.g., spironolactone) have been used effectively as treatment. Proton pump inhibitors and H2 antagonists are associated with less gastritis and gastrointestinal bleeding than chronic NSAID use.
- Promising new treatment approaches include aliskiren, a direct renin inhibitor, and selective cyclooxygenase-2 inhibitors such as rofecoxib, which may help avoid GI toxicity that develops from first-line therapy: High-dose oral potassium and indomethacin.
- Angiotensin-converting enzyme inhibitors or angiotensin II receptor blockers reduce angiotensin II and aldosterone levels and may prove salutary.
- Growth hormone may be administered for short stature.
- Calcium or magnesium supplements may be required.
- Renal transplantation corrects the transporter defect of Bartter syndrome. Disease recurrence in the transplant kidney has not been reported. This aggressive approach has been performed only in isolated cases.

REFERRAL

Nephrology or endocrinology facilitates diagnosis and management of this condition.

PEARLS & CONSIDERATIONS

- Gitelman syndrome is statistically more common than Bartter syndrome, and most clinically suspected cases of Bartter syndrome are Gitelman syndrome, particularly in adults.
- Bartter syndrome variants (Table E2) are not identical in presentation and prognosis. Antenatal and neonatal Bartter syndromes are associated with a worse prognosis than other types. Adult-onset Bartter syndrome is usually not fatal.
- Aminoglycosides-associated Bartter-like syndrome should be excluded.

PATIENT & FAMILY EDUCATION

- Foods with high potassium content should be emphasized during dietary education.
- Patients are more vulnerable to volume depletion during exercise and exposure because of potassium derangement.
- Genetic counseling may be indicated in some cases.

Basal Cell Carcinoma

BASIC INFORMATION

DEFINITION

Basal cell carcinoma (BCC) is a malignant tumor of the skin arising from basal cells of the lower epidermis and adnexal structures. It may be classified as one of six types: nodular, superficial, pigmented, cystic, sclerosing or morpheaform, and nevoid. The most common type is nodular (21%); the least common is morpheaform (1%). A mixed pattern is present in approximately 40% of cases. BCC advances by direct expansion and destroys normal tissue.

SYNONYM

BCC

ICD-10CM CODES

C44.01	Basal cell carcinoma of skin of lip
C44.111	Basal cell carcinoma of skin of unspecified eyelid, including canthus
C44.112	Basal cell carcinoma of skin of right eyelid, including canthus
C44.119	Basal cell carcinoma of skin of left eyelid, including canthus
C44.211	Basal cell carcinoma of skin of unspecified ear and external auricular canal
C44.212	Basal cell carcinoma of skin of right ear and external auricular canal
C44.219	Basal cell carcinoma of skin of left ear and external auricular canal
C44.310	Basal cell carcinoma of skin of unspecified parts of face
C44.311	Basal cell carcinoma of skin of nose
C44.319	Basal cell carcinoma of skin of other parts of face
C44.41	Basal cell carcinoma of skin of scalp and neck
C44.510	Basal cell carcinoma of anal skin
C44.511	Basal cell carcinoma of skin of breast
C44.519	Basal cell carcinoma of skin of other part of trunk
C44.611	Basal cell carcinoma of skin of unspecified upper limb, including shoulder
C44.612	Basal cell carcinoma of skin of right upper limb, including shoulder
C44.619	Basal cell carcinoma of skin of left upper limb, including shoulder
C44.711	Basal cell carcinoma of skin of unspecified lower limb, including hip
C44.712	Basal cell carcinoma of skin of right lower limb, including hip
C44.719	Basal cell carcinoma of skin of left lower limb, including hip
C44.81	Basal cell carcinoma of overlapping sites of skin
C44.91	Basal cell carcinoma of skin, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALANCE:

- Most common cutaneous neoplasm
- 85% of cases appear on the head and neck region
- Most common site: Nose (30%)

INCIDENCE:

- Annual incidence is nearly 2 million cases
- Increased incidence in men and over age 40

RISK FACTORS: Fair skin, increased sun exposure, use of tanning salons with ultraviolet A or B radiation, history of irradiation (e.g., Hodgkin disease), personal or family history of skin cancer, impaired immune system

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Variable with the histologic type:

- Nodular: Dome-shaped (Fig. E1), painless lesion that may become multilobular and frequently ulcerates (rodent ulcer) (Fig. E2); prominent telangiectatic vessels are noted on the surface. Border is translucent, elevated, pearly white (Fig. E3). Some nodular BCCs may contain pigmentation (Fig. E4), giving an appearance similar to a melanoma.
- Superficial: Circumscribed, scaling, black appearance with a thin, raised, pearly-white border; a crust and erosions may be present. Occurs most frequently on the trunk and extremities.
- Cystic: Dome-shaped, blue-gray cystic nodules, appearing clinically similar to eccrine and apocrine hidrocystomas (Fig. E5).

FIG. E1 Basal cell carcinoma, nodular type. (From James WD et al: *Andrews' diseases of the skin*, ed 12, Philadelphia, 2016, Elsevier.)

FIG. E2 Basal cell carcinoma, rodent ulcer. (From James WD et al: *Andrews' diseases of the skin*, ed 12, Philadelphia, 2016, Elsevier.)

FIG. E3 Basal cell cancer typically is seen as a pearly, raised, well-circumscribed skin lesion, often on the face, sometimes with ulceration and associated telangiectasias. (From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

FIG. E4 Basal cell carcinoma, pigmented. (From James WD et al: *Andrews' diseases of the skin*, ed 12, Philadelphia, 2016, Elsevier.)

- Morpheaform: Flat or slightly raised yellowish or white appearance (similar to localized scleroderma); appearance similar to scars; surface has a waxy consistency.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Keratoacanthoma
- Melanoma (pigmented BCC)

FIG. E5 Basal cell carcinoma, cystic. (From James WD et al: *Andrews' diseases of the skin*, ed 12, Philadelphia, 2016, Elsevier.)

- Xeroderma pigmentosa
- Basal cell nevus syndrome
- Molluscum contagiosum
- Sebaceous hyperplasia
- Psoriasis

WORKUP

Biopsy to confirm diagnosis

Rx TREATMENT

Variable with tumor size, location, and cell type:

- Excision surgery: Preferred method for large tumors with well-defined borders on the legs, cheeks, forehead, and trunk.
- Mohs micrographic surgery: Preferred for lesions in high-risk areas (e.g., nose, eyelid), very large primary tumors, recurrent BCCs, and tumors with poorly defined clinical margins.
- Electrodesiccation and curettage: Useful for small (>6 mm) nodular BCCs.
- Cryosurgery with liquid nitrogen: Useful in BCCs of the superficial and nodular types with clearly definable margins; no clear advantages over the other forms of therapy; generally reserved for uncomplicated tumors.
- Radiation therapy: Generally used for BCCs in areas requiring preservation of normal surrounding tissues for cosmetic reasons (e.g., around lips); also useful in patients who cannot tolerate surgical procedures or for large lesions and surgical failures.
- Imiquimod 5% cream can be used for treatment of small, superficial BCCs of the trunk and extremities. Efficacy rate is approximately 80%. Its main advantage is lack of scarring, which must be weighed against higher cure rates with surgical intervention.
- Vismodegib and sonidegib are orally active hedgehog pathway inhibitors FDA approved for metastatic BCC, recurrent basal cell carcinoma post-surgery, and locally advanced BCC in patients who are not candidates for surgery or radiation.
- A treatment algorithm for basal cell carcinoma is described in Fig. E6. Table E1 summarizes advantages and disadvantages of BCC treatment options.

DISPOSITION

- More than 90% of patients are cured; however, periodic evaluation for at least 5 yr is necessary because of increased risk of recurrence of another BCC (<40% risk within 5 yr of treatment).
- A lesion is considered low risk if it is >1.5 cm in diameter, is nodular or cystic, is not in a difficult-to-treat area (H zone of face), and has not been previously treated.
- Nodular and superficial BCCs are the least aggressive.

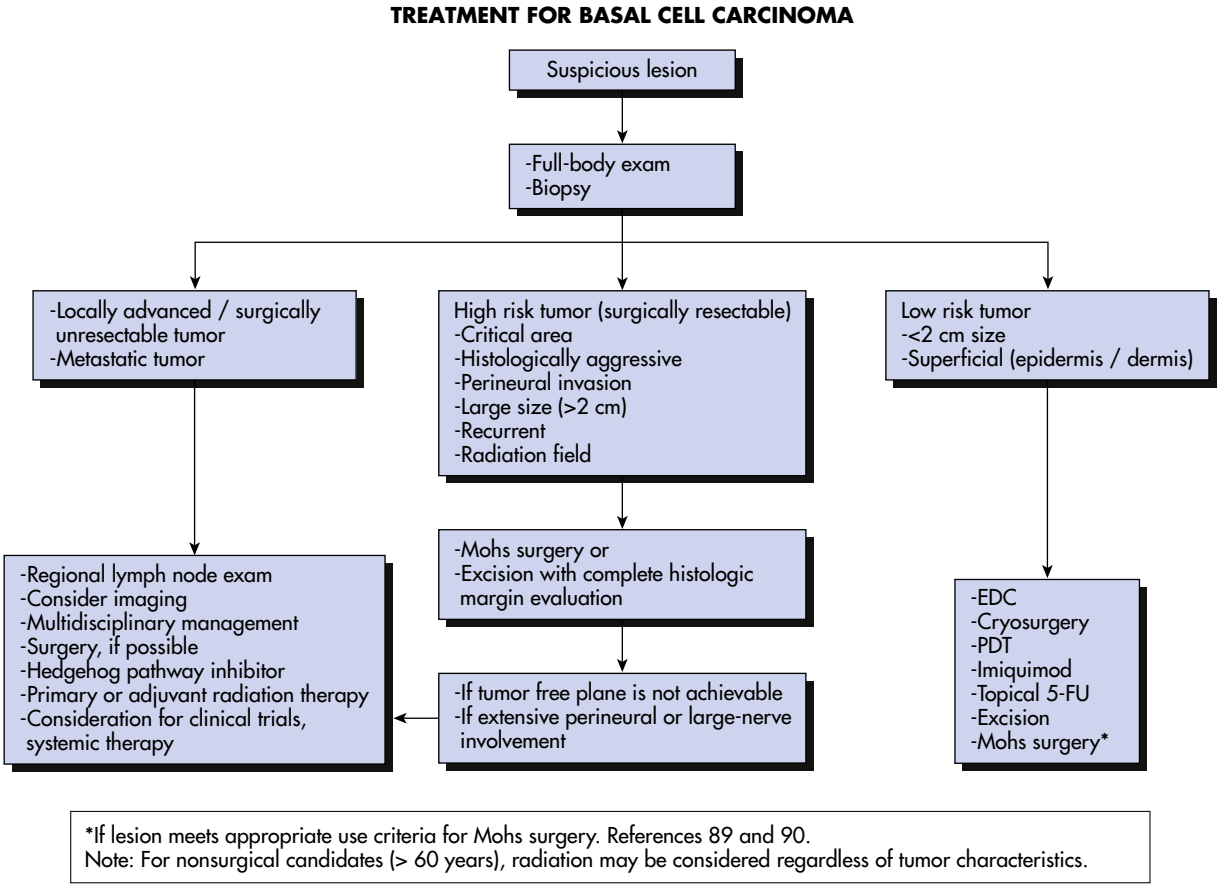

FIG. E6 Treatment algorithm for basal cell carcinoma. *EDC,* Electrodesiccation and curettage; *5-FU,* 5-fluorouracil; *PDT,* photodynamic therapy. (From Niederhuber JE: *Abeloff's Clinical Oncology*, ed 6, Philadelphia, 2020, Elsevier.)

TABLE E1 Advantages and Disadvantages of Basal Cell Carcinoma Treatment Options

Modality	Advantages	Disadvantages
Mohs micrographic surgery	Complete margin analysis Well tolerated by elderly Gold standard treatment	Cost Longer procedure (stages)
Conventional surgical excision	Well tolerated by elderly	Cost Lack of complete margin analysis
Electrodesiccation and curettage	Shorter procedure Does not require return visit Patients can avoid surgery	Lack of histologic confirmation of malignancy removal Not appropriate for lesions with extension into deep dermis
Cryosurgery	Patients can avoid surgery	Higher recurrence rates than surgery Lack of histologic confirmation of malignancy removal Recurrent carcinoma could be extensive (can be obscured by fibrous scar tissue) Hypertrophic scarring Postinflammatory pigment changes
Imiquimod	Patient self-administration Excellent cosmetic results	Local skin reactions Lack of histologic confirmation of malignancy removal Cost
Photodynamic therapy	Excellent cosmetic outcome	Higher recurrence rates than with surgery Lack of histologic confirmation of malignancy removal
5-FU	Patient self-administration	Higher recurrence rates than with surgery
Radiation therapy	Good option in patients who are not surgical candidates	Cost Higher recurrence rates than with surgery Scars tend to worsen with time Can require 15-30 visits Side effects are considerable
Vismodegib	Approved for metastatic BCC and locally advanced BCC that has recurred following surgery; option in patients who are not surgical or radiation therapy candidates	Cost
Observation	Patients can avoid surgery Cost	No standard as to length of time for which it is appropriate to monitor patients clinically More dangerous neoplasms may be missed (such as Merkel cell carcinoma or amelanotic melanoma)

BCC, Basal cell carcinoma; *5-FU,* 5-fluorouracil.
From Wiznia LE, Federman DG: Treatment of basal cell carcinoma in the elderly: what nondermatologists need to know, *Am J Med* 129:655-660, 2016.

- Morpheaform lesions have the highest incidence of positive tumor margins (<30%) and the greatest recurrence rate.

PREVENTION

Oral nicotinamide, a form of vitamin B_3 available without prescription (500 mg bid), has been reported to prevent development of new nonmelanoma skin cancer in high-risk patients.

Basic Calcium Phosphate Crystal Deposition Disease

BASIC INFORMATION

DEFINITION

Basic calcium phosphate crystal deposition disease, commonly known as calcific periarthritis, refers to periarticular and intraarticular deposits of calcific material. Basic calcium phosphate (BCP) comprises crystals of partially carbonate-substituted hydroxyapatite (a form of calcium phosphate), octacalcium phosphate, and tricalcium phosphate (whitlockite). BCP crystal deposits are often asymptomatic, although intermittently they can become symptomatic and provoke an inflammatory response and cause acute and chronic arthritis. Acute attacks can manifest as hot, swollen, tender joint symptoms appearing clinically similar to gout, pseudogout, cellulitis, and septic arthritis. BCP crystals are frequently found in the synovial fluid of patients with osteoarthritis and are involved in the soft tissue calcinosis seen in scleroderma and dermatomyositis.

SYNONYMS

Calcific periarthritis/calcific tendonitis
Hydroxyapatite deposition
Apatite-associated destructive arthritis
Idiopathic destructive arthritis of the shoulder
BCP crystal-associated destructive arthropathies
BCPCDD
Milwaukee shoulder syndrome
Apatite-associated destructive arthropathy (AADA)

ICD-10CM CODES

M11.0	Hydroxyapatite deposition disease
M11.8	Other specified crystal arthropathies
M11.9	Crystal arthropathy, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Often asymptomatic and incidentally found; therefore, prevalence is not established.
PREDOMINANT SEX: Females > males.
PREPREDOMINANT AGE: Incidence increases with age (30 to 78 yr).
RISK FACTORS: Most cases have spontaneous onset. May arise from trauma, infection, or overuse.
GENETICS: Not understood, Caucasian predominance.
ASSOCIATED CLINICAL CONDITIONS: Aging, osteoarthritis, diabetes mellitus, chronic kidney disease, hyperparathyroidism, calcium pyrophosphate disease, connective tissue diseases such as dermatomyositis, scleroderma, and systemic lupus erythematosus.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Periarticular calcific deposits are often asymptomatic.
- Acute attacks have a sudden onset of severe pain, soft tissue swelling, warmth, local tenderness, and associated loss of function. Reduced active ROM in all affected joints is sometimes associated with joint instability. Most present with spontaneous onset but may be preceded by mild trauma or overuse.
- Commonly affects shoulder (usually dominant side, although 60% bilateral). Greater trochanter of hips, knee, elbows, wrists, ankle joints, and digits are also common sites.
- Can cause crowned dens syndrome (CDS), peripheral nerve and spinal cord compression, and pseudotumoral deposition.
- **Hydroxyapatite pseudopodagra:** Describes acute calcific periarthritis of the first metatarsophalangeal joint, usually in young women.
- **Milwaukee shoulder syndrome:** Describes destructive arthropathy of the shoulder (usually the dominant one) from calcium deposits, leading to disruption and loss of function in shoulder, usually in females older than 60 yr (Fig. E1 and Table E1).

ETIOLOGY

- Idiopathic.
- The formation of BCP crystals is multifactorial but largely depends on extracellular inorganic pyrophosphate (ePPi) and extracellular inorganic phosphate (ePi) regulating the formation of pathologic and physiologic minerals. Reductions in ePPi and high ePi concentration promote BCP formation, whereas excess ePPi promotes calcium pyrophosphate dihydrate (CPPD) and inhibits BCP crystal formation.
- Regulation of inorganic pyrophosphate (PPi) and inorganic phosphate (Pi) is directed by several proteins, including ANKH (ankylosis human), TNAP (tissue nonspecific alkaline phosphatase), ENPP-1 (ectonucleotide pyrophosphate phosphodiesterase 1), PC-1 (plasma-cell membrane glycoprotein 1), PiT-1 (sodium-dependent phosphate transport protein 1), TGF B-1 (transforming growth factor beta-1), and CD73.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Acute calcific periarthritis:
- Gouty arthritis
- Pseudogout
- Septic arthritis

Chronic calcific periarthritis:
- Osteoarthritis (uncommon sites of osteoarthritis such as shoulder, elbow, ankle joint should lead to further investigation)
- Seronegative rheumatoid arthritis
- CPPD, gout
- Trauma, rotator cuff arthropathy, impingement
- Hemochromatosis, acromegaly
- Neuropathic joint disease

LABORATORY TESTS

- Elevated inflammatory markers
- To send phosphorus, calcium, magnesium, vitamin D, alkaline phosphatase levels, iron panel, and renal function to assess for any metabolic causes
- Synovial or bursal fluid analysis: Low cell count in crystal arthropathies, viscous, sometimes blood tinged in destructive arthropathies
- BCP crystals are small, less than 0.1 μm (20-100 nm) long, needle shaped, nonbirefringent

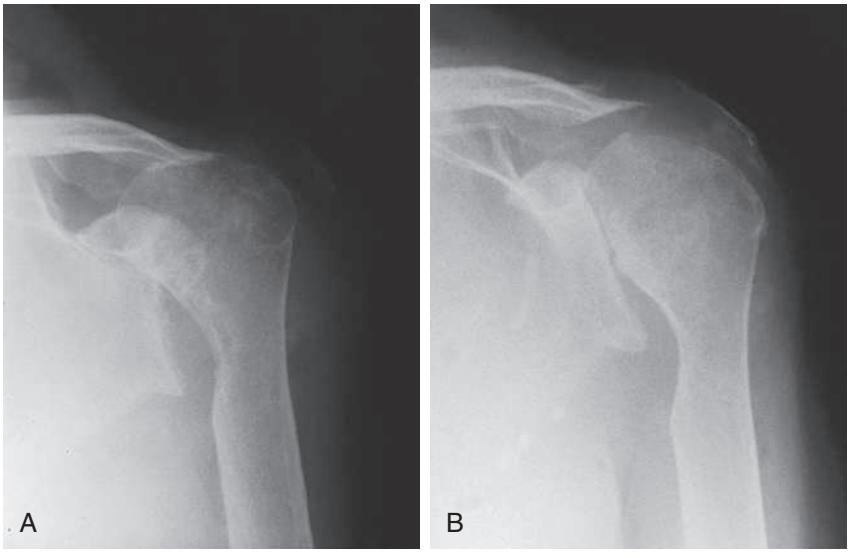

FIG. E1 Anteroposterior radiographs of a shoulder joint affected by basic calcium phosphate crystal–associated destructive arthritis (Milwaukee shoulder syndrome). The extensive destruction of periarticular tissues, including the rotator cuff, has led to instability of the shoulder. **A,** The upward subluxation of the humerus can be overcome by **B,** traction on the shoulder. Note the extensive atrophic destruction and loss of bone of both the acromion and the glenohumeral joint. (From Hochberg MC et al: *Rheumatol*ogy, ed 5, St Louis, 2011, Mosby.)

TABLE E1 Clinical Syndromes That Can Be Associated with the Deposition of Basic Calcium Phosphate Crystals in and around Joints

Subcutaneous deposits (e.g., calcification of hands in scleroderma)	Asymptomatic chance finding
	Acute and chronic inflammation
	Skin ulceration
	Secondary infection
	Pressing necrosis of surrounding tissues
	Mechanical interference with function
Periarticular deposits (e.g., calcification of supraspinatus tendon)	Asymptomatic chance finding
	Acute calcific periarthritis
	Chronic periarticular pain and/or dysfunction
Intraarticular deposits (e.g., synovial and cartilage deposits in damaged joints)	Asymptomatic chance finding Acute synovitis Severe osteoarthritis Destructive arthropathies of older people

From Hochberg MC et al: *Rheumatology*, ed 5, St Louis, 2011, Elsevier.

FIG. E2 Axial T2-weighted magnetic resonance imaging scan of a shoulder joint affected by basic calcium phosphate crystal–associated destructive arthritis (Milwaukee shoulder). There is advanced glenohumeral joint degeneration with loss of articular cartilage, truncation of the anterior and posterior labrum, narrowing of the joint space, osteophyte formation, muscle atrophy, and joint effusion. (From Hochberg MC et al: *Rheumatology*, ed 5, St Louis, 2011, Mosby.)

- Calcium stains: Alizarin red stain (highly sensitive–lacks specificity to qualify for routine use), von Kossa stain, or oxytetracycline stain with UV light
- Labeled diphosphonate binding

IMAGING STUDIES

- Plain radiograph: First line. AP and lateral sufficient, but internal or external rotation may be needed for retro humeral deposits
  1. Inert periarticular calcium deposits appear dense, homogenous, without bone trabeculations with well-defined borders
  2. Acute calcific periarthritis attacks appear fluffy with poorly defined margins as crystals shed into surrounding tissues, with soft tissue swelling
- Ultrasonography: Highly sensitive; hyperechoic with posterior acoustic shadowing
- X-ray diffraction, scanning and transmission electron microscope, or Fourier-transform infrared spectroscopy (FTIR)—due to small size (20 to 100 nm)
- CT scan or MRI of affected joint (Fig. E2)

Rx TREATMENT

Asymptomatic deposits: No treatment needed

NONPHARMACOLOGIC THERAPY

Immobilization, ice, range of motion exercises

ACUTE GENERAL Rx

- Analgesics (e.g., acetaminophen), nonsteroidal antiinflammatory drugs (e.g., naproxen or ibuprofen), or colchicine
- Nonselective cyclooxygenase (COX) inhibitors (BCP crystals induce both COX-1 and COX-2)
- Needle aspiration of the deposits or effusions with or without irrigation
- Oral or local intraarticular injection of steroids
- Pain relief with suprascapular nerve blocks, or transcutaneous nerve stimulation

CHRONIC Rx

- Physical therapy
- Pulsed ultrasonography—increased rate of resorption and reduced pain
- Surgical therapy (arthroscopy, arthroplasty, debridement, or joint replacement) may be warranted for restoration of function and pain relief depending on severity

REFERRAL

- Rheumatology
- Orthopedic surgery

PEARLS & CONSIDERATIONS

COMMENTS

Basic calcium phosphate deposition should be considered in the differential diagnosis of acute polyarthritis, especially in the setting of chronic severe OA. Specific crystal identification is difficult with methods that are currently clinically available.

PREVENTION

Bedbug Bite PTG

BASIC INFORMATION

DEFINITION

A bedbug's bite is a wound caused by the penetration of the bedbug mouthpiece into the skin as the insect feeds on blood from vessels or extravasated blood from the damaged surrounding tissue. The saliva of the bedbug contains pharmacologically active substances responsible for a spectrum of undesirable skin reactions depending on the individual. The bugs typically feed during times when an individual is at rest and may feed without being detected. Typically feedings take 5 to 10 minutes.

SYNONYMS

Insect bite
Bedbug *Cimex lectularius* bite

ICD-10CM CODE
T00.9 Multiple superficial (insect bite) injuries, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Traditionally, bedbugs were considered more common in poorer areas, but they are now increasingly found in areas of frequent travel.
- Bedbug infestations may spread among multifamily and institutional facilities with shared walls and are consequently difficult to eradicate.
- Reports of bedbug infestations have increased dramatically in the U.S., as well as worldwide, likely because of the decreased use of pesticides and increased international travel.
- Bedbugs are attracted to carbon dioxide gas and warm bodies.
- Bedbugs do not have a preference for specific age groups, ethnicity, or sex.
- Persons at higher risk include those who have recently stayed overnight in a hotel, dorm room, hospital, or new home.
- Studies have shown increased sensitivity of cutaneous reaction in previous bite victims.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Bites typically occur at night on exposed areas of skin, most often the face, neck, arms, and legs.
- The bites are painless and so do not awaken the individual.
- Onset of signs and symptoms of bites can be immediately on awakening or up to 10 days after the bite.
- Firm, purpuric or erythematous macules, urticaria, papules (Fig. 1), or bullae may be present. Bites are often inflammatory and pruritic, although bedbug-naive individuals may be asymptomatic to their first bites.
- Bite may have a central hemorrhagic punctum.
- Victim may observe a linear series often consisting of three bites ("breakfast, lunch, and dinner").
- Bites are typically pruritic.
- The size, degree of itching, and propensity toward vesiculation all increase with repeated bedbug bites.
- Fig. 2 illustrates symptoms and behaviors resulting from bed bug bites.

ETIOLOGY

- The *Cimex lectularius* species, also known as the common bedbug (Fig. 3), have flat, oval bodies and retroverted mouth parts used for taking blood meals. It feeds on mammals and birds. *Cimex hemipterus* is a tropical species that bites mostly humans, and hybrid species of the two insects exist. Both generally feed nocturnally on the blood of sleeping humans. They hide in beds, the floor, or furniture crevices during the day and emerge at night. They go through a larva stage (Fig. 4) and have a life span from 4 months up to 1 yr. The adult bedbug is wingless and about 5 to 7 mm in length. It has a modified mouthpart for piercing and sucking that usually leaves a bite mark of papular urticarial presentation to exposed areas of skin. Bedbugs have weak appendages for latching on to their hosts and are not usually transported from person to person.
- The saliva of the bedbug contains nitrophorin that enables vasodilation, an anticoagulant that interferes with production of coagulation factor Xa, a salivary apyrase that inhibits platelet aggregation, and an anesthetic. Consequently, the host often does not feel the bite until the effects have worn off.

FIG. 1 Pruritic papules after bedbug bites. (From Kliegman RM et al: *Nelson textbook of pediatrics*, ed 19, Philadelphia, 2011, Saunders.)

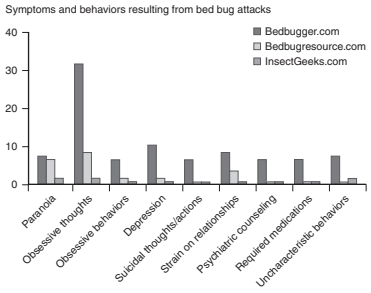

FIG. 2 Distribution of symptoms in 135 Internet reports describing effects of bed bug bites. (From Goddard J, de Shazo R: Psychological effects of bed bug attacks *(Cimex lectularius L.), Am J Med* 125:101-103, 2012.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Scabies, flea and mite bites, vesicular disorders, delusional parasitosis, dermatitis herpetiformis, pemphigus herpetiformis, ecthyma, drug eruptions

WORKUP

- Workup begins with history and physical for clinical symptoms and environmental findings suggestive of insect bites.
- Victims should carefully scrutinize the bedroom for signs of bedbug infestation. One

FIG. 3 Bedbug. (From James WD et al: *Andrews' diseases of the skin*, ed 12, Philadelphia, 2016, Saunders.)

FIG. 4 Bedbug—second-stage larva. (From Habif TP: *Clinical dermatology: a color guide to diagnosis and therapy,* ed 6, Philadelphia, 2016, Elsevier.)

may encounter fecal smears or flecks of blood on bed linens, inside furniture cracks and crevices, and behind peeling wallpaper. Bedbugs may travel as far as 20 feet for a meal. Densely infested rooms may also have a distinctive, pungent, soda syrup–like odor.

LABORATORY TESTS

- No specific tests recommended except for identification of the insect.
- The histology of bedbug bites is similar to other insect bites. Perivascular infiltrate of lymphocytes, histiocytes, eosinophils, and mast cells is seen within the upper dermis. One may also observe collagen bundles with interstitial eosinophils, dermal edema, and extravasated erythrocytes.
- Hypersensitivity to bedbug salivary proteins may be tested via intradermal allergy skin testing.
- Skin biopsy results are nonspecific and are not helpful in making the diagnosis.

IMAGING STUDIES

None

Rx TREATMENT

- Specific treatment of bedbug bites is often not necessary. Bites may self-resolve within a week for milder cases and a few weeks for more severe cases. Treatment regimens are based on resolving symptoms of the bites, mainly pruritus.
- To prevent infection, avoid scratching the area.
- Topical glucocorticoids or systemic antihistamines are appropriate in patients with severe pruritus from the bedbug bite.
  1. Triamcinolone cream 0.1%; apply thin film to affected areas bid.
  2. Chlorpheniramine 4 mg PO at bedtime (adults), 2 mg PO at bedtime (children).
- Insecticides may be effective in eradicating the bedbug, but growing resistance has been seen and multi-insecticide therapy is recommended.
  1. Use permethrin spray for clothing and bedsheets or bed nets.
  2. Diethyltoluamide (DEET): Be wary of toxic levels in children when used at high concentrations.
  3. Deltamethrin and chlorfenapyr are two common insecticides used.
  4. Please consult a pest control professional for safe eradication.

NONPHARMACOLOGIC THERAPY

Vacuuming is effective in removing bedbugs but does not remove the eggs. Wash bedsheets and clothing in hot water with detergent with at least 20 minutes in a dryer. Bedbugs have a high thermal death point of 45° C (113º F) and also may survive at temperatures as low as 7° C (44.6º F). Some companies perform a treatment in which the room is heated above 50° C (122º F), which is a lethal temperature for all stages of a bedbug's life cycle. Coating bedposts with antifriction or adhesive substances such as petrolatum or duct tape may hinder bedbugs from gaining access to the bed.

ACUTE GENERAL Rx

Immunologic response is dependent on immunocompetence and individual sensitivity to the salivary components of the bedbug bite. Often, patients with papular urticaria have IgG antibodies to specific bedbug proteins. IgE antibodies may also mediate bullae formation. Anaphylaxis and death from bites is rare but documented in literature.

DISPOSITION

Patient may resume normal activity and lifestyle. Travelers should inspect their clothing and suitcases before returning home.

BEDBUGS AS POTENTIAL VECTORS

The bedbug has been studied extensively as a potential vector for human pathogens such as HIV, hepatitis B, hepatitis C, and Chagas disease. To date, there is no evidence of transmission from an infected bedbug to a human.

PEARLS & CONSIDERATIONS

COMMENTS

- Bedbugs are an increasing source of anguish and frustration for humans, and clinicians should evaluate for signs of stress and depression.
- A combination of chemical and physical intervention is often necessary for complete eradication. All hiding areas must be carefully inspected and cleaned. Treatment may include pesticides, laundering, heat, freezing, vacuuming, and hiring a professional service to eradicate bedbugs.

Behçet Disease (PTG)

BASIC INFORMATION

DEFINITION

Behçet disease is a chronic, relapsing, inflammatory disorder characterized by the presence of recurrent oral aphthous ulcers, genital ulcers, uveitis, and skin lesions (Fig. E1).

SYNONYM

Behçet syndrome

ICD-10CM CODE
M35.2 Behçet disease

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- Behçet disease is observed in two different geographic locations.
  1. One region consists of Eastern Asia, Turkey, and the Mediterranean basin.
     a. Prevalence ranges from 18 to 30 cases per 100,000 persons.
     b. Turkey has the highest prevalence at 80 to 370 cases per 100,000 persons.
  2. The second region consists of North America and Northern Europe.
     a. Prevalence ranges from 0.5 to 17 cases per 100,000 persons. Germany has the greatest prevalence.
     b. Prevalence of Behçet disease in the U.S. is 0.12 to 0.33 cases per 100,000 persons.
- In these regions, the prevalence of HLA-B51 is greater in patients with Behçet disease.

PREDOMINANT SEX: Equal sex distribution

GENETICS: No clear pattern of inheritance can be determined. Familial disease was noted in 15% of affected children.

AGE: Peak age of onset is between 20 and 40 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Behçet disease typically affects individuals in the third to fourth decade of life and primarily presents with painful aphthous oral ulcers. The ulcers occur in crops measuring 2 to 12 mm and are found on the mucous membrane of the cheek, gingiva, tongue, pharynx, and soft palate.
- Genital and perianal ulcers are similar to the oral ulcers. They may result in scarring.
- Decreased vision secondary to uveitis, keratitis, and retinal artery occlusion with ischemia may be followed by neovascularization, vitreous hemorrhage and contraction, glaucoma, and retinal detachment. Younger male individuals are at greater risk for ocular involvement.
- Skin findings (41% to 97%) include nodular lesions, which are histologically divided into erythema nodosum-like lesions, pseudofolliculitis, papulopustular lesions, acneiform nodules, or pyoderma gangrenosum-like lesions (cutaneous aphthosis).
- Intermittent, symmetric oligoarthritis (40% to 70%) is the most common; ankylosing spondylitis or arthralgias may occur.
- Central nervous system (CNS; 30% in U.S. and 5% in Turkey) meningeal findings including headache, fever, and stiff neck can occur. Cerebellar ataxia, pseudobulbar palsy, and dementia occur with involvement of the brainstem. Vascular involvement (25% to 30%), unique in that it is both arterial and venous, involves vessels of all sizes and may cause systemic arterial vasculitis (aneurysms and occlusions), pulmonary artery vasculitis, venous occlusions (including superficial, deep, cerebral, portal, and mesenteric veins),

FIG. E1 Mucocutaneous manifestations of Behçet disease. A, Oral aphthous ulcers. **B,** Genital ulcers in the scrotum and skin of the shaft of the penis. **C,** Ulcers in the groin *(arrow)* and scars of previous ulcers in the scrotum *(asterisks).* **D,** Skin pathergy response in the forearm as erythematous pustule *(asterisk)* or papule at the needle prick sites at 48 hours. **E,** Pathergic tongue ulcer *(arrow)* induced by dental trauma. **F,** Papulopustular lesions in the calf. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

TABLE E1 Frequencies of Clinical Manifestations of Behçet Disease

Manifestation	Frequency (%)
Mucocutaneous	
Oral aphthous ulcers	97-100*
Genital ulcers	70-90
Papulopustular lesions	70-90
Erythema nodosum–like lesions	40-60
Superficial thrombophlebitis	15-30
Skin pathergy reaction	30-80
Ocular	
Uveitis (bilateral, 80%; unilateral, 20%)	30-50
Musculoskeletal	
Arthritis	40-50
Vascular	
Deep vein thrombosis	10-15
Arterial aneurysms	5
Neurologic involvement	5-10
Parenchymal involvement	80-90
Cerebral sinus thrombosis	10-20
Intestinal involvement	2-30
Family history	3-20

*Frequency may be 80% at disease onset.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

pulmonary embolus, right ventricle thrombosis, and Budd-Chiari syndrome.
- GI involvement is more common in Japanese individuals; ulcerative lesions primarily involve distal ileum and cecum, but any region can be affected. GI lesions tend to perforate or bleed and may recur after surgery.
- Table E1 summarizes frequencies of clinical manifestations of Behçet disease.

ETIOLOGY

The etiology of Behçet disease is unknown. An immune-related vasculitis, a perivascular inflammation, or both are thought to lead to many of the manifestations of Behçet disease. Multiple triggers for this process have been investigated, including herpes simplex virus infection, streptococcal antigen, and others.

Dx DIAGNOSIS

According to the International Study Group for Behçet Disease, the diagnosis of Behçet disease is established when oral ulcerations recur at least three times in one 12-mo period plus at least two of the following conditions in the absence of other systemic diseases:
- Recurrent genital ulceration
- Eye lesions
- Skin lesions
- Positive pathergy test (erythematous papules or pustules [>2 mm in diameter] at sterile needle injection sites after 24 to 48 hours)

DIFFERENTIAL DIAGNOSIS

- Inflammatory bowel disease (ulcerative colitis and Crohn disease)
- Sprue disease
- Herpes simplex infection
- Benign aphthous stomatitis
- Cyclic neutropenia
- Acquired immune deficiency syndrome (AIDS)
- Systemic lupus erythematosus
- Reiter syndrome
- Ankylosing spondylitis
- Hypereosinophilic syndrome
- Sweet syndrome
- Lichen planus
- Pemphigoid

WORKUP

The diagnosis of Behçet disease is a clinical diagnosis. Laboratory tests and x-ray imaging may be helpful in working up the complications of Behçet disease or excluding other diseases in the differential. Commonly used criteria for classification of Behçet disease are summarized in Box E1.

LABORATORY TESTS

No diagnostic laboratory tests for Behçet disease exist. The measurements of T-cell proliferative response to heat shock protein (HSP) and impaired fibrinolytic activity have been proposed for the diagnosis of Behçet disease, but the value of testing has not been confirmed.

IMAGING STUDIES

CT scan, MRI, and angiography are useful for detecting CNS and vascular lesions.

Rx TREATMENT

Treatment is directed at the patient's clinical presentation and complications (e.g., mucocutaneous lesions, ocular lesions, arthritis, GI, CNS, or vascular lesions).

NONPHARMACOLOGIC THERAPY

Supportive care and rest during flares, and moderate exercises such as swimming or walking when symptoms improve or disappear

ACUTE GENERAL Rx

- Oral and genital ulcers:
  1. Topical and intralesional corticosteroids (e.g., triamcinolone acetonide ointment applied tid)
  2. Tetracycline tablets 250 mg dissolved in 5 cc water and applied to the ulcer for 2 to 3 min
  3. Colchicine 0.5 to 1.5 mg/day PO
  4. Thalidomide 100 to 300 mg PO daily
  5. Dapsone 100 mg PO daily
  6. Pentoxifylline 300 mg/day PO
  7. Azathioprine 1 to 2.5 mg/kg/day PO
  8. Methotrexate 7.5 to 25 mg/wk PO or intravenously
  9. Interferon alfa-2a and interferon alfa-2b (generally given 3 to 19 million units three times weekly)
  10. Recent trials have shown that apremilast, an oral phosphodiesterase-4 inhibitor that modulates several inflammatory pathways may be effective in treating oral ulcers (NJEM 372:1510-1518, 2015)
- Ocular lesions:
  1. Anterior uveitis is treated by an ophthalmologist with topical corticosteroids (e.g., betamethasone drops 1 to 2 drops tid); topical injection with dexamethasone 1 to 1.5 mg has also been tried
  2. Infliximab 5 mg/kg single dose
  3. Cyclosporine A (5 mg/kg/day) with or without prednisone or azathioprine 1 to 2.5 mg/kg/day PO
- CNS disease:
  1. Chlorambucil 0.1 mg/kg/day is used in the treatment of posterior uveitis, retinal vasculitis, or CNS disease; patients not responding to chlorambucil can be tried on cyclosporine 5 to 7 mg/kg/day
  2. In CNS vasculitis, cyclophosphamide 2 to 3 mg/kg/day is used. Prednisone can be used as an alternative
- Arthritis:
  1. NSAIDs (e.g., ibuprofen 400-800 mg tid PO or indomethacin 50-75 mg/day PO)
  2. Sulfasalazine 1 to 3 g/day PO is an alternative treatment
- GI lesions:
  1. Sulfasalazine 1 to 3 g/day PO
  2. Prednisone 40 to 60 mg/day PO
- Vascular lesions:
  1. Prednisone 40 to 60 mg/day PO
  2. Cytotoxic agents as mentioned previously
  3. Heparin 5000 to 20,000 U/day followed by oral warfarin

CHRONIC Rx

- Chronic therapy is usually continued for approximately 1 yr after remission.
- Surgery may be indicated in patients with complications of bowel perforation, vascular occlusive disease, and aneurysm formation.
- Mortality is associated with early age of onset, arterial involvement, male gender, and frequent disease flares.

DISPOSITION

- The aphthous oral ulcers last 1 to 2 wk, recurring more frequently than genital ulcers.
- 25% of Japanese patients with ocular lesions become blind.
- The disease course is unpredictable.
- The morbidity of Behçet disease comes primarily from ocular and cutaneous involvement; however, mortality relates primarily to large-size vessel involvement and CNS diseases.

REFERRAL

If the diagnosis of Behçet disease is suspected, a referral to dermatology, rheumatology, and ophthalmology is indicated because the disease is so rare.

PEARLS & CONSIDERATIONS

COMMENTS

- The pathergy test refers to the formation of an erythematous papule or pustule of ≥2 mm

BOX E1 Commonly Used Criteria for Classification of Behçet Disease

Japanese Criteria*

Major Symptoms	Minor Symptoms
Recurrent aphthous oral ulcers	Arthritis
Skin lesions	Intestinal ulcers
Ocular inflammation	Epididymitis
Genital ulcers	Vascular lesions
	Neuropsychiatric disease

Complete patients:
Patients with all four major symptoms during the clinical course

Incomplete patients:
Three major symptoms
Two major and two minor symptoms
Typical recurrent ocular inflammation and one or more major symptoms
Typical recurrent ocular inflammation and two minor symptoms

International study group criteria†:
For a clinical diagnosis of Behçet disease, the patient must have recurrent oral ulceration plus at least two of these additional findings in the absence of any other clinical explanation:

Recurrent oral ulceration:
Minor aphthous, major aphthous, or herpetiform ulcers observed by the physician or reliably described by the patient, which recurred at least three times over a 12-mo period

Recurrent genital ulceration:
Aphthous ulceration or scarring observed by the physician or reliably described by the patient

Eye lesions:
Anterior or posterior uveitis or cells in the vitreous body on slit-lamp examination or retinal vasculitis detected by an ophthalmologist

Skin lesions:
Erythema nodosum, pseudofolliculitis, papulopustular lesions, or acneiform nodules not related to glucocorticoid treatment or adolescence

Positive pathergy test:
Test interpreted as positive by the physician at 24-48 hours

International criteria for Behçet disease‡
Point score system: Scoring 4 indicates diagnosis of Behçet disease

Sign or Symptom	Points
Ocular lesion	2
Genital aphthosis	2
Oral aphthosis	2
Skin lesions	1
Neurologic manifestations	1
Vascular manifestations	1
Positive pathergy test result§	1

after oblique insertion of a sterile 20- or 25-gauge needle into the skin after 24 to 48 hours.
- Because of the rarity of this disease, data from controlled, prospective, randomized clinical trials are lacking.

RELATED CONTENT

Behçet Syndrome (Patient Information)

AUTHOR: **Glenn G. Fort, MD, MPH**

Bell Palsy ALG PTG

BASIC INFORMATION

DEFINITION

Acute peripheral facial nerve (cranial nerve VII) palsy

SYNONYMS

Idiopathic facial paralysis
Facial nerve palsy

ICD-10CM CODE
G51.0 Bell palsy

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 20 to 30 cases per 100,000
PEAK INCIDENCE: Patients less than 70 yr old and pregnant females, especially during the third trimester and first postpartum wk
PREDOMINANT SEX AND AGE: Sexes are equally affected. The median age is 40.
RISK FACTORS: Diabetes and pregnancy

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients present with acute or subacute (hours to days) onset of unilateral facial paralysis with maximal weakness at 3 wk. Clinical findings are dependent on the location of facial nerve injury and involvement of associated branches (Fig. 1). One third of patients demonstrate incomplete paralysis, and the remaining two thirds have complete paralysis. Recovery usually occurs within the first 6 mo.
- Patients may also present with variable involvement of taste over the anterior two thirds of the tongue and/or altered secretion of the lacrimal and salivary glands.

ETIOLOGY

Most cases of Bell palsy are thought to be secondary to either a viral inflammatory or immune injury. Herpes simplex virus is thought to be the most common viral pathogen followed by herpes zoster. Other infectious causes include Epstein-Barr virus, cytomegalovirus, adenovirus, rubella, and mumps.

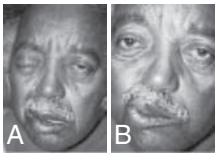

FIG. 1 A patient with a lesion of the facial nerve. A, The patient has difficulty in closing his left eye, and the left corner of his mouth droops. **B,** The latter defect is especially evident when the patient attempts to purse his lips. (From Haines DE: *Fundamental neuroscience for basic and clinical applications,* ed 3, Philadelphia, 2006, Churchill Livingstone.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cortical stroke: Forehead and periorbital muscles are spared in stroke patients because of bilateral innervation of the upper face
- Brain stem stroke: Ipsilateral weakness in the upper and lower muscles of facial expression due to a stroke affecting the nucleus or fascicle of the seventh nerve
- Lyme disease: Facial nerve palsy is the most common cranial neuropathy associated with Lyme disease. In Lyme meningitis, facial nerve palsy may be unilateral or bilateral
- HIV
- Ramsay Hunt syndrome: Facial nerve paralysis associated with ipsilateral zoster oticus
- Parotid gland tumors
- Trauma/temporal bone fracture
- Meningeal processes:
  1. Infectious: Lyme disease, HIV, syphilis, leprosy, tuberculosis meningitis, fungal meningitis
  2. Inflammatory: Sarcoidosis, Sjögren syndrome, and Guillain-Barré syndrome and its variants
  3. Leptomeningeal carcinomatosis or lymphomatosis: Breast cancer, lung cancer, and lymphoma are most common
- Möbius syndrome
- Melkersson-Rosenthal syndrome

WORKUP

- Bell palsy is a clinical diagnosis.
- Additional workup may be necessary in patients with an uncertain diagnosis, complete seventh nerve injury, evidence of neurologic dysfunction in addition to seventh nerve injury, and lack of recovery.

LABORATORY TESTS

Laboratory tests are not typically recommended. However, if the diagnosis of Bell palsy is in question (e.g., bilateral facial nerve palsy, concern for a secondary etiology), then it is reasonable to pursue the following tests:

- Lyme antibody followed by Western blot for positive cases for confirmation. Consider lumbar puncture for CSF analysis for Lyme serologies
- ACE level
- Glycosylated hemoglobin (HgA1C)
- HIV
- RPR and VDRL in CSF
- ESR

ELECTRODIAGNOSTIC TESTING

Electrodiagnostic testing may be performed 2 wk after the onset of symptoms to assess the integrity of a motor unit and the degree of nerve damage. Facial motor response remains normal for the first 3 days following an injury and then rapidly decreases depending on the severity of the lesion. A facial motor study may be performed at 10 days and compared to the contralateral side. A motor response that is 10% the amplitude of the unaffected side on electrodiagnostic testing corresponds with 90% motor axon degeneration. One study found that patient recovery was poor when this critical value was reached.

IMAGING STUDIES

Imaging studies are not usually indicated.

- Brain MRI is indicated in certain cases, such as an upper motor neuron pattern (able to wrinkle forehead) where the temporalis branch of the facial nerve is spared.
- Brain MRI with gadolinium is indicated either when other cranial nerve palsies are present or when a meningeal process is suspected.
- CT temporal bone is indicated in cases of either trauma or complete facial paralysis in which the surgeon is considering decompression.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Reassurance that most patients will have a full recovery and that the patient did not sustain a stroke.
- Eye patch to prevent corneal drying/abrasion and subsequent ulceration. Patients may protect their eyes with Lacri-Lube at night and artificial tears during the day.
- Acupuncture with needle manipulation and strong stimulation has been shown to improve recovery after Bell palsy when compared to acupuncture without needle manipulation.[1]

ACUTE GENERAL Rx

- Corticosteroids started within 72 hr will expedite speed and rate of recovery in most patients. Antiviral therapy alone has no benefit.
  1. Two high-quality randomized trials assessed efficacy of early (<72 hr) treatment with glucocorticoids alone, antiviral therapy alone, and combination therapy in the treatment of Bell palsy. Glucocorticoids alone were effective, while antiviral therapy showed no benefit when given either alone or with concomitant glucocorticoid therapy.
  2. The largest study compared groups receiving the following treatments: (a) 60 mg prednisolone daily, (b) 1000 mg valacyclovir three times daily for 1 wk, (c) combination therapy, and (d) placebo. All interventions were administered within 72 hr of presentation.
  3. Time to recovery, determined at a 1-yr follow-up appointment, was shortest in the group treated with prednisolone monotherapy. The efficacy of valacyclovir

[1]Xu SB et al: Effectiveness of strengthened stimulation during acupuncture for the treatment of Bell palsy: a randomized controlled trial, *CMAJ* 185:473-479, 2013.

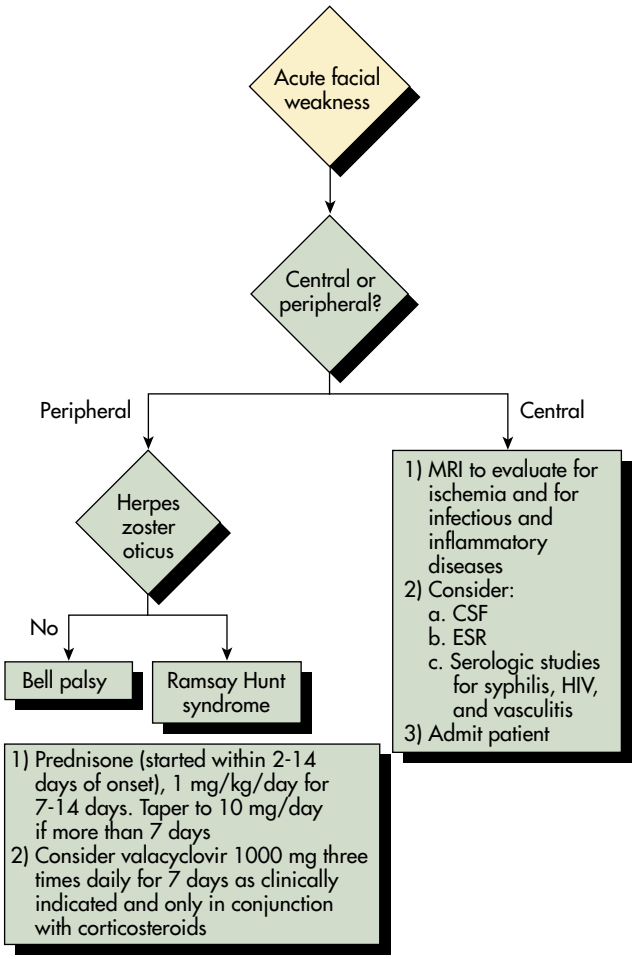

FIG. 2 Algorithm outlining the treatment of patients with Bell palsy. *CSF,* Cerebrospinal fluid; *ESR,* erythrocyte sedimentation rate; *HIV,* human immunodeficiency virus; *MRI,* magnetic resonance imaging. (Modified from Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, St Louis, 2013, Elsevier.)

monotherapy did not differ from placebo, and no added benefit was seen with combination therapy.

- Treatment guidelines recommend prednisone 60 to 80 mg daily for 1 wk.
  1. Despite the lack of strong clinical evidence, some authors still recommend treatment with valacyclovir (1000 mg 3 times daily for 1 wk) in severe cases (i.e., level IV or greater on the House-Brackmann grading system).
- Surgical decompression is not currently recommended.
  1. The 2001 American Academy of Neurology Practice Parameter concluded there was insufficient evidence to make any recommendation regarding surgical decompression for Bell palsy.
  2. This conclusion was further substantiated by a 2011 Cochrane systematic review, which looked at two additional studies, again citing insufficient evidence regarding surgical decompression for Bell palsy.
- Fig. 2 describes an algorithm for the treatment of patients with Bell palsy.

CHRONIC Rx

Botulinum toxin may be used in cases of hemifacial spasm that may follow recovery from Bell palsy.

DISPOSITION

- Between 70% and 90% of patients with Bell palsy have a complete recovery within a few weeks.
- 85% show recovery after 3 wk. Prognosis is favorable if recovery is seen during this timeframe.
- 13% have slight sequelae, and 16% have residual weakness, synkinesis, or contracture.
- Recurrence rate is 7%, and the average time to recurrence is 10 yr.

FIG. 3 Bell palsy. The patient with Bell palsy (facial nerve palsy) will demonstrate an unwrinkled forehead, widely opened eyes (with weakness of eyelid closure), flattening of the nasolabial fold, and a droop of the corner of the mouth. (From Remmel KS et al: *Handbook of symptom-oriented neurology,* ed 3, St Louis, 2002, Mosby.)

REFERRAL

- Neurologist if clinical diagnosis is in question
- Ophthalmologist if concern for corneal abrasion or ulceration

PEARLS & CONSIDERATIONS

COMMENTS

- Assess wrinkling of forehead (Fig. 3). If present on affected side, ensure that the facial weakness is not central.
- Assess for strength of eye closure. A patient with Bell palsy will have difficulty with ipsilateral eye closure, whereas a patient with a central lesion with have equal eye closure strength bilaterally.
- Assess for other cranial nerve deficits or long-tract signs because brain stem fascicular lesions of the seventh nerve can show peripheral facial pattern of weakness.

Benign Paroxysmal Positional Vertigo ALG

BASIC INFORMATION

DEFINITION

Benign paroxysmal positional vertigo (BPPV) is a labyrinthine disorder and is the most common cause of vertigo. It is characterized by paroxysms of brief spinning sensation accompanied by nystagmus that usually last less than a minute. These paroxysms are generally induced by changes in head position with respect to gravity.

SYNONYM

BPPV

ICD-10CM CODE
H81.1 Benign paroxysmal vertigo

EPIDEMIOLOGY & DEMOGRAPHICS

Higher prevalence seen in elderly and women.
INCIDENCE: Incidence increases with advancing age. Unrecognized BPPV can be found in about 10% of certain geriatric populations, and there is a cumulative incidence of nearly 10% by age 80 yr.
PREVALENCE: Lifetime prevalence is 2.4%. Reported prevalence is 10.7 and 64 cases per 100,000 population. BPPV is by far the most common type of vertigo.
PREDOMINANT SEX AND AGE: Female (2:1 to 3:1 ratio); peak onset: 50 to 60 yr.
GENETICS: Unknown
RISK FACTORS: Head trauma, inner ear surgery, viral labyrinthitis, Ménière disease, migraine. The majority are idiopathic.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Brief paroxysms of vertigo and nystagmus with certain head positions are seen in 70%.
- Episodes are typically triggered by head position changes such as while getting in or out of bed, rolling over in bed, tilting the head forward, or bending forward.
- Episodes are brief, usually lasting 30 to 40 seconds but can recur for several days or months.
- Usually no hearing abnormalities are present.
- Direction of nystagmus depends on the canal affected with reversal of direction being seen while sitting up, and fatigability with repeated testing.
- Rarely persistent vertigo and disequilibrium may be seen.

POSTERIOR SEMICIRCULAR CANAL (PSC)

While posterior, horizontal or superior semicircular canal can be affected as isolated or in different combinations, PSC involvement is most common (60% to 90%) and will be discussed in the following sections. Nystagmus is up-beating and torsional and can be elicited by the Dix-Hallpike maneuver.
DIX-HALLPIKE MANEUVER: With head turned to one side at an angle of 45 degrees, patient is moved rapidly from sitting to supine position with head hanging below the end of the table at an angle of 15-20 degrees. The posterior semicircular canal comes into the sagittal plane and the free floating otolith debris moves down and away from the ampulla. An up-beating and torsional nystagmus will be seen with the top poles of the eye beating towards the lower ear.

HORIZONTAL SEMICIRCULAR CANAL

Involvement may be underestimated as it may remit spontaneously. It produces either geotropic nystagmus beating towards the ground or apogeotropic nystagmus beating towards the ceiling when the head is turned to either side in the supine position. The nystagmus beats stronger towards the affected ear.
HEAD ROLL TEST FOR THE RIGHT HORIZONTAL SEMICIRCULAR CANAL (INDUCING GEOTROPIC NYSTAGMUS): Patient is moved from sitting to supine position, then head is rolled 90 degrees to the left. The otolithic debris moves away from the cupula of horizontal semicircular canal, a left beating geotropic nystagmus (towards the ground) is seen. Next the head is turned 90 degrees to the right—a right-beating stronger geotropic nystagmus is seen as otolithic debris moves towards the cupula of the right horizontal semicircular canal.
SUPINE HEAD ROLL TEST FOR THE RIGHT HORIZONTAL SEMICIRCULAR CANAL (INDUCING APOGEOTROPIC NYSTAGMUS): Patient is moved from sitting to supine position, then head is rolled 90 degrees to the left. This induces deflection of the cupula of the right horizontal semicircular canal due to otolithic debris near or attached to the cupula. A strong, right-beating apogeotropic nystagmus (towards the ceiling) is induced. Next, the head is turned 90 degrees in the opposite direction. Now the right horizontal semicircular canal cupula is deflected in the opposite direction and a weak, left-beating apogeotropic nystagmus results.

ANTERIOR SEMICIRCULAR CANAL

Involvement is rare as it is located uppermost in the labyrinth and so otolithic debris is unlikely to become trapped. A downbeat and torsional nystagmus where the top poles of the eye beat towards the lower ear is seen. Evaluating for central lesions is a must in these cases.

ETIOLOGY

The fundamental pathologic process is believed to be the movement of otolithic debris in the endolymph of the inner ear. The debris may be present in the cupula (cupulolithiasis) or free floating within the semicircular canal near the cupula (canalithiasis). Static head position changes with respect to gravity, causing the debris to move within the semicircular canal and creating a false sense of rotation.

DIAGNOSIS

Elicitation of a typical nystagmus with Dix-Hallpike is the standard for diagnosing posterior canal BPPV. However, 25% of symptomatic patients may not exhibit nystagmus. Appropriate referral to a neurologist or neuro-otologist should be considered in these cases.

Fig. E1 shows a diagnostic algorithm for vertigo and dizziness.

DIFFERENTIAL DIAGNOSIS

- Vestibular neuritis
- Vestibular migraine
- Ménière disease
- Stroke
- Box 1 lists causes of vertigo with and without hearing loss
- Table 1 describes the differential diagnosis of true vertigo

WORKUP

None; BPPV is a clinical diagnosis.

IMAGING STUDIES

To be obtained only when stroke remains high in the differential diagnosis

TREATMENT

- BPPV usually resolves without treatment in 2 to 4 wk. Recurrences are common in the first yr, and long-term recurrence rates range from 30% to 50%.
- Nausea and vomiting may be treated symptomatically with medications.
- Canalith repositioning maneuvers (Epley and Semont maneuvers for the posterior canal) are effective. They are designed to "flush" otolithic debris out of the semicircular canals into the vestibule where they are resorbed. Epley maneuver for BPPV of the posterior canal is recommended as standard of care by the American Academy of Neurology and American Academy of Otolaryngology-Head and Neck Surgery. When patients do not respond, it may be related to the technique,

BOX 1 Causes of Vertigo with and without Hearing Loss

Hearing Loss
Conductive
- Otitis media with effusion
- Chronic suppurative otitis media or cholesteatoma should be considered

Sensorineural
- Perilymphatic fistula
- Tumor
- Ménière disease
- Migraine headache
- Genetic syndromes
- Temporal bone fracture
- Vestibular concussion

No Hearing Loss
Acute Vertigo
- Perilymphatic fistula
- Benign positional vertigo
- Seizure
- Labyrinthitis

Recurrent or Chronic Vertigo
- Acoustic neuroma
- Multiple sclerosis

TABLE 1 Differential Diagnosis of Patients with True Vertigo

Cause	History	Associated Symptoms	Physical
Peripheral			
1. Benign paroxysmal positional vertigo	Short-lived, positional, fatigable episodes	Nausea, vomiting	Single position can precipitate vertigo. Horizontorotary nystagmus often can be induced at bedside
2. Labyrinthitis			
• Serous	Mild to severe positional symptoms. Usually coexisting or antecedent infection of ear, nose, throat, or meninges	Mild to severe hearing loss can occur	Usually nontoxic patient with minimal fever elevation
• Acute suppurative	Coexisting acute exudative infection of the inner ear. Severe symptoms	Usually severe hearing loss, nausea, vomiting	Febrile patient showing signs of toxicity. Acute otitis media
• Toxic	Gradually progressive symptoms: Patients on medication causing toxicity	Hearing loss that may become rapid and severe, nausea and vomiting	Hearing loss. Ataxia common feature in chronic phase
3. Ménière disease	Recurrent episodes of severe rotational vertigo usually lasting hours. Onset usually abrupt. Attacks may occur in clusters. Long symptom-free remissions	Nausea, vomiting, tinnitus, hearing loss	Positional nystagmus not present
4. Vestibular neuronitis	Sudden onset of severe vertigo, increasing in intensity for hours, then gradually subsiding over several days. Mild positional vertigo often lasts weeks to months. Sometimes history of infection or toxic exposure that precedes initial attack. Highest incidence is found in third and fifth decades	Nausea, vomiting. Auditory symptoms do not occur	Spontaneous nystagmus toward the involved ear may be present
5. Acoustic neuroma	Gradual onset and increase in symptoms. Neurologic signs in later stages. Most occur in women between 30 and 60	Hearing loss, tinnitus. True ataxia and neurologic signs as tumor enlarges	Unilateral decreased hearing. True truncal ataxia and other neurologic signs when tumor enlarges. May have diminution or absence of corneal reflex. Eighth cranial nerve deficit may be present
Central			
1. Vascular disorders			
• Vertebrobasilar insufficiency	Should be considered in any patient of advanced age with isolated new-onset vertigo without an obvious cause. More likely with history of atherosclerosis. Initial episode usually seconds to minutes	Often headache. Usually neurologic symptoms including dysarthria, ataxia, weakness, numbness, double vision. Tinnitus and deafness uncommon	Neurologic deficits usually present, but initially neurologic examination can be normal
• Cerebellar hemorrhage	Sudden onset of severe symptoms	Headache, vomiting, ataxia	Signs of toxicity. Dysmetria, true ataxia. Ipsilateral sixth cranial nerve palsy may be present
• Occlusion of posterior inferior cerebellar artery (Wallenberg syndrome)	Vertigo associated with significant neurologic complaints	Nausea, vomiting, loss of pain and temperature sensation, ataxia, hoarseness	Loss of pain and temperature sensation on the side of the face ipsilateral to the lesion and on the opposite side of the body, paralysis of the palate, pharynx, and larynx. Horner syndrome (ipsilateral ptosis, miosis, and decreased facial sweating)
• Subclavian steal syndrome	Classic picture is syncopal attacks during exercise, but most cases present with more subtle symptoms	Arm fatigue, cramps, mild lightheadedness may be only other symptoms than vertigo	Diminished or absent radial pulses in affected side or systolic blood pressure differentials between the two areas occur in most patients
2. Head trauma	Symptoms begin with or shortly after head trauma. Positional symptoms most common type after trauma. Self-limited symptoms that can persist weeks to months	Usually mild nausea	Occasionally, basilar skull fracture
3. Neck trauma	Usual onset 7-10 days after whiplash injury. Symptoms may last weeks to months. Episodes seconds to minutes when turning head	Neck pain	Neck tenderness, pain on movement, and positional nystagmus and vertigo when head is turned to side of the whiplash
4. Vertebrobasilar migraine	Vertigo almost always followed by headache. Patient has usually had similar episodes in past. Most patients have a family history of migraine. Syndrome usually begins in adolescence	Dysarthria, ataxia, visual disturbances, or paresthesias usually precede headache	No residual neurologic or otologic signs are present after attack

TABLE 1 Differential Diagnosis of Patients with True Vertigo—cont'd

Cause	History	Associated Symptoms	Physical
5. Multiple sclerosis	Vertigo presenting symptoms in 7%-10% and appears in the course of the disease in a third. Onset may be severe and suggest labyrinth disease. Disease onset usually between ages 20 and 40. Often history of other attacks with varying neurologic signs or symptoms	Nausea and vomiting, which may be severe	May have horizontal, rotary, or vertical nystagmus. Nystagmus may persist after the vertiginous symptoms have subsided. Bilateral internuclear ophthalmoplegia and ataxic eye movements suggest multiple sclerosis
6. Temporal lobe epilepsy	Can be initial or prominent symptom in some patients with the disorder	Memory impairment, hallucinations, trancelike states, seizures	May have aphasia or convulsions
7. Hypoglycemia	Should be considered in diabetics and any other patient with unexplained symptoms	Sweating, anxiety	Tachycardia, mental status change may be present

From Marx JA et al: *Rosen's emergency medicine: concepts and clinical practice,* ed 7, Philadelphia, 2010, Elsevier.

or they may be refractory. There is no clear consensus on how many times the maneuver should be performed at a single visit. Many prefer to do it two or three times if nystagmus is still present with the second maneuver. Other maneuvers such as Barbecue, Vannucchi, and Gufoni are used to reposition debris in the horizontal semicircular canal and will not be discussed here.

EPLEY MANEUVER:

- Head is turned 90 degrees towards unaffected side. The head and trunk are then turned an additional 90 degrees in the same direction, so that the patient lies on the unaffected side with head pointing towards the floor. The otolithic debris moves in the same direction, producing a brief nystagmus. The patient is then moved to a sitting position, which allows the debris to fall out of the canal into the utricle through the common crus.
- Each position should be maintained for 30 seconds or until the nystagmus or vertigo resolves. Sometimes nystagmus in the opposite direction is seen. It is prudent for patients to sit still in the upright position for about 15 minutes and then to walk cautiously.

NONPHARMACOLOGIC THERAPY

Transection of the ampullary nerve (singular nerve) and plugging of the involved canal are rarely performed for intractable and treatment-resistant cases.

ACUTE GENERAL Rx

Canalith repositioning

CHRONIC Rx

If multiple treatments are needed, patients should be instructed to perform the maneuvers at home.

REFERRAL

To a neuro-otologist, otolaryngologist, neurologist

PEARLS & CONSIDERATIONS

- BPPV is a benign and self-limiting condition but can be disabling.
- Diagnosis is clinical and canalith repositioning maneuvers are effective.

PATIENT & FAMILY EDUCATION

- Reassurance
- Fall precautions

BASIC INFORMATION

DEFINITION

Benign prostatic hyperplasia (BPH) is the benign growth of the prostate, generally originating in the periureteral and transition zones, with subsequent obstructive and irritative voiding symptoms. Histologically, BPH refers to the proliferation of smooth muscle, epithelium, and stromal cells within the transition zone of the prostate that surrounds the proximal urethra.

SYNONYMS

Benign prostatic hypertrophy
BPH
Prostatic hypertrophy

ICD-10CM CODES

N40.0	Enlarged prostate without lower urinary tract symptoms
N40.1	Enlarged prostate with lower urinary tract symptoms
N40.2	Nodular prostate without lower urinary tract symptoms
N40.3	Nodular prostate with lower urinary tract symptoms

EPIDEMIOLOGY & DEMOGRAPHICS

- 80% of men have evidence of BPH by age 80 yr.
- Medical and surgical intervention for problems caused by BPH is required in <20% of males by age 75 yr.
- Transurethral resection of the prostate (TURP) is the tenth most common operative procedure (<400,000/yr in U.S.).
- 10% to 30% of men with BPH have occult prostate cancer.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Digital rectal examination (DRE) reveals enlargement of the prostate.
- Focal enlargement may be indicative of malignancy.
- There is poor correlation between size of prostate and symptoms (BPH may be asymptomatic if it does not encroach on the urethral lumen).
- Most patients with BPH report difficulty in initiating urination (hesitancy), decrease in caliber and force of stream, incomplete emptying of bladder often resulting in double voiding (need to urinate again a few minutes after voiding), postvoid "dribbling," and nocturia.

ETIOLOGY

Multifactorial (Fig. E1); a functioning testicle is necessary for development of BPH (as evidenced by the absence in males who were castrated before puberty).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Prostatitis
- Prostate cancer
- Strictures (urethral)
- Medications interfering with the muscle fibers in the prostate and also with bladder function:
  1. Opiates: Impaired autonomic function
  2. Decongestants: Increased sphincter tone
  3. Antihistamines: Decreased parasympathetic tone
  4. Tricyclic antidepressants: Anticholinergic effects
- Neurogenic bladder
- Bladder cancer

WORKUP

Symptom assessment (use of American Urological Association [AUA] Symptom Index for BPH [Table 1]), laboratory tests, and imaging studies. Fig. E2 describes a diagnostic approach to patients with BPH.

LABORATORY TESTS

- Prostate-specific antigen (PSA): Protease secreted by epithelial cells of the prostate; elevated in 30% to 50% of patients with BPH. Testing for PSA increases detection rate for prostate cancer and tends to detect cancer at an earlier stage. However, the PSA test does not discriminate well between patients with symptomatic BPH and those with prostate cancer, particularly if the cancer is pathologically localized and curable. The test may also trigger additional evaluation, including ultrasound biopsy of the prostate. Asymptomatic men with PSA levels >2 ng/ml do not need annual testing. According to the AUA, PSA testing and DRE should be offered to any asymptomatic man <50 yr with a life expectancy of 10 yr. PSA testing can also be offered at an earlier age in men at higher risk of prostatic cancer (e.g., first-degree relatives with prostate cancer; African American race).
- Measurement of "free" PSA is useful to assess the probability of prostate cancer in patients with normal DRE and total PSA between 4 and 10 ng/ml. In these patients

TABLE 1 International Prostate Symptom Score (I-PSS)

	Score						
Symptom	**Not at All**	**Less Than 1 Time in 5**	**Less Than Half the Time**	**About Half the Time**	**More Than Half the Time**	**Almost Always**	**Total Score**
Incomplete emptying: Over the past month, how often have you had a sensation of not emptying your bladder completely after you finished urinating?	0	1	2	3	4	5	
Frequency: Over the past month, how often have you had to urinate again <2 hr after you finished urinating?	0	1	2	3	4	5	
Intermittency: Over the past month, how often have you found you stopped and started again several times when you urinated?	0	1	2	3	4	5	
Urgency: Over the past month, how often have you found it difficult to postpone urination?	0	1	2	3	4	5	
Weak stream: Over the past month, how often have you had a weak urinary stream?	0	1	2	3	4	5	
Straining: Over the past month, how often have you had to push or strain to begin urination?	0	1	2	3	4	5	
	None	1 Time	2 Times	3 Times	4 Times	5 or More Times	
Nocturia: Over the past month, how many times did you most typically get up to urinate from the time you went to bed at night until the time you got up in the morning?	0	1	2	3	4	5	
Total I-PSS score =							

the global risk of prostate cancer is 25%. However, if the free PSA is >25%, the risk of prostate cancer decreases to 8%, whereas if the free PSA is <10%, the risk of cancer increases to 56%. Free PSA is also useful to evaluate the aggressiveness of prostate cancer. A low free PSA percentage generally indicates a high-grade cancer, whereas a high free PSA percentage is generally associated with a slower-growing tumor.
- Elevated measurement of prostate cancer gene 3 (*PCA3*) in urine specimens collected after digital exam is helpful in deciding about prostate biopsy in men with elevated PSA (increased *PCA3* = increased likelihood of prostate cancer).
- Urinalysis, urine culture, and sensitivity to rule out infection (if suspected).
- Blood urea nitrogen and creatinine to rule out postrenal insufficiency.

IMAGING STUDIES

- Transrectal ultrasound may be indicated in patients with palpable nodules or significant elevation of PSA. It is also useful to estimate prostate size. BPH may also be evident in suprapubic ultrasound and MRI (Fig. E3).
- Uroflowmetry may be used to determine relative impact of obstruction on urine flow. Urethral pressure profile is useful to predict prostatic hypertrophy within the urethral lumen.
- Pressure flow studies, although invasive, are particularly helpful in patients whose history and/or examination suggest primary bladder dysfunction as a cause of symptoms of prostatism. They are also useful in patients for whom a distinction between prostatic obstruction and impaired detrusor contractility may affect the choice of therapy. However, pressure flow studies may not be useful in the workup of the usual patient with symptoms of prostatism.
- Postvoid residual urine measurement has not been proved useful in predicting the need for or response to treatment; it may be useful in monitoring the course of the disease in patients who elect nonsurgical treatment.
- Urethral cystoscopy is an option during later evaluation if invasive treatment is being planned.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of caffeine or any other foods that may exacerbate symptoms
- Avoidance of medications that may exacerbate symptoms (e.g., most cold and allergy remedies)

GENERAL Rx

- Asymptomatic patients with prostate enlargement caused by BPH generally do not require treatment. Patients with mild to moderate symptoms are candidates for pharmacologic treatment (see the following). For patients who have specific complications from BPH, prostate surgery is usually the most appropriate form of treatment. However, surgery may result in significant complications (e.g., incontinence, infection).
- Alpha-blockers (e.g., tamsulosin, alfuzosin, doxazosin, prazosin, terazosin) relax smooth muscle of the bladder neck and prostate and can increase peak urinary flow rate. They have no effect on the size of the prostate. Alpha-1 blockers are useful in symptomatic patients to relieve symptoms of obstruction by causing relaxation of smooth muscle tone in the prostatic capsule, urethra, and bladder neck.
- Hormonal manipulation with finasteride, a 5-alpha-reductase inhibitor that blocks conversion of testosterone to dihydrotestosterone, can reduce the size of the prostate. Usual dose is 5 mg qd. Treatment requires ≥6 mo for maximal effect.
- Dutasteride is also a 5-alpha-reductase inhibitor useful to decrease prostate size and improve urinary flow. In addition to inhibiting the isoform of 5-alpha-reductase located in the prostate, the medication inhibits a second isoform and reduces dihydrotestosterone formation in the skin and liver. Usual dose is 0.5 mg qd.
- Tadalafil 2.5 to 5 mg qd has been FDA-approved to treat patients with signs and symptoms of BPH and patients with both ED and signs and symptoms of BPH. Tadalafil can potentiate the hypotensive effect of alpha-blockers and should not be used in combination with alpha-blockers.
- The dietary supplement saw palmetto is commonly used for relief of symptoms of BPH. Recent trials using 160 mg of saw palmetto bid did not improve symptoms of BPH. This contrasts with the positive findings of many previous studies. Trials with higher dose-ranging protocols are currently in progress.
- TURP is the most commonly used surgical procedure for BPH. It is recommended for patients unresponsive to medical therapy who have renal insufficiency, recurrent UTIs, bladder stones, or gross hematuria. Transurethral incision of the prostate (TUIP), a procedure almost equivalent in efficacy, is limited to patients whose estimated resection tissue weight would be 30 g or less. TUIP can be performed in an ambulatory setting or during a 1-day hospitalization. Open prostatectomy is typically performed on patients with very large prostates. A prostatic urethral lift implant (UroLift) is now available for BPH. It is placed transurethrally at the site of obstruction to open the urethra by compressing the obstructing prostatic lobes and holding them permanently retracted with suture-based implants.
- Laser therapy for BPH is a less invasive alternative to TURP; YAG laser enucleation has minimal effect on potency, libido, or patient satisfaction with his sex life and is associated with retrograde ejaculation. However, recent studies indicate that at least in the initial 7 mo after surgery, TURP is moderately more effective than laser therapy in relieving symptoms of BPH.
- Transurethral needle ablation with radiofrequency to remove periurethral prostate tissue is being increasingly used in patients with prostate volume >60 ml and moderate symptoms. It has a low morbidity rate, but treatment failure is approximately 25% at 5 yr and <80% at 10 yr.
- Balloon dilation of the prostatic urethra is less effective than surgery for relieving symptoms but is associated with fewer complications. It is a reasonable treatment option for patients with smaller prostates and no middle lobe enlargement.
- Surgery need not be the treatment of last resort for most patients; that is, patients need not undergo other treatments for BPH before they can have surgery. However, recommending surgery on the grounds that a patient's surgical risk will "only increase with age" is generally inappropriate.

DISPOSITION

With appropriate therapy, symptoms improve or stabilize in <70% of patients with BPH.

REFERRAL

Urology referral for patients with severe or intolerable symptoms and for any patient suspected of having prostate cancer (10% to 30% of men with BPH)

PEARLS & CONSIDERATIONS

COMMENTS

- Emerging technologies for treating BPH, including prostatic artery embolization, transurethral holmium laser enucleation, transurethral electrovaporization, and transurethral microwave thermotherapy of the prostate, appear promising; however, long-term effectiveness has not yet been demonstrated.
- The increase in the use of pharmacologic management has resulted in <30% reduction in the total number of TURP procedures.
- Combined drug therapy for BPH with an alpha-blocker and a 5-alpha-reductase inhibitor is superior to monotherapy with either agent. After 1 yr of combination therapy, withdrawal of the alpha-blocker will usually not exacerbate symptoms.
- Treatment with 5-alpha-reductase inhibitors (finasteride, dutasteride) is associated with approximately 30% higher risk for developing type 2 diabetes.

Biceps Tendonitis

BASIC INFORMATION

DEFINITION

Biceps tendonitis, a frequent cause of shoulder pain, refers to the irritation of the long head of the biceps brachii. The tendon originates at the glenoid, attaching to the glenoid labrum, passing intraarticularly, and entering the biceps groove between the greater and lesser tuberosities of the proximal humerus (Fig. E1). Irritation of the tendon can occur anywhere along the tendon. Degeneration of the tendon may be due to repetitive stress, such as in overhead-throwing athletes, or may result from cumulative effects of traction, friction, shear, and compression of the tendon over time.

SYNONYMS

Bicipital tendonitis
Bicipital tenosynovitis
Biceps tendinosis

ICD-10CM CODES	
M75.20	Bicipital tendinitis of unspecified shoulder
M75.21	Bicipital tendinitis of right shoulder
M75.22	Bicipital tendinitis of left shoulder

EPIDEMIOLOGY & DEMOGRAPHICS

- Prevalence of degenerative biceps tendinopathy in older adults is approximately 0.5 per 100,000 in a 5-yr period.
- Degenerative tendinopathy is more common in male patients than in female patients, at a ratio of 3:1.
- 41% of complete rotator cuff tears have concomitant biceps tendonitis.

RISK FACTORS: Athletes involved in throwing sports, swimming, contact sports, weight lifting, gymnastics, and martial arts are at higher risk, as well as nonathletes performing repetitive overhead movements such as carpenters, electricians, and mechanical wheelchair users.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Biceps tendinopathy is associated with additional shoulder pathology more often than it presents as an isolated pathology, and therefore the diagnosis can be challenging.

- Patients typically complain of progressively worsening pain over the anterior shoulder.
- Pain may radiate from the anterior shoulder down the anterior arm.
- In some patients, the tendon may subluxate or dislocate from the bicipital groove, which is often felt as an uncomfortable "click" in the anterior shoulder.
- Point tenderness over the bicipital groove is commonly present, especially with 10 degrees of internal rotation of the shoulder.
- A positive Yergason test (pain with resisted supination with the elbow at 90 degrees) is suggestive.
- A positive Speed test (pain in the bicipital groove on resisted forward flexion of the arm with the palm up and the elbow straight with resolution with the palm down) is suggestive.
- Uppercut and bear-hug tests may also increase the sensitivity of diagnosis.
- A "Popeye" sign (distal migration and bunching of the biceps muscle) suggests rupture of the tendon (Fig. E2).

ETIOLOGY

- A combination of traction, friction, shear, and compression of the tendon may lead to inflammation of the synovial lining covering the tendon.
- In overhead athletes, biceps tendinopathy is more frequently isolated.
- In the older adult population, tendinopathy is frequently associated with impingement and rotator cuff pathology.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rotator cuff tear: Frequently associated, both pathologies may exist
- Calcific tendonitis of the rotator cuff: Acute, intractable pain is more frequently over the lateral shoulder, and calcified inclusions of the cuff tendons may be visible on x-ray
- Glenohumeral osteoarthritis: May be diagnosed by degenerative changes on x-ray
- Septic arthritis: Often acute and associated with effusion, pain with small movements, and elevated inflammatory markers
- Cervical radiculopathy: Typically presents with weakness and/or sensory changes; radicular pain may radiate to the shoulder
- Superior lesion from anterior to posterior or labral tears
- Subacromial bursitis/impingement syndrome
- Acromioclavicular joint arthritis

WORKUP

Diagnosis of biceps tendinopathy may be suspected from history and physical examination

IMAGING STUDIES

- X-rays are important in identifying other causes of pain such as fractures and arthritis. Generally, they should be ordered initially when working up shoulder pain.
- MRI is frequently used to assist in the diagnosis and may demonstrate thickening and increased signal within the tendon. MRI should be obtained with acute trauma to rule out pathologies (e.g., acute rotator cuff tears) that should be addressed immediately for improved outcomes (Fig. E3).

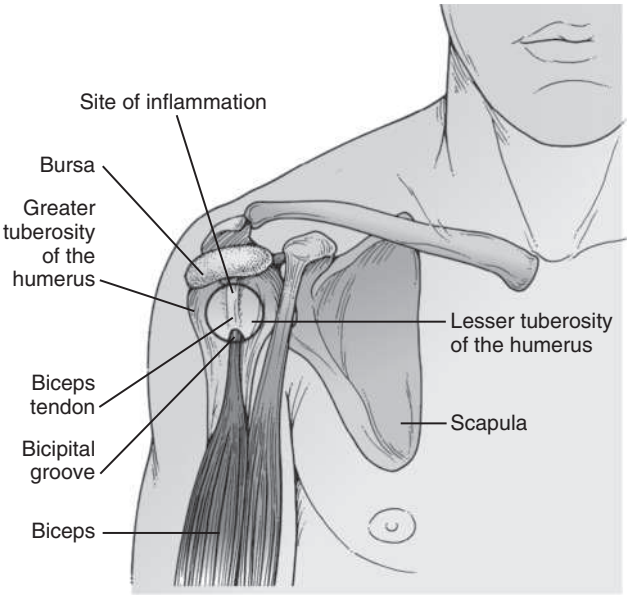

FIG. E1 Anatomic location of the long head of the biceps tendon with surrounding structures of the shoulder. (From Roberts JR et al: *Clinical procedures in emergency medicine,* ed 5, Philadelphia, 2009, WB Saunders.)

FIG. E2 Clinical photograph showing the "Popeye" deformity. (From Hochberg MD: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

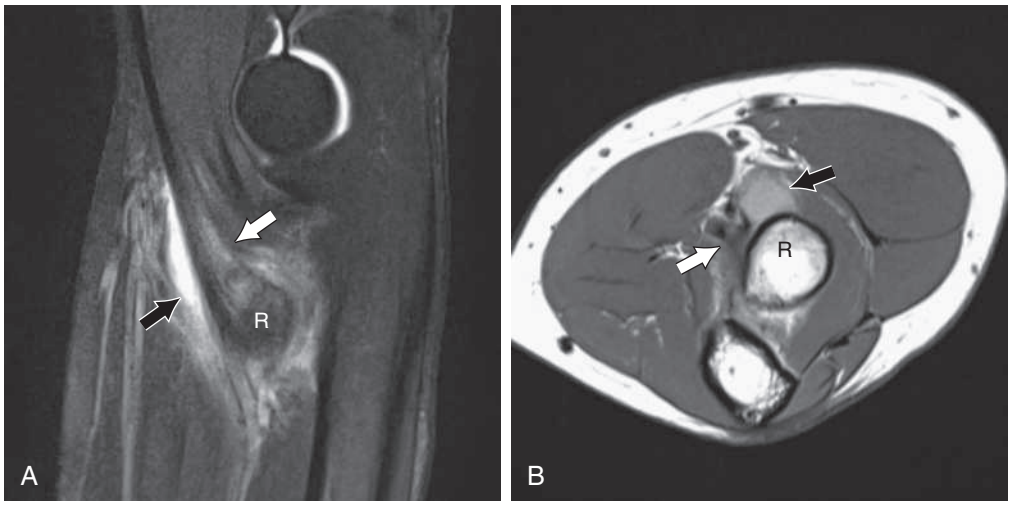

FIG. E3 Distal biceps partial tear. A, Sagittal fat suppressed T2-weighted and **B,** axial proton-density magnetic resonance images demonstrate marked thickening of the discontinuity of the distal biceps tendon short-head fibers associated with increased intrasubstance signal consistent with severe tendinosis *(white arrows).* A distended bicipitoradial bursa is noted *(black arrows). R,* Radial tuberosity. (From Pope TL et al: *Musculoskeletal imaging*, ed 2, Philadelphia, 2014, WB Saunders.)

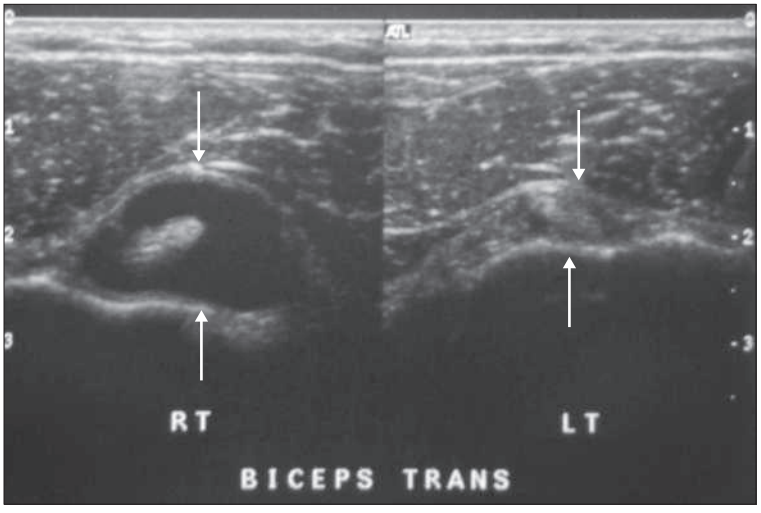

FIG. E4 Ultrasound image of bicipital tendinitis. A transverse image shows a large effusion *(arrows)* in the long head of the biceps tendon sheath. (From Hochberg MD: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

- Ultrasound may reveal the presence of an effusion or absence of the biceps tendon in the intertubercular groove (Fig. E4).
- Subluxation of the tendon may also be seen on MRI or ultrasound.
- Suspicion of tendinopathy can be confirmed with arthroscopy.

Rx TREATMENT

It is often necessary to establish whether the tendonitis is primary or secondary to determine the optimal treatment modalities. Initial conservative treatment is usually very successful.

NONSURGICAL THERAPY

Nonsurgical treatment is typically appropriate in cases not involving acute trauma or other concomitant pathologies requiring immediate intervention. Rest and activity modification, NSAIDs, and physical therapy benefit many patients.

Patients who experience insufficient improvement after a 6- to 8-wk period of conservative treatment may be considered for corticosteroid injection into either the glenohumeral joint or the tendon sheath itself. The tendon should never be directly injected, and ultrasound is recommended as an adjunct to improve accuracy of injections.

SURGICAL TREATMENTS

Surgical management of the biceps tendon may include tenodesis (cutting the tendon and reattaching it at a more distal location along its course) or tenotomy (cutting the tendon without reattaching it distally).

ACUTE GENERAL Rx

Nonsteroidal antiinflammatory drugs (NSAIDs) are good adjuncts to treatment that expedite the recovery process by decreasing edema, inflammation, and pain.

REFERRAL

Consider referral to a physical therapist early in treatment. Patients who do not improve with conservative management over 2 to 3 mo or with acute concomitant pathologies (e.g., acute rotator cuff tear) should be considered for consult to an orthopedic surgeon.

PEARLS & CONSIDERATIONS

COMMENTS

Improved outcomes are noted from surgical fixation of acute tears of the rotator cuff within 6 wk, so prompt workup and referral for these patients is important.

BASIC INFORMATION

DEFINITION

Bicuspid aortic valves (BAVs) are the most common congenital disorder of the heart. It is a result of partial or complete fusion of two of the aortic valve leaflets. Most commonly, fusion of leaflets forms a central raphe, and right and left coronary cusps fuse together. BAV aortopathy results in aortic root and ascending aorta dilation. Aortopathy of the BAV is probably related to rheologic force and shear stress on the aortic wall. It results in cystic medial degeneration of the aortic wall.

SYNONYM

Bicommissural aortic valve

ICD-10CM CODE
Q23.1 Bicuspid aortic valve

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:
- Approximately 1% to 2% of the general population has BAV.
- BAV is the most common cause for valvular aortic stenosis in persons ≤65 yr of age.

PREDOMINANT SEX & AGE: Predominant in males with 2:1 male-to-female ratio.

RISK FACTORS: BAV can be sporadic (more common) and familial. No clear risk factors have been defined. However, multiple clinical conditions are associated with it.
- Coarctation of the aorta
- Turner syndrome
- Shone complex (supravalvular mitral ring, subvalvular aortic membrane, parachute mitral valve, coarctation of the aorta)
- Supravalvular aortic stenosis
- Sinus of Valsalva aneurysm
- Ventricular septal defect

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Symptoms and signs:
- Usually asymptomatic in the young. However, the bicuspid valve degenerates more rapidly than the native tricuspid aortic valve due to rheologic force and shear stress, and causes rapid progression of aortic stenosis. Similar forces on the aortic wall cause aortic root and ascending aorta dilation, which results in aortic aneurysm formation and aortic regurgitation
- Ejection click
- Early peaking ejection systolic murmur
- Early diastolic murmur if aortic root dilated and aortic regurgitation present

ETIOLOGY

It is a common congenital disorder. Embryologically, aortic valve cusps fail to separate, which results in a larger and a smaller cusp.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Subvalvular aortic membrane
- Aortic valvular stenosis
- Supravalvular stenosis

LABORATORY TESTS

No laboratory tests are recommended for diagnosing BAV.

IMAGING STUDIES

- Transthoracic echocardiogram
- Transesophageal echocardiogram
- Cardiac computed tomography angiogram (CCTA)
- Cardiac magnetic resonance angiogram

TREATMENT

- Echocardiographic surveillance is needed to assess progression of bicuspid valve aortic stenosis, regurgitation, and aortic root dilation. If echocardiogram is not optimal to measure aortic root and ascending aorta diameters, consider aortic magnetic resonance angiography or CT angiography. Surveillance interval is determined by the degree and rate of progression of aortic dilation and by family history. Annual surveillance is needed if the aortic diameter is greater than 4.5 cm.
- Surgical aortic valve replacement (SAVR) is indicated for symptomatic BAV disease without aortopathy in low- to intermediate-risk patients.
- Surgical aortic root and/or ascending aorta repair is recommended in patients with BAV disease and aortic aneurysm diameter ≥5.5 cm. SAVR can be considered for moderate to severe BAV stenosis.
- Surgical aortic root and/or ascending aorta repair with valve replacement is recommended in patients with BAV disease and aortic aneurysm diameter of 5.0 cm if there is a family history of dissection or rapid aortic growth (3 to 5 mm/yr) or aortic coarctation, or small stature. SAVR can be considered for moderate to severe BAV stenosis.
- It is reasonable to surgically repair a 4.5 cm aortic root and/or ascending aorta if patient is undergoing SAVR for moderate to severe BAV disease.
- Transcatheter aortic valve replacement (TAVR) is a reasonable option for symptomatic BAV stenosis with reasonable anatomy (no aortopathy) in intermediate and high surgical risk patients. However, Transcatheter Valve Registry data showed higher rates of stroke, annular rupture, and need for permanent pacemakers with TAVR in BAV stenosis compared with tricuspid aortic valve stenosis.
- In 2019 the PARTNER III trial showed significantly lower risk of annual mortality, stroke, or rehospitalization with TAVR compared with SAVR. However, this trial excluded BAV stenosis patients.

REFERRAL

- If BAV disease present, refer to general cardiologist for surveillance
- Heart team approach for management of BAV aortopathy with BAV disease

PEARLS & CONSIDERATIONS

- Most common congenital cardiac abnormality in general population
- Most commonly associated with aortic root and ascending aorta aneurysm
- Close surveillance needed for early diagnosis of disease progression and referral to a cardiac surgeon or formal heart valve team if regurgitation or stenosis becomes severe or symptomatic

PREVENTION

- No clear data on prevention of BAV
- PROCAS and ASTRONOMER trials showed no effect of statin on delay in progression of aortic valve degeneration

PATIENT & FAMILY EDUCATION

Close follow-up with PCP and cardiologist

Binge Eating Disorder (BED)

BASIC INFORMATION

DEFINITION

Binge eating disorder (BED) is characterized by recurrent binge eating episodes, during which an abnormally large amount of food is consumed in a short period of time, accompanied by a sense of loss of control. At least 3 of the following features need to be present in a binge eating episode:

1. Consuming food faster than normal
2. Consuming food until uncomfortably full
3. Consuming large amounts of food when not hungry
4. Consuming food alone due to embarrassment
5. Feeling disgusted, depressed, or guilty after eating a large amount of food

In order to meet criteria for BED, individuals must engage in binge eating episodes at least once per week for 3 months, feel significant distress with regard to their binge eating behaviors, and not utilize compensatory behaviors (e.g., induced vomiting, laxative misuse, overexercising) seen in other eating disorders like bulimia nervosa.

SYNONYMS

Compulsive overeating
BED

ICD-10CM CODE
F50.81 Binge eating disorder
DSM-5 CODE
307.51

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: To our knowledge, no incidence studies on BED yet exist.

PREVALENCE (IN U.S.): Approximately 2% lifetime prevalence in adult community samples was found (women 3.5%; men 2.0%). BED was found to be the most common eating disorder in males—the female:male ratio being more balanced (about 3:2) compared with other eating disorders (about 9:1). Lower lifetime prevalence rates among 13- to 18-yr-old adolescents (girls 2.3%; boys 0.8%) were found. The 12-month prevalence among adult women and men is 1.6% and 0.8%, respectively.

PREDOMINANT AGE (IN U.S.): Higher prevalence rates in females (1.75:1) were found among adults.

GENETICS:

- BED appears to aggregate in families and have a sizable genetic component.
- Family studies report odds ratios between 1.9 and 2.2 for the risk of BED in a relative of a proband with BED compared with relatives of controls.
- Twin studies of BED have reported heritability estimates ranging from 41% to 57% for varying definitions of this disorder.

RISK FACTORS:

- Mental health concerns and psychopathology (mood disorders, anxiety disorders, personality disorders, conduct problems, negative affectivity, substance abuse)
- Temperament and coping style (e.g., high avoidance motivation, low distress tolerance, low extraversion, and self-directedness)
- Severe childhood obesity
- Experience of bullying/weight-related stigmas
- Lifestyle disruptions and deprivation
- Family weight and eating concerns (family dieting, family history of bulimia nervosa, family overeating)
- Quality of parenting (family discord, maternal/paternal problem parenting, parental separation/absence/death)
- Sexual and physical abuse

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Although not necessary for a diagnosis, individuals presenting with BED are often overweight or obese.
- BED is highly comorbid with other forms of psychopathology, especially mood and anxiety disorders. Individuals seeking treatment with acute symptoms of other disorders might not initially report binging episodes, which underscores the importance of thorough initial assessment.
- Males with BED are more likely to underreport symptoms.
- Among individuals with BED, men tend to have significantly higher BMI, whereas women tend to have significantly higher eating-disorder psychopathology.
- Disordered eating symptoms can improve or worsen over time, and diagnostic labels might transition from BED to other eating disorders over time.
- There is potential for higher suicide risk among individuals with BED, possibly because of comorbid psychopathology, and suicidal ideation/intent should be monitored.
- General difficulty to cope with negative emotions and avoidance of aversive experiences/feelings might be apparent.
- Significant shame and self-conscious emotions regarding bingeing behaviors might be present, often resulting in underreporting of binge-eating behaviors.

ETIOLOGY

Research suggests that individual factors (e.g., genetic, biologic, temperamental), environmental factors (e.g., family environment, social network, external sources of stress), and their interactions each contribute.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Important to establish the presence of objective binge eating episodes versus subjective binge eating episodes and nonbinge forms of overeating
- Important to establish that binge eating episodes are not associated with the recurrent use of inappropriate compensatory behaviors (e.g., purging, overexercising)
- Important to establish that binge eating episodes do not occur exclusively during the course of anorexia nervosa, bulimia nervosa, or avoidant/restrictive food intake disorder

WORKUP

- Careful medical and psychosocial history
- Physical examination reveals no specific diagnostic signs of BED
- Mental status examination

LABORATORY TESTS

No laboratory tests are diagnostic. However, given that BED is frequently associated with overweight and obesity, tests examining associated medical problems (e.g., type II diabetes, high triglycerides) might benefit an individual's overall treatment plan.

IMAGING STUDIES

Neuroimaging studies suggest there are corticostriatal circuitry alterations in BED similar to those observed in substance abuse, including altered function of prefrontal, insular, and orbitofrontal cortices and the striatum. Imaging is not recommended as part of routine evaluation.

TREATMENT

NONPHARMACOLOGIC THERAPY

- The primary goal of therapeutic approaches to BED is reduction and/or elimination of binge eating episodes and the associated symptoms of distress.
- Variations of cognitive behavior therapy (CBT) and interpersonal psychotherapy (IPT) remain the most established treatments for BED.
- Growing literature on other psychotherapeutic approaches to BED has also yielded empirical support for dialectical behavior therapy (DBT) and mindfulness-based therapies.
- Combining different interventions at the same time does not add significant advantages. Planning sequential treatments, with more specific interventions for nonresponders, seems to be a more promising strategy.
- Behavioral weight loss (BWL) and self-help interventions evidenced some efficacy in patients with lower psychopathological features. Moreover, BWL approaches have not fared as well as CBT and IPT approaches in ameliorating disordered eating patterns.
- Morbidly obese patients with BED might be well-served by weight loss (bariatric) surgery, which has been found to be associated with sustained, substantial weight loss, as well as reduction in binge eating episodes.
- Preliminary findings regarding electronically delivered psychotherapeutic interventions (e.g., Internet-based CBT) for BED have yielded some empirical support.
- One of the limitations of extant literature is the predominant inclusion of female participants in RCTs.

ACUTE GENERAL Rx

- The pharmacotherapy literature on treating BED in the short-term has focused on

achieving the following objectives: Reducing the frequency of binge eating episodes, reducing weight, and improving associated psychopathology (e.g., depression/anxiety symptoms).
- Preliminary support for specific medications within the classes of antidepressants, anticonvulsants, and antiobesity agents has been found for treating symptoms associated with BED.
- Antidepressants are thought to influence treatment outcomes by addressing the mood and anxiety symptoms that often co-occur with BED. Anticonvulsants have been examined in the treatment of BED because of their success in treating other impulse control disorders. Antiobesity agents have been used to address the overweight and obesity that usually accompanies BED.
- Lisdexamfetamine dimesylate (Vyvanse) is the only medication that has been approved by the Food and Drug Administration (FDA) for the treatment of BED. Two studies found that participants taking the medication experienced a decrease in the number of binge-eating days per week and had fewer obsessive-compulsive binge eating behaviors compared with those on placebo. Longer-term maintenance studies examining the treatment of BED have not yet been published.
- Exploratory work using substance use treatment agents to address BED symptoms is currently under way.
- The existing literature on pharmacotherapy approaches to BED has several limitations, including short duration of RCTs and lack of adequately sized RCTs.

CHRONIC Rx

The long-term treatment of BED using pharmacotherapy has not as yet been systematically investigated.

COMPLEMENTARY & ALTERNATIVE MEDICINE

One study found that hour-long, weekly yoga sessions were associated with reductions in binge eating, BMI, and hip and waist measurements, and an increase in physical activity. More follow-up research is needed in this area.

DISPOSITION

- Data on the long-term outcome of BED, including mortality, are scarce.
- Most outcome data on BED are derived from RCTs. In studies on the outcome of binge eating disorder with a follow-up duration over 3 yr, remission rates in the samples treated with psychotherapy ranged from 19% to 65% across the studies.
- Prospective longitudinal studies with adolescents have found that girls with BED had a twofold risk of becoming overweight or obese, or developing high depressive symptoms compared with nondisordered girls. Among boys, weekly binges predicted drug use as well.
- Various factors may affect treatment response to BED. For instance, higher frequency of binges, increased comorbid psychopathology, and decreased social/family support have been found to be associated with worse treatment outcomes.

REFERRAL

- Referral to mental health specialists: For diagnosis and symptom management (using psychotherapy, pharmacotherapy)
- Referral to nutrition, exercise specialist and/or bariatric surgeon: If patient with BED is morbidly obese and has associated medical problems

PEARLS & CONSIDERATIONS

COMMENTS

- Individuals with BED who are overweight or obese and are interested in weight loss, should also be encouraged to engage in treatment for disordered eating. Although the psychological treatments for BED do not produce substantial weight loss, the elimination of binge eating protects against future weight gain.
- If possible, including family in treatment can be helpful for building social and environmental supports, especially for adolescent and young adult clients.

PREVENTION

There are no known ways to prevent BED (or other eating disorders). However, research suggests that involving education on weight stigma, healthy eating, and body confidence in interventions among school children might ameliorate future body dissatisfaction and disordered eating.

PATIENT & FAMILY EDUCATION

- National Eating Disorders Association (NEDA, www.nationaleatingdisorders.org/) provides patient, family, and professional information on eating disorders, including BED.
- Additional, local and/or online support groups for BED are common and should be investigated.

Bipolar Disorder PTG

BASIC INFORMATION

DEFINITION

Bipolar disorder is an episodic, recurrent, and frequently progressive condition in which the afflicted individual experiences at least one episode of mania, characterized by at least 1 wk of continuous symptoms of elevated, expansive, or irritable mood, in association with three or more of the following symptoms (four if irritability is the presenting mood):

- Decreased need for sleep
- Grandiosity or inflated self-esteem
- Pressured speech
- Flight of ideas or subjective sense of racing thoughts
- Distractibility
- Increased level of goal-directed activity
- Problematic behavior with a high potential for painful consequences

Most individuals with bipolar disorder also experience one or more episodes of major depression over their lifetimes or have symptoms of a depressive episode commingled with those of mania (mixed episode). Hypomanic episodes may also occur.

SYNONYMS

Manic-depression
Cycloid psychosis

ICD-10CM CODES	
F42.0	Bipolar affective disorder, current episode hypomanic
F31.1	Bipolar affective disorder, current episode manic without psychotic symptoms
F31.2	Bipolar affective disorder, current episode manic with psychotic symptoms
F31.3	Bipolar affective disorder, current episode mild or moderate depression
F31.4	Bipolar affective disorder, current episode severe depression without psychotic symptoms
F31.5	Bipolar affective disorder, current episode severe depression with psychotic symptoms
F31.6	Bipolar affective disorder, current episode mixed
F31.8	Bipolar II disorder
DSM-5 CODES	
296.41-296.80	Depends on specific diagnosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 0.016% to 0.021%
PREVALENCE (IN U.S.): 0.4% to 1.6% (lifetime); bipolar spectrum disorders: 2.8%; approximately 25% attempt suicide, and suicide deaths occur 20× more frequently than in the general population
PREDOMINANT SEX: Equal distribution among male and female
PREDOMINANT AGE: Lifelong condition with age of onset 14 to 30 yr
PEAK INCIDENCE: Onset in 20s
GENETICS:

- Concordance rates for monozygotic twins: 0.7 to 0.8; for dizygotic twins: 0.2
- Risk of affective disorder in offspring with one affected parent with bipolar disorder: 27% to 29%; with two affected parents: 50% to 74%
- Heritability estimate of 0.85
- No specific causal mutations have been identified, but cross-disorder studies indicate an overlap with genes associated with a risk for autism or schizophrenia. Genome-wide association analyses and exome sequencing have suggested a role for *CACNA1C, ANK3, TRANK1, ODZ4, ZNF804A,* and *KDM5B,* among others, and have implicated ion channelopathies, immune and neuronal signaling, and histone methylation in pathogenesis of bipolar disorder. It is hypothesized that heritability derives from the additive effect of a number of common risk alleles in association with a few higher-risk deleterious variants

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Mania associated with:
  1. Psychomotor activation that is usually goal directed but not necessarily productive
  2. Increase in goal-directed activity and excessive involvement in activities leading to unexpected adverse outcomes
  3. Elevated, euphoric, and frequently labile mood
  4. Decreased need for sleep
  5. Flight of ideas with rapid, loud, pressured speech
- Psychosis often occurs (75%), with delusions, hallucinations, and/or formal thought disorder
- Depressive episodes resembling major depressive disorder (see "Depression, Major"), although usually of shorter duration and more frequent; atypical features (hypersomnia, prominent anxiety, weight gain) may be present
- Mixed states, characterized by activation, irritability, and dysphoria, also possible.

KEY DIAGNOSTIC CRITERIA DISTINGUISHING BIPOLAR I DISORDER FROM BIPOLAR II DISORDER:

[1]**Manic episode (Bipolar I Disorder)**

- Distinct period during which there is an abnormally and persistently elevated, expansive, or irritable mood and abnormally and persistently increased goal-directed activity or energy lasting at least 1 wk (or less if hospitalization is required)
- Must be accompanied by at least three of the following symptoms (four if mood is only irritable): Inflated self-esteem or grandiosity, decreased need for sleep, pressured speech, racing thoughts, distractibility, increased involvement in goal-directed activity or psychomotor agitation, excessive involvement in pleasurable activities with a high potential for painful consequences
- Symptoms do not meet criteria for a mixed episode
- Disturbance must be sufficiently severe to cause marked impairment in social or occupational functioning or to require hospitalization, or it is characterized by the presence of psychotic features
- Symptoms not due to direct physiologic effect of medication, general medication condition, or substance abuse, although if they persist after a direct condition is addressed, a primary bipolar condition should be considered

Hypomanic episode (Bipolar II Disorder)

- Distinct period during which there is an abnormally and persistently elevated, expansive, or irritable mood and abnormally and persistently elevated activity or energy lasting at least 4 consecutive days
- Must be accompanied by at least three of the following symptoms (four if mood is only irritable): Inflated self-esteem or grandiosity, decreased need for sleep, pressured speech, racing thoughts, distractibility, increased involvement in goal-directed activity or psychomotor agitation, excessive involvement in pleasurable activities with a high potential for painful consequences
- Hypomanic episodes must be clearly different from the person's usual nondepressed mood, and there must be a clear change in functioning that is not characteristic of the person's usual functioning; consider using checklist (HCL-32) for accuracy
- Changes in mood and functioning must be observable by others. In contrast to a manic episode, a hypomanic episode is not severe enough to cause marked impairment in social or occupational functioning or to require hospitalization, and there are no psychotic features
- Symptoms not due to direct physiologic effect of medication, general medication condition, or substance abuse

ETIOLOGY

Hypotheses:

- Abnormalities of GABAA and G protein–coupled receptor and membrane function, calcium dysregulation
- Alteration of cAMP, MAP kinase, protein kinase C, arachidonic acid cascade, and glycogen synthase kinase-3 signal transduction pathways; mitochondrial dysfunction
- Alteration in cell survival pathways, glial and neuronal death and loss of neuroplasticity; proposed biomarkers include BDNF and measures of inflammation, oxidative stress, and endothelial function

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Secondary manias caused by medical disorders (e.g., hyperthyroidism, AIDS, early dementia, stroke and nondominant frontal lobe lesions, Cushing's syndrome) or

[1]Criteria are from the American Psychiatric Association: *Diagnostic and statistical manual of mental disorders, fifth edition,* Washington, DC, 2013, American Psychiatric Association.

pharmacologic treatment (e.g., steroids, stimulants)
- First onset of mania after age 50 yr suggestive of secondary mania
- Less severe, and possibly distinct, conditions of bipolar type II and cyclothymia
- Comorbid substance abuse or dependency occurs in 60% to 75% of patients and may confound diagnosis and treatment
- Presentation can be confused with schizophrenia or paranoid psychosis

WORKUP
- History
- Physical examination
- Mental status examination
- Mood Disorder Questionnaire (MDQ); Composite International Diagnostic Interview (CIDI) (3.0)

LABORATORY TESTS
Because of high rate of secondary manias, initial evaluation to confirm health of all major organ systems (routine chemistries, complete blood count, urinalysis, sedimentation rate)

IMAGING STUDIES
- Consider brain imaging if late onset or if neurologic examination is abnormal.
- Neuroimaging may show evidence of ventricular enlargement or increased white matter hyperintensities; decrements in prefrontal and temporal lobe cortical thickness also reported. Corresponding changes in neurocognition, including changes in executive function, verbal memory, and processing speed, may occur.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY
- Cognitive-behavioral and family-focused psychoeducational psychotherapy to help patients cope with consequences of the disease, improve adherence with medications, and identify possible environmental triggers; consider life charting
- Bright light therapy in the northern latitudes in individuals exhibiting a seasonal pattern of winter depression
- Lifestyle "regularization"; effective sleep hygiene; interpersonal and social rhythm therapy; integrated care management for chronic conditions
- Many smartphone mobile apps for bipolar disorder are available to provide information, help monitor symptoms, and deliver interventions

ACUTE GENERAL Rx
- First-line agents for acute mania and mixed states: Lithium 1500 to 1800 mg/day (0.8 to 1.2 mEq/L), valproate 1000 to 1500 mg/day (50 to 125 ng/ml), carbamazepine 600 to 800 mg/day (4 to 12 micrograms/ml), oxcarbazepine 900 to 2400 mg/day, olanzapine 10 to 20 mg/day, risperidone 2 to 4 mg/day, quetiapine 350 to 800 mg/day, ziprasidone 80 to 120 mg/day, asenapine 10 to 20 mg/day, or aripiprazole 10 to 30 mg/day. Treatment-resistant cases may respond to varying combinations of these agents or to the addition of clozapine.
- Useful adjuncts to acute treatment of mania: Benzodiazepines: lorazepam 1 to 2 mg q4h, clonazepam 1 to 2 mg q4h.
- Traditional antidepressants can induce manic episodes and exacerbate mania in mixed episodes and may be less effective than in treatment of unipolar depression.
- First-line options for bipolar depression include lithium, lurasidone, quetiapine, lamotrigine, and olanzapine/fluoxetine combination. Bupropion may have a lower risk for triggering mania, and monoamine oxidase inhibitors or electroconvulsive therapy may be efficacious in treatment-resistant cases. Off-label agents with possible efficacy include modafinil, pramipexole, and intravenous ketamine.

CHRONIC Rx
- Goal of long-term treatment: Prevention of relapse or episode recurrence
- Best agents for prophylaxis of mania: Lithium, quetiapine, aripiprazole, and olanzapine (valproate, carbamazepine/oxcarbazepine possibly beneficial)
- Best agents for prophylaxis of depression: Lamotrigine and lithium
- Risk/benefit of atypical antipsychotics versus traditional mood stabilizers in maintenance unclear
- Long-term use of antidepressants: Frequently destabilizes patient and leads to more frequent relapses; depression outweighs mania as the most debilitating dimension over the life span; bipolar disorder accounts for 7% of all disease-related disability-adjusted life yrs

DISPOSITION
- Course is variable.
- More than 90% of patients having a single manic episode are likely to experience others.
- Uncontrolled manic or depressive episodes can lead to additional episodes.
- Lithium, in comparison to other mood stabilizers or atypical antipsychotic agents, has been shown to specifically decrease suicidal risk.
- Socioeconomic consequences of both mania and depression can be severe and disabling.
- Mortality rate from all causes is 15× that of the general population.

REFERRAL
- If use of antidepressant contemplated or in cases of pediatric bipolar disorder
- If patient is severely manic, rapid cycling, pregnant, or suicidal or is in a bipolar, mixed episode

! PEARLS & CONSIDERATIONS

COMMENTS
- All patients presenting with depression should be asked about past personal and family history of mania and hypomania; 70% of bipolar patients have previously been misdiagnosed. Onset before age 25, postpartum onset, and poor prior response to antidepressants are additional clues.
- Prompt recognition of the earliest signs of mania in a given individual (e.g., decreased need for sleep, increased rate of speech) allows earlier intervention and a better likelihood of preventing a full episode.
- Bipolar disorder in children frequently manifests as episodic behavioral disinhibition, affective lability, and temper dysregulation, but current consensus indicates that the condition is overdiagnosed in this age group. Disruptive mood dysregulation disorder (DMDD) describes children who exhibit persistent irritability and severe temper outbursts on a frequent basis (at least three times/wk for a yr or more).
- Rapid cycling (greater than three episodes/yr) and mixed states are associated with a poorer prognosis, including a longer course, more treatment resistance, more substance use comorbidity, and increased suicidal risk.
- Patients treated with atypical antipsychotic agents should be carefully monitored for development of metabolic syndrome. Independent of medication effect, there is a higher prevalence of metabolic syndrome and abdominal obesity in those with bipolar disorder.
- Despite some variation in prevalence, the severity, impact, and patterns of comorbidity of bipolar disorder are similar in different countries in world health surveys.
- Bipolar disorder often co-occurs with anxiety disorders and attention deficit hyperactivity disorder (ADHD), making attribution of specific symptoms difficult.
- Patients receiving anticonvulsants or antidepressants should be monitored for a possible increase in suicidal thoughts or behavior.
- There is preliminary evidence that nutraceutical agents like omega-3 fatty acids and *N*-acetyl cysteine (NAC) may have efficacy in the treatment of bipolar disorder.
- Multiple studies show a correlation between bipolar disorder and heightened creativity.
- Patients with bipolar disorder are at risk for catatonic syndrome including manic delirium.

Bite Wounds PTG

BASIC INFORMATION

DEFINITION

A bite wound can be animal or human, accidental, or intentional.

ICD-10CM CODES

T14.1	Open wound of unspecified body region
T01.9	Multiple open wounds, unspecified
S31.000A	Unspecified open wound of lower back and pelvis without penetration into retroperitoneum, initial encounter
S41.159A	Open bite of unspecified upper arm, initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

- Bite wounds account for 1% of emergency department visits, and about 2% of patients need hospitalization.
- More than 1 million bites occur in human beings annually in the U.S.
- Dog bites account for 85% to 90% of all bites and result in 10 to 20 fatalities yearly in the U.S.; most dog bite victims are children. Cat bites account for 10% to 20%. The animal typically is owned by the victim.
- Infection rates are highest for cat bites (30% to 50%), followed by human bites (15% to 30%) and dog bites (5%).
- The extremities are involved in 75% of bites.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The appearance of the bite wound is variable (e.g., puncture wound, tear, avulsion).
- Cellulitis, lymphangitis, and focal adenopathy may be present in infected bite wounds.
- Patient may have fever and chills.

ETIOLOGY

- Increased risk of infection: Human and cat bites, closed-fist injuries, wounds involving joints, puncture wounds, face and lip bites, bites with skull penetration, bites in immunocompromised hosts
- Mixed aerobes and anaerobes typically compose the bacteria in bite wounds. Most frequent infecting organisms:
  1. *Pasteurella* spp.: Responsible for majority of infections within 24 hr of dog *(P. canis)* and cat *(P. multocida, P. septica)* bites
  2. *Capnocytophaga canimorsus* (formerly DF-2 bacillus): A gram-negative organism responsible for late infection, usually after dog bites
  3. Gram-negative organisms *(Pseudomonas, Haemophilus)*: Often found in human bites
  4. *Streptococcus* spp., *Staphylococcus aureus*
  5. *Eikenella corrodens* in human bites

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bite from a rabid animal (often the attack is unprovoked)
- Factitious injury

WORKUP

- Determination of the time elapsed since the patient was bitten, status of rabies immunization of the animal, and underlying medical conditions that might predispose the patient to infection (e.g., DM, immunodeficiency)
- Documentation of bite site, notification of appropriate authorities (e.g., police department, animal officer)
- Box 1 summarizes management procedures for bite wounds

LABORATORY TESTS

- Generally not necessary
- Hematocrit if there has been significant blood loss
- Wound cultures (aerobic and anaerobic) if there is evidence of sepsis or victim is immunocompromised; cultures should be obtained before irrigation of the wound but after superficial cleaning

IMAGING STUDIES

Radiographs are indicated when bony penetration is suspected or if there is suspicion of fracture or significant trauma; they are also useful for detecting foreign bodies (when suspected).

BOX 1 Management Procedures for Bite Wounds

Obtain history from patient:
- Situation leading to injury
- Place of occurrence
- Patient allergies
- Other medications (potential interactions)

Perform evaluation of patient:
- Nerve function
- Tendon function
- Vascular integrity
- Range of motion
- Potential bone and joint involvement

Diagram or photograph wound
Mark leading edge of cellulitis
Culture wound (if infected)
Irrigate wound (do not irrigate puncture wounds)
Debride wound cautiously
Obtain diagnostic imaging for penetrating injuries overlying bones or joints, if fracture suspected or foreign body suspected
Drain abscesses
Operative debridement (for removal of devitalized tissue and for severe bites, as indicated)
Administer antimicrobial agents (prophylactic therapy, 3 to 5 days; longer duration for established infection)
Elevate injured area
Close the wound (see text)
Immobilize wound area (3 days for hands)
Have the patient exercise the injured area (if previously immobilized)
Administer tetanus toxoid
Submit health department report (if required)

Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Local care with debridement, vigorous cleansing, and saline irrigation of the wound; debridement of devitalized tissue
- High-pressure irrigation to clean bite wound and ensure removal of contaminants (e.g., use saline solution with a 30- to 35-ml syringe equipped with a 20-gauge needle or catheter with tip of syringe placed 2 to 3 cm above the wound)
- Avoid blunt probing of wounds (increased risk of infection)
- If the animal is suspected to be rabid: Infiltrate wound edges with 1% procaine hydrochloride, swab wound surface vigorously with cotton swabs and 1% benzalkonium solution or other soap, and rinse wound with normal saline

ACUTE GENERAL Rx

- Avoid suturing of hand wounds and any wounds that appear infected.
- Clenched fist injuries that develop after a punch to another's mouth usually require hospitalization, IV antibiotics, and evaluation by a hand specialist.
- Puncture wounds should be left open.
- Give antirabies therapy and tetanus immune globulin (250 to 500 units IM in limb contralateral to toxoid) and toxoid (adult or child older than 5 yr: 0.5 ml DT given IM, child <5 yr 0.5 ml DPT IM) as needed.
- Use empiric antibiotic therapy in high-risk wounds (e.g., cat bite, hand bites, face bites, genital area bites, bites with joint or bone penetration, human bites, immunocompromised host): Amoxicillin-clavulanate 875 to 1000 mg bid for 7 days or cefuroxime 500 mg bid for 7 days.
- In hospitalized patients, IV antibiotics of choice are cefoxitin 1 to 2 g q6h, ampicillin-sulbactam 1.5 to 3 g q6h, ticarcillin-clavulanate 3 g q6h, cefoxitin 2 g IV q8h, or ceftriaxone 1 to 2 g q24h.
- Penicillin allergy: Animal bite (doxycycline or moxifloxacin or trimethoprim/sulfamethoxazole with either clindamycin or metronidazole); human bite (moxifloxacin plus clindamycin, trimethoprim/sulfamethoxazole plus metronidazole).
- Prophylactic therapy for persons bitten by others with HIV and hepatitis B (see Section V).
- Table 1 summarizes the treatment of mammalian bites. The comparative in vitro antimicrobial activity of selected oral antimicrobial agents against common bite wound pathogens is summarized in Table 2.

DISPOSITION

- Prognosis is favorable with proper treatment.
- Important prognostic factors are type and depth of wound, which compartments are

TABLE 1 Treatment of Mammalian Bites

Type	Wound Care	Antibiotic PR	Tetanus PR	Rabies PR	HIV PR	Hepatitis PR
Human	High-pressure irrigation of the wound with normal saline or dilute (<1%) povidone-iodine solution; débride devitalized tissue or ragged edges	Amoxicillin-clavulanate, second-generation cephalosporin with anaerobic activity, penicillin plus dicloxacillin, clindamycin plus ciprofloxacin or trimethoprim-sulfamethoxazole	Tetanus immunoglobulin (250 units IM) and tetanus toxoid (0.5 mg IM) if never had a tetanus vaccine or have not had 3 doses of tetanus toxoid; tetanus toxoid (0.5 mg IM) if >5 yr since previous tetanus booster	None	ART therapy started within the first 48-72 hr and continued for 28 days or bite source tested HIV negative; refer to the hospital for the specific drugs used in ART therapy	HBIG (0.06 ml/kg IM); HBV given at separate site from HBIG
Cat	High-pressure irrigation of the wound with normal saline or dilute (<1%) povidone-iodine solution; débride devitalized tissue or ragged edges	Amoxicillin-clavulanate, second-generation cephalosporin with anaerobic activity, penicillin plus a first-generation cephalosporin, clindamycin plus a fluoroquinolone or trimethoprim-sulfamethoxazole	Tetanus immune globulin (250 units IM) and tetanus toxoid (0.5 mg IM) if never had a tetanus vaccine or have not had 3 doses of tetanus toxoid; tetanus toxoid (0.5 mg IM) if >5 yr since previous tetanus booster	HRIG (20 IU/kg) injected IM and/or around the bite site; rabies vaccine (1 ml IM) given in the deltoid in adults and in the thigh in children, on days 0, 3, 7, 14, and 28	None	None
Dog	High-pressure irrigation of the wound with normal saline or dilute (<1%) povidone-iodine solution; débride devitalized tissue or ragged edges	Amoxicillin-clavulanate, second-generation cephalosporin with anaerobic activity, penicillin plus a first-generation cephalosporin, clindamycin plus a fluoroquinolone or trimethoprim-sulfamethoxazole	Tetanus immune globulin (250 units IM) and tetanus toxoid (0.5 mg IM) if never had a tetanus vaccine or have not had 3 doses of tetanus toxoid; tetanus toxoid (0.5 mg IM) if >5 yr since previous tetanus booster	HRIG (20 IU/kg) injected IM and/or around the bite site; rabies vaccine (1 ml IM) given in the deltoid in adults and in the thigh in children, on days 0, 3, 7, 14, and 28	None	None

ART, Antiretroviral therapy; *HBIG,* hepatitis B immune globulin; *HBV,* hepatitis B vaccine; *HIV,* human immunodeficiency virus; *HRIG,* human rabies immune globulin; *IM,* intramuscularly; *PR,* prophylaxis.

TABLE 2 Comparative in Vitro Antimicrobial Activity of Selected Oral Antimicrobial Agents against Common Bite Wound Pathogens

	Staphylococcus aureus[a]	*Eikenella corrodens*	*Streptococcus*	*Haemophilus*	*Pasteurella*	Anaerobes
Amoxicillin	–	+	v	v	v	v
Amoxicillin–clavulanic acid	v	+	+	+	+	+
Cephalexin	v	–	v	–	v	–
Cefaclor	v	–	v	v	v	–
Cefuroxime	v	v	v	v	v	–
Meropenem	v	+	+	+	+	+
Dicloxacillin	v	–	v	–	–	–
Erythromycin	v	–	v	–	v	–
Azithromycin	v	v	v	–	v	v
Clarithromycin	v	v	v	–	v	–
Trimethoprim-sulfamethoxazole	+	+	v	+	+	–
Moxifloxacin	+	+	+	+	+	+
Clindamycin	+	–	+	–	–	+

+, Active; *–,* poorly active or inactive; *v,* variable.
[a]Methicillin-resistant *S. aureus* can be a pathogen in bite wounds.
Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases*, ed 8, Philadelphia, 2019, Elsevier.

BOX 2 Advice for Avoiding the Bites and Attacks of Common Pets

Dogs
- Do not leave a young child alone with a dog.
- Never approach or try to pet an unfamiliar dog, especially if it is tied up or confined.
- Always ask the dog's owners if you can pet the dog.
- Do not lean over a dog or pet it directly on the head.
- Do not kiss a dog.
- Avoid quick or sudden movements that may startle a dog.
- Never pet or step over a sleeping dog.
- Never try to take a bone or toy away from a dog (other than your own dog).
- Know the appearance of an angry dog: barking, growling, snarling with teeth showing, ears laid flat, legs stiff, tail up, and hair on the back standing up.
- Never step between two fighting dogs; if you need to separate them, use a bucket of water or a hose.
- Do not approach a female dog that is nursing her pups.
- Teach injury prevention advice to children from an early age.

Cats
- Be aware that some cats do not like prolonged petting.
- Know warning signs of an impending bite: twitching of the tail, restlessness, and "intention" bites (i.e., the cat moves to bite but does not bite).

Ferrets
- Do not sell or adopt a ferret that is known to bite.
- Do not push your fingers through the wires of a ferret cage.
- Reach for a ferret from the side with the palm upward rather than from above.
- Do not handle food and then handle young ferrets without washing your hands first.
- Do not poke a ferret or pull on its tail or ears.
- Never leave a ferret alone with a child or infant.
- If a ferret bites and locks on very tightly, pour cold and fast-running water over its face.

From Auerbach P: *Wilderness medicine, expert consult,* premium edition—enhanced online features and print, Philadelphia, 2012, Elsevier.

entered, and pathogenicity of inoculated bacteria.
- Punctures that are difficult to irrigate adequately, carnivore bites over vital structures (arteries, nerves, joints), and tissue crushing that cannot be debrided have a worse prognosis.
- In general, human bites have a higher complication and infection rate than do animal bites.
- Nearly 50% of the anaerobic gram-negative bacilli isolated from human bite wounds may be penicillin resistant and beta-lactamase positive.

PREVENTION

Box 2 provides advice for avoiding the bites and attacks of common pets.

REFERRAL

- Hospitalization and IV antibiotic therapy for infected human bites; bites with injury to joints, nerves, or tendons; or any animal bites unresponsive to oral therapy.
- Human bites with tendon involvement should go to operating room for washout.
- In the outpatient setting, bite wounds should be reevaluated within 48 hr to assess for signs of infection.

Ellis R, Ellis C: Dog and cat bites, *Am Fam Physician* 90(4):239-243, 2014.

BASIC INFORMATION

DEFINITION

There are two major classes of arthropods: insects and Arachnida. This chapter focuses on the class Arachnida. Arachnid bites consist of bites caused by:

- Spiders
- Scorpions
- Ticks

ICD-10CM CODES

T63.301	Toxic effect of unspecified spider venom, accidental (unintentional), initial encounter
